FortiOS™ Handbook

01-566-497911-20180913

# TABLE OF CONTENTS

<b>Chapter 1 - What's New for FortiOS 5.6</b>	<b>51</b>
What's New for FortiOS 5.6.4	53
Authentication	53
Firewall	53
FortiView	53
FortiWiFi and FortiAP	53
Hardware acceleration	53
High availability	53
IPsec VPN	53
Logging and reporting	53
Security profiles	54
SSL VPN	54
Virtual FortiOS	54
What's New in previous versions of FortiOS 5.6	55
FortiGate VM enhancements for AWS, Azure, Google, SDN connectors and more	55
Fortinet Security Fabric enhancements	55
Security Fabric Audit	55
Re-designed Dashboard	55
NGFW Policy Mode	55
Transparent web proxy	56
Controlled failover between wireless controllers	56
FortiView Endpoint Vulnerability chart	56
FortiClient Profile changes	56
Adding Internet services to firewall policies	56
Source and destination NAT in a single Firewall policy	56
Other highlights	56
New Fortinet Security Fabric features	57
Security Fabric Audit and Fabric Score	68
New Dashboard Features	74
FortiExplorer for iOS	81
Transparent web proxy (386474)	83
NGFW Policy Mode (397035)	91
New FortiView Endpoint Vulnerability Scanner chart (378647)	94
FortiClient Profile changes (386267, 375049)	95

Application Control is now standard with FortiCare support .....	97
Real time logging to FortiAnalyzer and FortiCloud .....	98
FortiGate Logs can be sent to syslog servers in Common Event Format (CEF) (300128).....	99
Controlled failover between wireless controllers.....	99
Multiple PSK for WPA Personal (393320).....	100
Hotspot 2.0 (443988) - FortiOS 5.6.3.....	100
VXLAN support (289354).....	104
New PPPoE features.....	105
Adding Internet services to firewall policies (389951).....	107
Combining source and destination NAT in the same policy (388718).....	108
NP6 Host Protection Engine (HPE) adds protection for DDoS attacks (363398).....	109
New feature catalog (5.6.3, 5.6.1 and 5.6).....	110
Getting Started (5.6.3).....	110
Getting Started (5.6.1).....	111
Getting Started (5.6).....	113
Authentication (5.6.3).....	116
Authentication (5.6.1).....	118
Authentication (5.6).....	121
FortiOS Carrier (5.6.3).....	124
FortiOS Carrier (5.6.1).....	127
Device identification (5.6).....	131
Diagnose command changes (5.6.1).....	132
Diagnose command changes (5.6).....	133
Explicit web proxy (5.6).....	147
Firewall (5.6.3).....	150
Firewall (5.6.1).....	154
Firewall (5.6).....	156
Managed FortiSwitch OS 3.6.0 (FortiOS 5.6.3).....	166
Managed FortiSwitch OS 3.6.0 (FortiOS 5.6.1).....	169
Managed FortiSwitch OS 3.6.0 (FortiOS 5.6).....	176
FortiView (5.6.3).....	178
FortiView (5.6.1).....	178
FortiView (5.6).....	178
FortiGate VM enhancements for AWS, Azure, Google, SDN connectors and more (5.6.3).....	181
FortiGate VM (5.6.0).....	186
Hardware acceleration (5.6.3).....	189
Hardware acceleration (5.6.1).....	190
Hardware acceleration (5.6).....	190
High Availability (5.6.1).....	193
High Availability (5.6).....	194

IPsec VPN (5.6.3).....	198
IPsec VPN (5.6.1).....	200
IPsec VPN (5.6).....	203
IPv6 (5.6.3).....	208
IPv6 (5.6).....	208
Logging and Reporting (5.6.3).....	211
Logging and Reporting (5.6.1).....	212
Logging and Reporting (5.6).....	213
Maximum values changes.....	215
Modem (5.6.1).....	215
Networking (5.6.3).....	219
Networking (5.6.1).....	220
Networking (5.6).....	222
New RFCs.....	227
Sandbox Integration (5.6.1).....	227
Security Fabric (5.6.3).....	228
Security Profiles (5.6.3).....	229
Security Profiles (5.6.1).....	229
Security Profiles (5.6).....	231
Server Load balancing (5.6.1).....	240
Server Load balancing (5.6).....	241
Session-aware Load Balancing (SLBC) (5.6.1).....	243
SSL VPN (5.6.3).....	244
SSL VPN (5.6.1).....	244
SSL VPN (5.6).....	245
System (5.6.3).....	249
System (5.6.1).....	249
System (5.6).....	249
Traffic shaping (5.6.3).....	253
VDOMs (5.6.0).....	254
VoIP/SIP (5.6).....	254
WiFi (5.6.3).....	256
WiFi (5.6.1).....	258
WiFi (5.6).....	260
<b>Chapter 2 - Getting Started.....</b>	<b>269</b>
Differences between Models.....	269
What's New in FortiOS 5.6.....	270
FortiOS 5.6.3.....	270
FortiOS 5.6.1.....	270
FortiOS 5.6.....	272
Changing inspection modes (flow-based or proxy-based).....	279
Transparent Web proxy mode.....	280

NGFW profile-based and NGFW policy-based modes .....	280
Installation .....	283
Quick installation using DHCP .....	284
Installing a FortiGate in NAT/Route mode .....	285
Using a Virtual Wire Pair .....	287
Using the GUI .....	289
Connecting to the GUI using a web browser .....	289
Menus .....	290
Dashboard .....	292
Feature Visibility .....	295
Tables .....	296
Text Strings .....	298
Using the CLI .....	300
Connecting to the CLI .....	300
Command syntax .....	305
Sub-commands .....	308
Permissions .....	312
Tips .....	313
FortiExplorer for iOS .....	321
Getting started with FortiExplorer .....	321
LED Specifications .....	326
Sample FortiGate faceplates .....	326
LED status codes .....	327
About alarm levels .....	328
LED status codes for ports .....	328
Inspection Mode .....	330
Basic Administration .....	334
Registration .....	334
System Settings .....	334
Passwords .....	338
Firmware .....	340
Configuration Backups .....	347
FortiGuard .....	352
FortiCloud .....	360
Troubleshooting your FortiGate Installation .....	362
Resources .....	364
Best Practices .....	364
The Fortinet Cookbook .....	364
The Fortinet Video Library .....	364
The FortiOS Handbook .....	364
<b>Chapter 3 - Authentication .....</b>	<b>365</b>
Whats new in FortiOS 5.6 .....	366

FortiOS 5.6.4.....	366
FortiOS 5.6.3.....	366
FortiOS 5.6.1.....	368
FortiOS 5.6.0.....	371
Introduction to authentication.....	375
What is authentication?.....	375
Methods of authentication.....	375
Types of authentication.....	377
Single Sign-On authentication for users.....	380
User's view of authentication.....	381
FortiGate administrator's view of authentication.....	382
General authentication settings.....	383
Authentication servers.....	384
FortiAuthenticator servers.....	384
RADIUS servers.....	384
LDAP servers.....	391
TACACS+ servers.....	400
POP3 servers.....	402
SSO servers.....	403
RSA ACE (SecurID) servers.....	405
Users and user groups.....	410
Users.....	410
User groups.....	424
Managing Guest Access.....	430
Configuring guest user access.....	430
Guest access in a retail environment.....	432
Configuring authenticated access.....	436
Authentication timeout.....	436
Password policy.....	437
Authentication protocols.....	439
Authentication in Captive Portals.....	440
Authentication in security policies.....	440
Authentication replacement messages.....	441
Kerberos authentication for explicit web and transparent web proxy users.....	446
VPN authentication.....	456
Captive portals.....	461
Introduction to Captive portals.....	461
Configuring a captive portal.....	461
Customizing captive portal pages.....	463
Certificate-based authentication.....	469
What is a security certificate?.....	469
Certificates overview.....	470

Managing X.509 certificates .....	473
Troubleshooting certificates .....	478
Configuring certificate-based authentication .....	482
Support for per-VDOM certificates .....	485
Example — Generate a CSR on the FortiGate unit .....	486
Example — Generate and Import CA certificate with private key pair on OpenSSL .....	487
Example — Generate an SSL certificate in OpenSSL .....	488
Single Sign-On using a FortiAuthenticator unit .....	491
User's view of FortiAuthenticator SSO authentication .....	491
Administrator's view of FortiAuthenticator SSO authentication .....	491
Configuring the FortiAuthenticator unit .....	492
Configuring the FortiGate unit .....	493
Configuring the FortiClient SSO Mobility Agent .....	494
Viewing SSO authentication events on the FortiGate unit .....	494
Single Sign-On to Windows AD .....	495
Introduction to Single Sign-On with Windows AD .....	495
Configuring Single Sign On to Windows AD .....	495
FortiOS FSSO log messages .....	500
Testing FSSO .....	501
Troubleshooting FSSO .....	501
Agent-based FSSO .....	503
Introduction to agent-based FSSO .....	503
FSSO NTLM authentication support .....	509
Agent installation .....	512
Configuring the FSSO Collector agent for Windows AD .....	517
Configuring the FSSO TS agent for Citrix .....	529
Configuring FSSO with Novell networks .....	530
Configuring FSSO Advanced Settings .....	532
Configuring FSSO on FortiGate units .....	537
FortiOS FSSO log messages .....	543
Testing FSSO .....	545
Troubleshooting FSSO .....	545
SSO using RADIUS accounting records .....	548
User's view of RADIUS SSO authentication .....	548
Configuration Overview .....	548
Configuring the RADIUS server .....	548
Creating the FortiGate RADIUS SSO agent .....	549
Defining local user groups for RADIUS SSO .....	551
Creating security policies .....	552
Example: webfiltering for student and teacher accounts .....	553
Monitoring authenticated users .....	556
Monitoring firewall users .....	556

Monitoring SSL VPN users.....	556
Monitoring IPsec VPN users.....	557
Monitoring users Quarantine.....	557
Examples and Troubleshooting.....	559
Firewall authentication example.....	559
LDAP Dial-in using member-attribute example.....	565
RADIUS SSO example.....	567
Troubleshooting.....	574
<b>Chapter 4 - Best Practices.....</b>	<b>576</b>
Introduction.....	576
General Considerations.....	576
Customer service and technical support.....	576
Fortinet Knowledge Base.....	576
System and performance.....	578
Performance.....	578
Shutting down.....	578
Migration.....	579
Information gathering.....	579
Object and policy migration.....	579
Testing and validation.....	579
Going live and obtaining feedback.....	580
Adding new services.....	580
Environmental specifications.....	581
Grounding.....	581
Rack mounting.....	581
Firmware.....	583
Firmware change management.....	583
Performing a firmware upgrade.....	586
Performing a firmware downgrade.....	587
Performing a configuration backup.....	587
Security Profiles (AV, Web Filtering etc.).....	590
Firewall.....	590
Security.....	590
Authentication.....	591
Antivirus.....	591
Antispam.....	591
Intrusion Prevention System (IPS).....	591
Email filter.....	592
amURL filtering.....	592
Web filtering.....	593
Patch management.....	593
Policy configuration.....	593

Networking.....	595
Routing configuration.....	595
Advanced routing.....	595
Network Address Translation (NAT).....	596
Transparent Mode.....	596
Using Virtual IPs (VIPs).....	596
FGCP High Availability.....	597
Heartbeat interfaces.....	597
Interface monitoring (port monitoring).....	598
WAN Optimization.....	599
Virtual Domains (VDOMs).....	601
Per-VDOM resource settings.....	601
Virtual domains in NAT/Route mode.....	601
Virtual clustering.....	601
Explicit proxy.....	602
Wireless.....	603
Encryption and authentication.....	603
Geographic location.....	603
Network planning.....	603
Lowering the power level to reduce RF interference.....	604
Wireless client load balancing.....	604
Local bridging.....	604
Advertising SSIDs.....	605
Using static IPs in a CAPWAP configuration.....	605
Logging and reporting.....	606
Log management.....	606
System memory and hard disks.....	607
<b>Chapter 5 - FortiOS Carrier.....</b>	<b>608</b>
What's New in FortiOS 5.6.....	608
New features added in 5.6.3.....	608
New features added in 5.6.1.....	611
Overview of FortiOS Carrier features.....	615
Overview.....	615
MMS.....	615
GTP.....	615
MMS Concepts.....	615
MMS background.....	615
How FortiOS Carrier processes MMS messages.....	619
MMS protection profiles.....	629
Bypassing MMS protection profile filtering based on carrier endpoints.....	630
Applying MMS protection profiles to MMS traffic.....	630
MMS Configuration.....	630

MMS profiles.....	630
MMS Content Checksum.....	645
Notification List.....	646
Message Flood.....	648
Duplicate Message.....	650
Carrier Endpoint Filter Lists.....	651
Message flood protection.....	654
Duplicate message protection.....	665
Employing MMS Security features.....	672
GTP basic concepts.....	686
PDP Context.....	687
GPRS security.....	688
Parts of a GTPv1 network.....	689
Radio access.....	690
Transport.....	690
Billing and records.....	693
GPRS network common interfaces.....	694
GTP Configuration.....	695
Introduction to GTP.....	695
GTP Profile.....	697
Configuring GTP on FortiOS Carrier.....	717
GTP message type filtering.....	724
GTP identity filtering.....	731
SCTP Concepts.....	737
SCTP Firewall.....	739
Troubleshooting.....	741
FortiOS Carrier diagnose commands.....	741
Applying IPS signatures to IP packets within GTP-U tunnels.....	742
GTP packets are not moving along your network.....	743
<b>Chapter 6 - PCI DSS Compliance.....</b>	<b>748</b>
FortiOS 5.4 PCI DSS compliance new features.....	748
Configuring FortiGate units for PCI DSS compliance.....	749
Introduction to PCI DSS.....	749
Running PCI DSS compliance checks.....	751
Network topology.....	753
Security policies for the CDE network.....	755
Wireless network security.....	756
Protecting stored cardholder data.....	758
Protecting communicated cardholder data.....	758
Protecting the CDE network from viruses.....	759
Monitoring the network for vulnerabilities.....	760
Restricting access to cardholder data.....	760

Controlling access to the CDE network .....	761
<b>Chapter 7 - Firewall .....</b>	<b>764</b>
Fundamentals .....	764
FortiGate Firewall Components .....	764
Firewall Optimization .....	765
How does a FortiGate Protect Your Network? .....	766
What's new for Firewall in 5.6 .....	767
New Firewall Features in 5.6.4 .....	767
New Firewall Features in 5.6.3 .....	767
New Firewall Features in 5.6.1 .....	771
New Firewall Features in 5.6.0 .....	773
New WAN Optimization Features in 5.6 .....	783
New Proxy Features in 5.6 .....	784
Firewall concepts .....	787
What is a Firewall? .....	787
FortiGate Modes .....	790
How Packets are handled by FortiOS .....	791
Interfaces and Zones .....	792
Access Control Lists .....	794
Firewall policies .....	794
Policy Modes .....	802
Security profiles .....	805
IPv6 .....	815
NAT .....	818
IP Pools .....	831
Services and TCP ports .....	834
VPN Policies .....	860
DSRI .....	860
Interface Policies .....	861
DoS Protection .....	862
Local-In Policies .....	867
Security Policy 0 .....	868
Deny Policies .....	869
Accept Policies .....	869
Fixed Port .....	869
Endpoint Security .....	870
Traffic Logging .....	870
Network defense .....	872
Monitoring .....	872
Blocking external probes .....	872
Defending against DoS attacks .....	877
Inside FortiOS: Denial of Service (DoS) Protection .....	881

About DoS and DDoS attacks.....	881
FortiOS DoS and DDoS protection.....	881
FortiOS DDoS Prevention.....	882
Configuration options.....	883
DoS policies.....	884
Hardware acceleration.....	884
The FortiGuard Center.....	884
Firewall Policies.....	885
Viewing Firewall Policies.....	885
Policy Names.....	887
IPv4 Policy.....	888
IPv6 Policy.....	892
NAT64 Policy.....	894
NAT46 Policy.....	895
Central SNAT.....	897
IPv4 Access Control List.....	900
IPv6 Access Control List.....	900
IPv4 DoS Policy.....	901
IPv6 DoS Policy.....	906
Multicast Policy.....	908
Object Configuration.....	910
UUID Support.....	911
Addresses.....	912
Virtual IPs.....	932
Configuring IP pools.....	939
Services.....	944
Firewall schedules.....	951
Secure Web Gateway, WAN Optimization, Web Caching and WCCP.....	957
Before you begin.....	957
FortiGate models that support WAN optimization.....	957
Distributing WAN optimization, explicit proxy, and web caching to multiple CPU Cores.....	957
Toggling Disk Usage for logging or wan-opt.....	957
Example topologies relevant to WAN Optimization.....	959
Basic WAN optimization topology.....	959
Out-of-path WAN Optimization topology.....	960
Topology for multiple networks.....	961
WAN optimization with web caching.....	962
Explicit Web proxy topologies.....	963
Explicit FTP proxy topologies.....	963
Web caching topologies.....	964
WCCP topologies.....	964
Inside FortiOS: WAN Optimization.....	965

Centralize without compromising your WAN performance .....	965
FortiOS WAN Optimization .....	965
Protocol optimization .....	966
Web caching .....	966
Byte caching .....	967
Server Monitoring and Management .....	967
SSL acceleration .....	967
VPN replacement .....	967
Road warriors and home workers .....	968
WAN Optimization Concepts .....	968
Client/server architecture .....	968
WAN optimization peers .....	969
Protocol optimization .....	970
Protocol optimization and MAPI .....	970
Byte caching .....	971
WAN optimization transparent mode .....	971
FortiClient WAN optimization .....	972
Operating modes and VDOMs .....	972
WAN optimization tunnels .....	973
WAN optimization and user and device identity policies, load balancing and traffic shaping .....	974
WAN optimization and HA .....	975
WAN optimization, web caching and memory usage .....	975
WAN Optimization Configuration .....	975
Manual (peer-to-peer) and active-passive WAN optimization .....	975
WAN optimization profiles .....	978
Monitoring WAN optimization performance .....	980
WAN optimization configuration summary .....	981
Best practices .....	984
Example Basic manual (peer-to-peer) WAN optimization configuration .....	985
Example Active-passive WAN optimization .....	991
Example Adding secure tunneling to an active-passive WAN optimization configuration .....	999
Peers and authentication groups .....	1006
Basic WAN optimization peer requirements .....	1006
How FortiGate units process tunnel requests for peer authentication .....	1006
Configuring peers .....	1007
Configuring authentication groups .....	1008
Secure tunneling .....	1010
Monitoring WAN optimization peer performance .....	1011
Web Cache Concepts .....	1011
Turning on web caching for HTTP and HTTPS traffic .....	1011

Turning on web caching for HTTPS traffic.....	1012
Changing the ports on which to look for HTTP and HTTPS traffic to cache.....	1015
Web caching and HA.....	1015
Web caching and memory usage.....	1015
Changing web cache settings.....	1015
Web Cache Configuration.....	1018
Forwarding URLs to forwarding servers and exempting web sites from web caching..	1018
Monitoring Web caching performance.....	1020
Example Web caching of HTTP and HTTPS Internet content for users on an internal network.....	1020
Example reverse proxy web caching and SSL offloading for an Internet web server using a static one-to-one virtual IP.....	1023
Using a FortiCache as a cache service.....	1027
WCCP Concepts.....	1028
WCCP Configuration.....	1029
WCCP configuration overview.....	1029
WCCP service groups, service numbers, service IDs and well known services.....	1029
Example caching HTTP sessions on port 80 using WCCP.....	1033
Example caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP.....	1035
WCCP packet flow.....	1038
Configuring the forward and return methods and adding authentication.....	1038
WCCP Messages.....	1039
Troubleshooting WCCP.....	1039
Web Proxy Concepts.....	1040
Proxy Policy.....	1040
Proxy Authentication.....	1040
Proxy Addresses.....	1044
Web Proxy firewall services and service groups.....	1045
Learn client IP.....	1046
Web Proxy Configuration.....	1047
General web proxy configuration steps.....	1047
Policy Matching based on Referrer Headers and Query Strings.....	1051
Explicit Proxy Concepts.....	1053
The FortiGate explicit web proxy.....	1053
Other explicit web proxy options.....	1055
Proxy chaining (web proxy forwarding servers).....	1056
Security profiles, threat weight, device identification, and the explicit web proxy.....	1060
Explicit web proxy sessions and user limits.....	1060
Explicit Proxy Configuration.....	1062
Configuring an external IP address for the IPv4 explicit web proxy.....	1062
Configuring an external IP address for the IPv6 explicit web proxy.....	1062
Restricting the IP address of the IPv4 explicit web proxy.....	1062

Restricting the outgoing source IP address of the IPv4 explicit web proxy.....	1063
Restricting the IP address of the explicit IPv6 web proxy.....	1063
Restricting the outgoing source IP address of the IPv6 explicit web proxy.....	1063
Explicit proxy firewall address types.....	1063
Proxy auto-config (PAC) configuration.....	1064
Unknown HTTP version.....	1064
Authentication realm.....	1065
Implementing Botnet features.....	1065
Adding disclaimer messages to explicit proxy policies.....	1065
Changing HTTP headers.....	1065
Preventing the explicit web proxy from changing source addresses.....	1066
Kerberos and NTLM authentication.....	1071
Kerberos authentication for explicit proxy users.....	1071
Transparent Proxy Concepts.....	1081
More about the transparent proxy.....	1081
Transparent Proxy Configuration.....	1083
FTP Proxy Concepts.....	1086
The FortiGate explicit FTP proxy.....	1086
How to use the explicit FTP proxy to connect to an FTP server.....	1087
Security profiles, threat weight, device identification, and the explicit FTP proxy.....	1089
Explicit FTP proxy sessions and user limits.....	1090
FTP Proxy Configuration.....	1090
General explicit FTP proxy configuration steps.....	1090
Restricting the IP address of the explicit FTP proxy.....	1093
Restricting the outgoing source IP address of the explicit FTP proxy.....	1093
Example users on an internal network connecting to FTP servers on the Internet through the explicit FTP with RADIUS authentication and virus scanning.....	1093
Diagnose commands for WAN Optimization.....	1098
get test {wad   wccpd} <test_level>.....	1098
diagnose wad.....	1099
diagnose wacs.....	1102
diagnose wadbd.....	1103
diagnose debug application {wad   wccpd} [<debug_level>].....	1103
diagnose test application wad 2200.....	1103
<b>Chapter 8 - FortiView.....</b>	<b>1106</b>
Purpose.....	1107
What's new in FortiOS 5.6.....	1108
FortiOS 5.6.4.....	1108
FortiOS 5.6.3.....	1108
FortiOS 5.6.1.....	1108
FortiOS 5.6.0.....	1109
Overview.....	1111

Enabling FortiView.....	1112
FortiView Feature Support - Platform Matrix.....	1112
Configuration Dependencies.....	1116
FortiView interface.....	1118
FortiView consoles.....	1122
Sources.....	1123
Destinations.....	1124
Applications.....	1125
Cloud Applications.....	1126
Web Sites.....	1127
Threats.....	1128
WiFi Clients.....	1129
Traffic Shaping.....	1130
System Events.....	1131
VPN.....	1132
Endpoint Vulnerability.....	1133
Threat Map.....	1134
Policies.....	1135
Interfaces.....	1136
FortiSandbox.....	1137
All Sessions.....	1138
Reference.....	1139
Filtering options.....	1140
Drill-Down Options.....	1143
Columns displayed.....	1145
Risk level indicators.....	1151
Troubleshooting FortiView.....	1152
No logging data is displayed.....	1152
Logging is enabled, but data is not appearing.....	1152
<b>Chapter 9 - Fortinet Communication Ports and Protocols.....</b>	<b>1153</b>
Introduction.....	1153
What's new in FortiOS 5.6.....	1154
FortiOS 5.6.3.....	1154
FortiGate open ports.....	1155
FortiAnalyzer open ports.....	1158
FortiAP-S open ports.....	1160
FortiAuthenticator open ports.....	1162
FortiClient open ports.....	1165
FortiCloud open ports.....	1166
FortiDB open ports.....	1167
FortiGuard open ports.....	1168

<b>Chapter 10 - FortiWiFi and FortiAP Configuration Guide .....</b>	<b>1232</b>
What's new in FortiOS 5.6 .....	1233
FortiOS 5.6.4 .....	1233
FortiOS 5.6.3 .....	1233
FortiOS 5.6.1 .....	1239
FortiOS 5.6.0 .....	1241
Introduction to wireless networking .....	1250
Wireless concepts .....	1250
Security .....	1251
Authentication .....	1253
Wireless networking equipment .....	1253
Automatic Radio Resource Provisioning .....	1254
Captive portals .....	1256
Introduction to Captive portals .....	1256
Configuring a captive portal .....	1256
Customizing captive portal pages .....	1258
Configuration example - Captive portal WiFi access control .....	1264
Configuring a WiFi LAN .....	1267
Overview of WiFi controller configuration .....	1267
Setting your geographic location .....	1269
Creating a FortiAP Profile .....	1270
Defining a wireless network interface (SSID) .....	1272
Defining SSID Groups .....	1281
Dynamic user VLAN assignment .....	1281

Configuring user authentication .....	1285
Configuring firewall policies for the SSID .....	1287
Configuring the built-in access point on a FortiWiFi unit .....	1288
Access point deployment .....	1290
Overview .....	1290
Network topology for managed APs .....	1290
Discovering and authorizing APs .....	1293
Advanced WiFi controller discovery .....	1299
Wireless client load balancing for high-density deployments .....	1301
FortiAP Groups .....	1303
LAN port options .....	1303
Preventing IP fragmentation of packets in CAPWAP tunnels .....	1306
LED options .....	1307
CAPWAP bandwidth formula .....	1308
Wireless Mesh .....	1310
Overview of Wireless Mesh .....	1310
Configuring a meshed WiFi network .....	1314
Configuring a point-to-point bridge .....	1317
Hotspot 2.0 .....	1318
Combining WiFi and wired networks with a software switch .....	1323
Combining WiFi and wired networks with a software switch .....	1323
FortiAP local bridging (Private Cloud-Managed AP) .....	1325
Using bridged FortiAPs to increase scalability .....	1327
Using Remote WLAN FortiAPs .....	1329
Configuring the FortiGate for remote FortiAPs .....	1329
Configuring the FortiAP units .....	1331
Preauthorizing FortiAP units .....	1331
Features for high-density deployments .....	1332
Power save feature .....	1332
Broadcast packet suppression .....	1332
Multicast to unicast conversion .....	1333
Ignore weak or distant clients .....	1333
Turn off 802.11b protocol .....	1334
Disable low data rates .....	1334
Limit power .....	1334
Use frequency band load-balancing .....	1335
AP load balancing .....	1335
Application rate-limiting .....	1336
AP Group management and dynamic VLAN assignment .....	1336
Sharing Tunnel SSIDs within a single managed AP between VDOMs as a Virtual AP for multi-tenancy .....	1336
FortiAP LED Blinking .....	1337

Wireless controller optimization for large deployment - AP image upgrade.....	1337
Protecting the WiFi Network.....	1338
Wireless IDS.....	1338
WiFi data channel encryption.....	1339
Protected Management Frames and Opportunistic Key Caching support.....	1340
Bluetooth Low Energy (BLE) Scan.....	1340
Wireless network monitoring.....	1342
Monitoring wireless clients.....	1342
Monitoring rogue APs.....	1342
Suppressing rogue APs.....	1347
Monitoring wireless network health.....	1347
Configuring wireless network clients.....	1348
Windows XP client.....	1348
Windows 7 client.....	1353
Mac OS client.....	1357
Linux client.....	1359
Troubleshooting.....	1361
Wireless network examples.....	1364
Basic wireless network.....	1364
A more complex example.....	1369
Managing a FortiAP with FortiCloud.....	1379
FortiCloud-managed FortiAP WiFi.....	1379
FortiCloud-managed FortiAP WiFi without a key.....	1380
Using a FortiWiFi unit as a client.....	1382
Use of client mode.....	1382
Configuring client mode.....	1384
Support for location-based services.....	1386
Overview.....	1386
Configuring location tracking.....	1386
Viewing device location data on the FortiGate unit.....	1387
Troubleshooting.....	1389
FortiAP shell command through CAPWAP control tunnel.....	1389
Signal strength issues.....	1389
Throughput issues.....	1393
Connection issues.....	1394
General problems.....	1399
Packet sniffer.....	1402
Useful debugging commands.....	1406
Reference.....	1408
FortiAP web-based manager.....	1409
Wireless radio channels.....	1411
WiFi event types.....	1413

FortiAP CLI.....	1413
<b>Chapter 11 - Hardening.....</b>	<b>1420</b>
Building security into FortiOS.....	1420
Boot PROM and BIOS security.....	1420
FortiOS kernel and user processes.....	1420
Administration access security.....	1420
Network security.....	1422
FIPS and Common Criteria.....	1423
PSIRT advisories.....	1423
FortiOS ports and protocols.....	1424
FortiOS open ports.....	1424
Closing open ports.....	1427
Security best practices.....	1427
Install the FortiGate unit in a physically secure location.....	1427
Register your product with Fortinet Support.....	1427
Keep your FortiOS firmware up to date.....	1427
System administrator best practices.....	1428
Global commands for stronger and more secure encryption.....	1431
Disable sending Malware statistics to FortiGuard.....	1432
Disable auto USB installation.....	1432
Set system time by synchronizing with an NTP server.....	1433
Enable password policies.....	1433
Configure auditing and logging.....	1433
Disable interfaces that not used.....	1434
Disable unused protocols on interfaces.....	1434
Use local-in policies to close open ports or restrict access.....	1435
<b>Chapter 12 - Hardware Acceleration.....</b>	<b>1437</b>
Whats New in Hardware Acceleration for FortiOS 5.6.....	1437
Bandwidth control between the ISF and NP6 XAUI ports (437911).....	1437
SNMP/CLI monitoring capabilities of NP6 session table and session drift (441532)....	1437
NP6 Host Protection Engine (HPE) adds protection for DDoS attacks (363398).....	1438
Improved visibility of SPU and nTurbo hardware acceleration (389711).....	1440
NP4Lite option to disable offloading ICMP traffic in IPsec tunnels (383939).....	1440
NP6 IPv4 invalid checksum anomaly checking (387675).....	1440
Stripping clear text padding and IPsec session ESP padding (416950).....	1441
Optionally disable NP6 offloading of traffic passing between 10Gbps and 1Gbps interfaces (392436).....	1441
Hardware acceleration overview.....	1442
Content processors (CP4, CP5, CP6, CP8, and CP9).....	1442
Security processors (SPs).....	1445
Network processors (NP1, NP2, NP3, NP4, NP4Lite, NP6 and NP6Lite).....	1447
Enabling strict protocol header checking disables all hardware acceleration.....	1451

sFlow and NetFlow and hardware acceleration.....	1451
Checking that traffic is offloaded by NP processors.....	1451
Dedicated Management CPU.....	1453
Offloading flow-based content inspection with NTurbo and IPSA.....	1454
Preventing packet ordering problems with NP4, NP6 and NP6lite FortiGates under heavy load.....	1455
NP6 and NP6lite Acceleration.....	1456
NP6 session fast path requirements.....	1456
NP6Lite processors.....	1458
NP6 and NP6Lite processors and sFlow and NetFlow.....	1458
NP6 processors and traffic shaping.....	1458
NP Direct.....	1458
Viewing your FortiGate NP6 processor configuration.....	1459
Optimizing NP6 performance by distributing traffic to XAUI links.....	1460
Increasing NP6 offloading capacity using link aggregation groups (LAGs).....	1461
NP6 processors and redundant interfaces.....	1462
Configuring Inter-VDOM link acceleration with NP6 processors.....	1463
Disabling offloading IPsec Diffie-Hellman key exchange.....	1466
Configuring individual NP6 processors.....	1466
Enabling per-session accounting for offloaded NP6 or NP6lite sessions.....	1472
Configuring NP6 session timeouts.....	1473
Configure the number of IPsec engines NP6 processors use.....	1473
Stripping clear text padding and IPsec session ESP padding.....	1474
Disable NP6 CAPWAP offloading.....	1474
Optionally disable NP6 offloading of traffic passing between 10Gbps and 1Gbps interfaces.....	1474
Enabling bandwidth control between the ISF and NP6 XAUI ports.....	1475
NP6 session drift.....	1475
FortiGate NP6 architectures.....	1477
FortiGate-300D fast path architecture.....	1477
FortiGate-300E and 301E fast path architecture.....	1477
FortiGate-400D fast path architecture.....	1479
FortiGate-500D fast path architecture.....	1480
FortiGate-500E and 501E fast path architecture.....	1480
FortiGate-600D fast path architecture.....	1481
FortiGate-800D fast path architecture.....	1482
FortiGate-900D fast path architecture.....	1484
FortiGate-1000D fast path architecture.....	1486
FortiGate-1200D fast path architecture.....	1488
FortiGate-1500D fast path architecture.....	1491
FortiGate-1500DT fast path architecture.....	1492
FortiGate-2000E fast path architecture.....	1494

FortiGate-2500E fast path architecture.....	1496
FortiGate-3000D fast path architecture.....	1499
FortiGate-3100D fast path architecture.....	1500
FortiGate-3200D fast path architecture.....	1501
FortiGate-3700D fast path architecture.....	1504
FortiGate-3700DX fast path architecture.....	1508
FortiGate-3800D fast path architecture.....	1512
FortiGate-3810D fast path architecture.....	1514
FortiGate-3815D fast path architecture.....	1515
FortiGate-3960E fast path architecture.....	1517
FortiGate-3980E fast path architecture.....	1518
FortiGate-5001D fast path architecture.....	1520
FortiGate-5001E and 5001E1 fast path architecture.....	1522
FortiController-5902D fast path architecture.....	1524
FortiGate NP6lite architectures.....	1526
FortiGate-200E and 201E fast path architecture.....	1526
NP4 and NP4Lite Acceleration.....	1528
Viewing your FortiGate's NP4 configuration.....	1528
NP4 and NP4Lite processors and sFlow and NetFlow.....	1529
Configuring NP4 traffic offloading.....	1529
Increasing NP4 offloading capacity using link aggregation groups (LAGs).....	1531
NP4 traffic shaping offloading.....	1531
NP4 IPsec VPN offloading.....	1532
Configuring Inter-VDOM link acceleration with NP4 processors.....	1532
Offloading NP4 anomaly detection.....	1536
FortiGate NP4 architectures.....	1539
FortiGate-600C.....	1539
FortiGate-800C.....	1540
FortiGate-1000C.....	1541
FortiGate-1240B.....	1542
FortiGate-3040B.....	1543
FortiGate-3140B.....	1544
FortiGate-3140B — load balance mode.....	1545
FortiGate-3240C.....	1545
FortiGate-3600C.....	1547
FortiGate-3950B and FortiGate-3951B.....	1548
FortiGate-3950B and FortiGate-3951B — load balance mode.....	1550
FortiGate-5001C.....	1551
FortiGate-5001B.....	1552
Setting switch-mode mapping on the ADM-XD4.....	1553
Hardware acceleration get and diagnose commands.....	1553
get hardware npu np6.....	1553

diagnose npu np6 .....	1554
Using diagnose npu np6 npu-feature to verify enabled NP6 features .....	1555
Using the diagnose sys session/session6 list command .....	1556
diagnose npu np6 session-stats <np6-id> (number of NP6 IPv4 and IPv6 sessions) ..	1560
diagnose npu np6 ipsec-stats (NP6 IPsec statistics) .....	1561
diagnose sys mcast-session/session6 list (IPv4 and IPv6 multicast sessions) .....	1562
diagnose npu np6 sse-stats <np6-id> (number of NP6 sessions and dropped sessions) .....	1563
diagnose npu np6 dce <np6-id> (number of dropped NP6 packets) .....	1563
diagnose hardware deviceinfo nic <interfac-name> (number of packets dropped by an interface) .....	1564
dianose npu np6 synproxy-stats (NP6 SYN-proxied sessions and unacknowledged SYNs) .....	1565

## **Chapter 13 - High Availability.....1566**

FortiOS 5.6 HA new features .....	1566
Solving the high availability problem .....	1569
FortiGate Cluster Protocol (FGCP) .....	1569
FortiGate Session Life Support Protocol (FGSP) .....	1570
VRRP high availability .....	1571
Session-Aware Load Balancing Clustering (SLBC) .....	1572
Enhanced Load Balancing Clustering (ELBC) .....	1573
Content clustering .....	1573
An introduction to the FGCP .....	1575
About the FGCP .....	1575
Synchronizing the configuration (and settings that are not synchronized) .....	1578
Preparing the FortiGates before setting up an FGCP cluster .....	1579
Configuring FortiGates for FGCP HA operation .....	1580
Active-passive and active-active HA .....	1585
Identifying the cluster and cluster units .....	1586
Device failover, link failover, and session failover .....	1587
Primary unit selection .....	1587
HA override .....	1596
FortiGate HA compatibility with DHCP and PPPoE .....	1599
HA and distributed clustering .....	1600
Clusters of three or four FortiGates .....	1601
Disk storage configuration and HA .....	1605
FGCP high availability best practices .....	1606
FGCP HA terminology .....	1608
HA GUI options .....	1611
FGCP configuration examples and troubleshooting .....	1615
About the examples in this chapter .....	1615
How to set up FGCP clustering (recommended steps) .....	1615

Setting up two new FortiGates as an FGCP cluster.....	1622
Adding a new FortiGate to an operating cluster.....	1634
Active-active HA cluster in transparent mode.....	1635
FortiGate-5000 active-active HA cluster with FortiClient licenses.....	1646
Converting a standalone FortiGate to a cluster.....	1657
1. Setting up registration and licensing.....	1658
2. Configuring the primary FortiGate for HA.....	1658
3. Connecting the backup FortiGate.....	1659
4. Configuring the backup FortiGate for HA.....	1660
5. Viewing the status of the HA cluster.....	1661
6. Results.....	1663
7. (Optional) Upgrading the firmware for the HA cluster.....	1664
Replacing a failed cluster unit.....	1665
FGCP HA with 802.3ad aggregated interfaces.....	1667
Example HA and redundant interfaces.....	1678
Troubleshooting HA clusters.....	1689
Virtual clusters.....	1694
Virtual clustering overview.....	1694
Configuring virtual clustering.....	1696
Virtual clustering configuration examples.....	1700
Example inter-VDOM links in a virtual clustering configuration.....	1701
Troubleshooting virtual clustering.....	1703
Full mesh HA.....	1704
Full mesh HA overview.....	1704
Example full mesh HA configuration.....	1706
Troubleshooting full mesh HA.....	1716
Operating clusters and virtual clusters.....	1718
Operating a cluster.....	1718
Operating a virtual cluster.....	1718
Managing individual cluster units using a reserved out-of-band management interface.....	1719
Managing individual cluster units using an in-band management IP address.....	1725
Managing individual cluster units in a virtual cluster.....	1725
Shutting down or rebooting the primary unit.....	1726
The primary unit acts as a router for subordinate unit management traffic.....	1726
Cluster communication with RADIUS and LDAP servers.....	1727
Clusters and FortiGuard services.....	1727
Clusters and logging.....	1728
Clusters and SNMP.....	1731
Adding FortiClient licenses to a cluster.....	1734
Cluster members list.....	1736
Virtual cluster members list.....	1736

Viewing HA statistics.....	1737
Changing the HA configuration of an operating cluster.....	1737
Changing the HA configuration of an operating virtual cluster.....	1737
Changing the subordinate unit host name and device priority.....	1738
Upgrading cluster firmware.....	1738
Downgrading cluster firmware.....	1740
Backing up and restoring the cluster configuration.....	1741
Monitoring cluster units for failover.....	1741
Viewing cluster status from the CLI.....	1742
Managing individual cluster units.....	1749
Disconnecting a cluster unit from a cluster.....	1749
Adding a disconnected FortiGate back to its cluster.....	1750
diagnose sys ha dump-by command.....	1751
HA and failover protection.....	1753
About active-passive failover.....	1753
About active-active failover.....	1754
Device failover.....	1754
HA heartbeat and communication between cluster units.....	1755
Cluster virtual MAC addresses.....	1762
Synchronizing the configuration.....	1769
Synchronizing kernel routing tables.....	1777
Configuring graceful restart for dynamic routing failover.....	1779
Link failover (port monitoring or interface monitoring).....	1780
Monitoring VLAN interfaces.....	1786
Sub-second failover.....	1786
Remote link failover.....	1787
Failover and attached network equipment.....	1792
Monitoring cluster units for failover.....	1792
NAT/Route mode active-passive cluster packet flow.....	1792
Transparent mode active-passive cluster packet flow.....	1794
Failover performance.....	1797
Session failover (session-pickup).....	1799
Enabling session-pickup for TCP, UDP, ICMP, and multicast session failover.....	1799
If session pickup is disabled.....	1800
Improving session synchronization performance.....	1800
Session failover limitations for sessions passing through the cluster.....	1801
Session failover limitations for sessions terminated by the cluster.....	1804
Synchronizing IPsec VPN SAs.....	1806
WAN optimization and HA.....	1807
HA and load balancing.....	1808
Load balancing overview.....	1808
Selecting a load balancing schedule.....	1810

Load balancing TCP and UDP sessions.....	1811
Using NP4 or NP6 processors to offload load balancing.....	1811
Configuring weighted-round-robin weights.....	1811
Dynamically optimizing weighted load balancing according to how busy cluster units are.....	1812
Example weighted load balancing configuration.....	1814
NAT/Route mode active-active cluster packet flow.....	1816
Transparent mode active-active cluster packet flow.....	1819
HA with FortiGate-VM and third-party products.....	1823
FortiGate-VM for VMware HA configuration.....	1823
FortiGate VM for Hyper-V HA configuration.....	1823
Troubleshooting layer-2 switches.....	1824
Failover issues with layer-3 switches.....	1824
Failover and attached network equipment.....	1824
Ethertype conflicts with third-party switches.....	1825
LACP, 802.3ad aggregation and third-party switches.....	1825
VRRP high availability.....	1826
Configuring VRRP.....	1827
Adding a VRRP virtual router to a FortiGate interface.....	1827
Setting up VRRP failover.....	1828
Using VRRP virtual MAC addresses.....	1830
Setting up VRRP groups.....	1831
Example VRRP configuration: two FortiGates in a VRRP group.....	1831
Example VRRP configuration: VRRP load balancing two FortiGates and two VRRP groups.....	1833
Optional VRRP configuration settings.....	1834
FortiController-5000 support for VRRP HA.....	1834
FortiGate Session Life Support Protocol (FGSP).....	1835
Configuring FGSP HA cluster-sync instances.....	1837
Synchronizing TCP and SCTP sessions.....	1838
Synchronizing the configuration.....	1839
FGSP and firmware upgrades.....	1840
Backing up and restoring the configuration of an FGSP cluster.....	1841
IPsec tunnel synchronization.....	1841
Synchronizing UDP and ICMP (connectionless) sessions.....	1841
Synchronizing NAT sessions.....	1841
Synchronizing asymmetric sessions.....	1842
Synchronizing expectation sessions.....	1843
Security profile flow-based inspection and asymmetric traffic.....	1843
Notes and limitations.....	1843
Configuring session synchronization links.....	1844
Basic example configuration.....	1844

Verifying the FGSP configuration and synchronization.....	1847
<b>Chapter 14 - IPsec VPN.....</b>	<b>1849</b>
Introduction.....	1849
What's new in FortiOS 5.6.....	1851
FortiOS 5.6.4.....	1851
FortiOS 5.6.3.....	1851
FortiOS 5.6.1.....	1853
FortiOS 5.6.0.....	1856
IPsec VPN concepts.....	1861
VPN tunnels.....	1861
VPN gateways.....	1863
Clients, servers, and peers.....	1865
Encryption.....	1866
Authentication.....	1868
Phase 1 and Phase 2 settings.....	1868
Security Association.....	1869
IKE and IPsec packet processing.....	1870
IPsec VPN overview.....	1875
Types of VPNs.....	1875
Planning your VPN.....	1876
General preparation steps.....	1878
How to use this guide to configure an IPsec VPN.....	1878
IPsec VPN in the web-based manager.....	1879
Phase 1 configuration.....	1879
Phase 2 configuration.....	1886
Concentrator.....	1890
IPsec Monitor.....	1891
Phase 1 parameters.....	1892
Overview.....	1892
Defining the tunnel ends.....	1892
Choosing Main mode or Aggressive mode.....	1893
Choosing the IKE version.....	1893
Authenticating the FortiGate unit.....	1895
Authenticating remote peers and clients.....	1897
Defining IKE negotiation parameters.....	1903
Using XAuth authentication.....	1908
Dynamic IPsec route control.....	1909
Phase 2 parameters.....	1911
Phase 2 settings.....	1911
Configuring the Phase 2 parameters.....	1913
Defining VPN security policies.....	1917
Defining policy addresses.....	1917

Defining security policies for policy-based and route-based VPNs .....	1918
Gateway-to-gateway .....	1923
Configuration overview .....	1923
Gateway-to-gateway configuration .....	1925
How to work with overlapping subnets .....	1930
Testing .....	1935
Hub-and-spoke configurations .....	1938
Configuration overview .....	1938
Configure the hub .....	1940
Configure the spokes .....	1945
Dynamic spokes configuration example .....	1948
Dynamic DNS configuration .....	1955
Dynamic DNS over VPN concepts .....	1955
DDNS topology .....	1957
Configuration overview .....	1958
FortiClient dialup-client configuration .....	1968
Configuration overview .....	1968
FortiGate dialup-client configurations .....	1977
Configuration overview .....	1977
Supporting IKE Mode Config clients .....	1985
IKE Mode Config overview .....	1985
Automatic configuration overview .....	1985
IKE Mode Config method .....	1985
Internet-browsing configuration .....	1990
Configuration overview .....	1990
Routing all remote traffic through the VPN tunnel .....	1992
Redundant VPN configurations .....	1994
Configuration overview .....	1994
Transparent mode VPNs .....	1999
Configuration overview .....	1999
IPv6 IPsec VPNs .....	2004
Configuration examples .....	2005
L2TP and IPsec (Microsoft VPN) .....	2016
Overview .....	2016
Assumptions .....	2017
Configuration overview .....	2017
GRE over IPsec (Cisco VPN) .....	2025
Configuration overview .....	2026
Configuring the Cisco router .....	2031
Keep-alive support for GRE .....	2031
Protecting OSPF with IPsec .....	2033
Configuration overview .....	2033

Redundant OSPF routing over IPsec .....	2040
OSPF over dynamic IPsec .....	2044
BGP over dynamic IPsec .....	2047
IPsec Auto-Discovery VPN (ADVPN) .....	2051
Example ADVPN configuration .....	2052
Logging and monitoring .....	2057
Monitoring VPN connections .....	2057
VPN event logs .....	2058
Troubleshooting .....	2059
Common IPsec VPN problems .....	2059
Troubleshooting connection issues .....	2063
General troubleshooting tips .....	2067
Troubleshooting L2TP and IPsec .....	2068
Troubleshooting GRE over IPsec .....	2071
<b>Chapter 15 - IPv6 .....</b>	<b>2074</b>
Possible addresses: .....	2074
IPv6 packet structure .....	2075
Benefits of IPv6 .....	2075
What's new for IPv6 in FortiOS 5.6 .....	2075
IPv6 (5.6.3) .....	2075
IPv6 Features .....	2079
IPv6 policies .....	2079
IPv6 Network Address Translation .....	2087
ICMPv6 .....	2092
IPv6 in dynamic routing .....	2096
Dual stack routing .....	2097
IPv6 tunnelling .....	2097
SIP over IPv6 .....	2098
New Fortinet FortiGate IPv6 MIB fields .....	2099
IPv6 Per-IP traffic shaper .....	2100
DHCPv6 .....	2101
IPv6 forwarding .....	2102
Obtaining IPv6 addresses from an IPv6 DHCP server .....	2102
Authentication Support .....	2102
IPv6 Configuration .....	2104
IPv6 address groups .....	2104
IPv6 address ranges .....	2105
IPv6 firewall addresses .....	2105
ICMPv6 .....	2107
IPv6 IPsec VPN .....	2108
TCP MSS values .....	2121
BGP and IPv6 .....	2121

RIPng — RIP and IPv6.....	2122
IPv6 RSSO support.....	2128
IPv6 IPS.....	2128
Blocking IPv6 packets by extension headers.....	2128
IPv6 Denial of Service policies.....	2129
Configure hosts in an SNMP v1/2c community to send queries or receive traps.....	2129
IPv6 PIM sparse mode multicast routing.....	2129
<b>Chapter 16 - Logging and Reporting.....</b>	<b>2130</b>
What's new in FortiOS 5.6.....	2131
FortiOS 5.6.4.....	2131
FortiOS 5.6.3.....	2131
FortiOS 5.6.1.....	2133
FortiOS 5.6.0.....	2133
Logging and reporting overview.....	2135
What is logging?.....	2135
FortiOS features available for logging.....	2136
Log messages.....	2141
Log files and types.....	2147
Log database and datasets.....	2148
Log devices.....	2150
Reports.....	2154
Best Practices: Log management.....	2155
Logging and reporting for small networks.....	2157
Modifying default log device settings.....	2157
Configuring the backup solution.....	2159
Logging and reporting for large networks.....	2161
Modifying default log device settings.....	2161
Configuring the backup solution.....	2163
Advanced logging.....	2166
Log backup and restore tools.....	2166
Configuring logging to multiple Syslog servers.....	2166
Using Automatic Discovery to connect to a FortiAnalyzer unit.....	2167
Activating a FortiCloud account for logging purposes.....	2168
Viewing log storage space.....	2168
Customizing and filtering log messages.....	2169
Viewing logs from the CLI.....	2169
Configuring NAC quarantine logging.....	2170
Logging local-in policies.....	2170
Tracking specific search phrases in reports.....	2172
Troubleshooting and logging.....	2174
Using log messages to help in troubleshooting issues.....	2174
Connection issues between FortiGate unit and logging devices.....	2175

Log database issues.....	2175
Logging daemon (Miglogd).....	2177
<b>Chapter 17 - Managing Devices.....</b>	<b>2178</b>
What's New in FortiOS 5.6.....	2178
FortiOS 5.6.1.....	2178
Managing “bring your own device”.....	2179
Device monitoring.....	2179
Device Groups.....	2180
Controlling access with a MAC Address Access Control List.....	2181
Security policies for devices.....	2182
<b>Chapter 18 - Managing a FortiSwitch with a FortiGate.....</b>	<b>2186</b>
Introduction.....	2186
Supported models.....	2186
Before you begin.....	2187
What's new for managed FortiSwitches in FortiOS 5.6.3 with FortiSwitch 3.6.3 (and later releases).....	2188
What's new for managed FortiSwitches in FortiOS 5.6.1 with FortiSwitch 3.6.0 (and later releases).....	2190
What's new for managed FortiSwitches in FortiOS 5.6 with FortiSwitch 3.6.0 (and later releases).....	2197
What's new for managed FortiSwitches in FortiOS 5.6 with FortiSwitch 3.5.4 (and later releases).....	2199
Before you begin.....	2205
How this guide is organized.....	2205
Connecting FortiLink ports.....	2206
1. Enable the switch controller on FortiGate.....	2206
2. Connect the FortiSwitch and FortiGate.....	2206
FortiLink configuration using the FortiGate GUI.....	2208
Summary of the procedure.....	2208
FortiLink split interface.....	2209
Authorizing the FortiSwitch.....	2209
Adding preauthorized FortiSwitches.....	2209
Managed FortiSwitch display.....	2210
Edit a managed FortiSwitch.....	2210
Network interface display.....	2211
Add link aggregation groups (Trunks).....	2211
Configure DHCP blocking, IGMP snooping, STP, and loop guard on managed FortiSwitch ports.....	2211
FortiLink configuration using the FortiGate CLI.....	2213
Summary of the procedure.....	2213
Configure FortiLink as a single link.....	2213
Configure FortiLink as a logical interface.....	2214
Network topologies for managed FortiSwitches.....	2215

Supported topologies .....	2215
Single FortiGate managing a single FortiSwitch .....	2215
Single FortiGate managing a stack of several FortiSwitches .....	2216
HA-mode FortiGates managing a single FortiSwitch .....	2216
HA-mode FortiGates managing a stack of several FortiSwitches .....	2217
HA-mode FortiGates managing a FortiSwitch two-tier topology .....	2217
Single FortiGate managing multiple FortiSwitches (using a hardware or software switch interface) .....	2218
HA-mode FortiGates managing two-tier FortiSwitches with access rings .....	2219
Dual-homed servers connected to FortiLink tier-1 FortiSwitches using an MCLAG ..	2220
Standalone FortiGate with dual-homed FortiSwitch access .....	2220
HA-mode FortiGates with dual-homed FortiSwitch access .....	2221
Grouping FortiSwitches .....	2221
Transitioning from a FortiLink split interface to a FortiLink MCLAG .....	2225
Optional setup tasks .....	2227
Configuring the FortiSwitch management port .....	2227
Converting to FortiSwitch standalone mode .....	2227
Changing the admin password on the FortiGate for all managed FortiSwitches ..	2228
FortiSwitch port features .....	2230
FortiSwitch ports display .....	2230
Configuring ports using the GUI .....	2231
Configuring ports using the FortiGate CLI .....	2231
FortiSwitch port security policy .....	2239
Configure the 802.1X settings for a virtual domain .....	2239
Override the virtual domain settings .....	2240
Define an 802.1X security policy .....	2241
Apply an 802.1X security policy to a FortiSwitch port .....	2242
Additional capabilities .....	2244
Execute custom FortiSwitch commands .....	2244
Firmware upgrade management and compatible version information .....	2245
FortiSwitch log export .....	2245
FortiSwitch per-port device visibility .....	2246
FortiGate CLI support for FortiSwitch features (on non-FortiLink ports) ..	2246
Troubleshooting .....	2252
Troubleshooting FortiLink issues .....	2252
<b>Chapter 19 - Networking .....</b>	<b>2254</b>
About this guide .....	2254
What's new in Networking .....	2254
FortiOS version 5.6.4 .....	2255
FortiOS version 5.6.3 .....	2255
FortiOS version 5.6.2 .....	2255
FortiOS version 5.6.1 .....	2256

FortiOS version 5.6.....	2256
Interfaces.....	2259
Administrative access.....	2259
Aggregate interfaces.....	2260
DHCP addressing mode on an interface.....	2261
DHCP servers and relays.....	2262
Interface MTU packet size.....	2269
Interface settings.....	2270
Loopback interfaces.....	2275
One-armed sniffer.....	2276
Physical ports.....	2279
PPPoE addressing mode on an interface.....	2280
Probing interfaces.....	2282
Redundant interfaces.....	2283
Dual Internet connections.....	2283
Secondary IP addresses to an interface.....	2286
Software switch.....	2286
Soft switch example.....	2287
Virtual switch.....	2288
Zones.....	2291
Virtual domains.....	2292
Wireless.....	2293
VLANs.....	2293
Botnet and command-and-control protection.....	2307
DNS.....	2307
DNS settings.....	2308
Additional DNS CLI configuration.....	2308
DDNS.....	2308
DNS servers.....	2310
Advanced static routing.....	2315
Routing concepts.....	2315
Static routing tips.....	2330
Policy routing.....	2331
Transparent mode static routing.....	2335
Static routing example.....	2336
Dynamic routing overview.....	2346
What is dynamic routing?.....	2346
Comparison of dynamic routing protocols.....	2349
Choosing a routing protocol.....	2354
Dynamic routing terminology.....	2355
Controlling how routing changes affect active sessions.....	2360
IPv6 in dynamic routing.....	2361

RIP.....	2362
RIP background and concepts.....	2362
Troubleshooting RIP.....	2373
Simple RIP example.....	2378
RIPng: RIP and IPv6.....	2393
OSPF.....	2400
OSPF background and concepts.....	2400
Troubleshooting OSPF.....	2412
Basic OSPF example.....	2414
Advanced inter-area OSPF example.....	2426
Controlling redundant links by cost.....	2437
BGP.....	2441
BGP background and concepts.....	2441
Troubleshooting BGP.....	2455
Dual-homed BGP example.....	2459
Redistributing and blocking routes in BGP.....	2472
IS-IS.....	2480
IS-IS background and concepts.....	2480
How IS-IS works.....	2480
Troubleshooting IS-IS.....	2486
Simple IS-IS example.....	2488
Network layout and assumptions.....	2489
Expectations.....	2490
CLI configuration.....	2490
Verification.....	2492
Troubleshooting.....	2495
Multicast forwarding.....	2496
Sparse mode.....	2496
Dense mode.....	2497
PIM support.....	2498
Multicast forwarding and FortiGate units.....	2499
Configuring FortiGate multicast forwarding.....	2500
Multicast routing examples.....	2503
Troubleshooting.....	2527
Netflow support.....	2527
sFlow support.....	2528
Packet capture.....	2529
<b>Chapter 20 - Parallel Path Processing - Life of a Packet.....</b>	<b>2531</b>
Parallel Path Processing.....	2532
High-level list of processes that affect packets.....	2533
Packet flow ingress and egress: FortiGates without network processor offloading.....	2534
Ingress.....	2534

Admission control .....	2535
Kernel .....	2535
UTM/NGFW .....	2537
Content processors (CP8 and CP9) .....	2537
Kernel .....	2538
Egress .....	2538
Packet flow: FortiGates with NP6 processors first packet of a new session .....	2539
Network processors (NP6) .....	2539
Packet flow: FortiGates with NP6 processors - packets in an offloaded session .....	2540
Packet flow: FortiGates with NP6 processors - packets in an NTurbo session .....	2541
UTM/NGFW packet flow: flow-based inspection .....	2543
UTM/NGFW packet flow: proxy-based inspection .....	2545
UTM/NGFW packet flow: explicit web proxy .....	2547
Comparison of inspection types .....	2549
Mapping security functions to inspection types .....	2549
More information about inspection methods .....	2549
<b>Chapter 21 - Sandbox Inspection .....</b>	<b>2551</b>
What's new in FortiOS 5.6 .....	2551
FortiOS 5.6.1 .....	2551
An Overview of Sandbox Inspection .....	2553
What is Sandbox Inspection? .....	2553
FortiSandbox Appliance vs FortiSandbox Cloud .....	2553
Sending Files for Sandbox Inspection .....	2554
Using FortiSandbox with a FortiGate .....	2555
Connecting a FortiGate to FortiSandbox .....	2555
FortiSandbox Console .....	2556
Sandbox Integration .....	2557
Overview .....	2557
Example Configuration .....	2558
Sandbox Inspection FAQ .....	2561
<b>Chapter 22 - Fortinet Security Fabric .....</b>	<b>2562</b>
About this guide .....	2562
What's new in the Security Fabric .....	2563
FortiOS version 5.6.2 .....	2563
FortiOS version 5.6.1 .....	2563
FortiOS version 5.6 .....	2564
Security Fabric overview .....	2566
Access security .....	2567
Client security .....	2567
Application security .....	2567
Cloud security .....	2568
NOC and SOC security .....	2568

Advanced threat intelligence.....	2568
Partner API.....	2569
The Security Fabric solution components.....	2570
Devices in the Security Fabric.....	2570
Security Fabric topology views.....	2573
Security Fabric Audit.....	2574
FortiTelemetry.....	2574
Configuring the Security Fabric.....	2575
System requirements.....	2575
Prerequisites.....	2575
Forming the Security Fabric.....	2576
Setting up data collection for the Security Fabric.....	2577
Using the Security Fabric to improve network security.....	2579
Understanding the Security Fabric dashboard widgets.....	2579
Viewing the Security Fabric topology.....	2580
Running a Security Fabric Audit.....	2582
Viewing monitoring information for devices in the Security Fabric.....	2585
Related resources.....	2586
<b>Chapter 23 - Security Profiles.....</b>	<b>2587</b>
What's new in FortiOS 5.6.....	2588
FortiOS 5.6.4.....	2588
FortiOS 5.6.3.....	2588
FortiOS 5.6.1.....	2589
FortiOS 5.6.0.....	2590
New FortiGuard Web Filter categories (407574).....	2595
Inside FortiOS: AntiVirus.....	2601
Advanced Protection against Malware and APTs.....	2601
Features.....	2601
Inside FortiOS: Application Control.....	2604
Enhance Control and Network Visibility.....	2604
Features.....	2605
Recipes.....	2608
Inside FortiOS: Intrusion Prevention System (IPS).....	2608
World Class Next Generation IPS Capabilities.....	2608
Features.....	2609
Inside FortiOS: Web Filtering.....	2612
Intelligent and Effective Content Control.....	2612
Features.....	2613
Security Profiles overview.....	2617
Traffic inspection.....	2617
Content inspection and filtering.....	2619
Security Profiles components.....	2622

Security Profiles/lists/sensors.....	2624
Inspection Modes.....	2624
Proxy-based inspection.....	2625
Flow-based inspection.....	2625
Changing between proxy and flow mode.....	2625
Comparison of inspection types.....	2627
Individual Security Profile considerations.....	2628
Proxy mode and flow mode antivirus and web filter profile options.....	2628
AntiVirus.....	2633
Antivirus concepts.....	2633
Enabling AntiVirus scanning.....	2645
Testing your antivirus configuration.....	2648
Example scenarios.....	2648
Web filter.....	2654
Web filter concepts.....	2654
Inspection Modes.....	2656
FortiGuard Web Filtering Service.....	2657
Configuring Web Filter Profiles.....	2663
Overriding FortiGuard website categorization.....	2668
Using cookies to authenticate users in a Web Filter override.....	2675
Web Profile Overrides.....	2675
SafeSearch.....	2676
YouTube Education Filter.....	2677
Static URL Filter.....	2678
Web content filter.....	2683
Web filtering example.....	2686
Advanced web filter configurations.....	2689
DNS Filter.....	2694
Application Control.....	2698
Application control concepts.....	2698
Cloud Access Security Inspection (CASI).....	2699
Enabling application control in profile-based modes.....	2699
Application Control actions.....	2703
Application considerations.....	2703
Application control monitor.....	2704
Application control examples.....	2704
Intrusion prevention.....	2709
IPS concepts.....	2709
Enabling IPS scanning.....	2712
IPS processing in an HA cluster.....	2715
Configure IPS options.....	2715
Enabling IPS packet logging.....	2719

Other IPS examples .....	2720
Anti-Spam filter.....	2727
Anti-Spam concepts.....	2727
Anti-Spam techniques.....	2727
Configuring Anti-Spam.....	2731
Order of spam filtering.....	2733
Spam actions.....	2734
Anti-Spam examples.....	2735
Data leak prevention.....	2737
Data leak prevention concepts.....	2737
Enable data leak prevention.....	2742
Creating/editing a DLP sensor.....	2743
DLP archiving.....	2745
DLP examples.....	2746
ICAP support.....	2751
The protocol.....	2751
Offloading using ICAP.....	2752
Configuring ICAP.....	2752
Example ICAP sequence.....	2753
Example ICAP scenario.....	2753
FortiClient Profiles.....	2755
Endpoint protection overview.....	2755
Configuring endpoint protection.....	2757
Configuring endpoint registration over a VPN.....	2760
Modifying the endpoint protection replacement messages.....	2762
Monitoring endpoints.....	2762
Proxy Options.....	2762
The use of different proxy profiles and profile options.....	2763
Proxy Options profile components.....	2763
SSL/SSH Inspection.....	2765
SSL inspection.....	2765
Why use SSL inspection.....	2769
SSL certificate inspection.....	2770
Creating or editing an SSL/SSH Inspection profile.....	2771
Secure white list database.....	2772
SSL server table for SSL offloading.....	2773
Custom Application & IPS Signatures.....	2774
Creating a custom IPS signature.....	2774
Custom signature syntax.....	2774
Custom signature keywords.....	2775
Creating a custom signature to block access to example.com.....	2787
Creating a custom signature to block the SMTP “vrfy” command.....	2789

Creating a custom signature to block files according to the file's hash value.....	2790
Other Security Profiles considerations.....	2792
Security Profiles and Virtual domains (VDOMs).....	2792
Conserve mode.....	2792
Using wildcards and Perl regular expressions.....	2794
Adding External Security Devices.....	2796
CPU allocation and tuning commands to survive reboot.....	2796
Excluding industrial IP signatures.....	2797
<b>Chapter 24 - Server Load Balancing.....</b>	<b>2798</b>
What's new for server load balancing in FortiOS 5.6.1.....	2798
Add server load balancing real servers on the Virtual Server GUI page (416709).....	2798
What's new for server load balancing in FortiOS 5.6.....	2799
IPv6, 6to4, and 4to6 server load balancing (280073).....	2799
Improved Server load balancing GUI pages (404169).....	2800
Inside FortiOS: Server Load Balancing.....	2800
Server Load Balancing combined with NGFW and UTM protection.....	2800
SSL/TLS offloading.....	2801
SSL/TLS content inspection.....	2801
Health Check.....	2801
Server Monitoring and Management.....	2802
HTTP Multiplexing.....	2802
Basic load balancing configuration example.....	2802
Configuring load balancing.....	2807
Load balancing and other FortiOS features.....	2809
Configuring load balancing from the GUI.....	2809
Configuring load balancing from the CLI.....	2811
Load balancing methods.....	2812
Session persistence.....	2813
Real servers.....	2813
Health check monitoring.....	2815
Load balancing limitations.....	2817
Monitoring load balancing.....	2818
Load balancing diagnose commands.....	2819
HTTP and HTTPS load balancing, multiplexing, and persistence.....	2820
HTTP and HTTPS multiplexing.....	2821
HTTP and HTTPS persistence.....	2821
HTTP host-based load balancing.....	2823
SSL/TLS load balancing.....	2825
SSL/TLS offloading.....	2825
Separate virtual-server client and server TLS version and cipher configuration.....	2827
Setting the SSL/TLS versions to use for server and client connections.....	2827
Setting the SSL/TLS cipher choices for server and client connections.....	2828

Protection from TLS protocol downgrade attacks.....	2829
Setting 3072- and 4096-bit Diffie-Hellman values.....	2829
Additional SSL load balancing and SSL offloading options.....	2829
SSL offloading support for Internet Explorer 6.....	2830
Selecting the cipher suites available for SSL load balancing.....	2831
Disabling SSL/TLS re-negotiation.....	2831
IP, TCP, and UDP load balancing.....	2835
Example HTTP load balancing to three real web servers.....	2835
GUI configuration.....	2836
CLI configuration.....	2839
Example Basic IP load balancing configuration.....	2840
Example Adding a server load balance port forwarding virtual IP.....	2841
Example Weighted load balancing configuration.....	2842
GUI configuration.....	2842
CLI configuration.....	2844
Example HTTP and HTTPS persistence configuration.....	2845
CLI configuration: adding persistence for a specific domain.....	2848
<b>Chapter 25 - SSL VPN.....</b>	<b>2850</b>
What's new in FortiOS 5.6.....	2851
FortiOS 5.6.4.....	2851
FortiOS 5.6.3.....	2851
FortiOS 5.6.1.....	2851
FortiOS 5.6.0.....	2853
Overview.....	2856
SSL VPN modes of operation.....	2857
Port forwarding mode.....	2858
SSL VPN conserve mode.....	2860
Traveling and security.....	2861
SSL VPN and IPv6.....	2861
Basic configuration.....	2862
User accounts and groups.....	2862
Configuring SSL VPN web portals.....	2867
Configuring security policies.....	2876
Configuring encryption key algorithms.....	2881
Additional configuration options.....	2882
The SSL VPN client.....	2892
FortiClient.....	2892
Tunnel mode client configuration.....	2892
The SSL VPN web portal.....	2894
Connecting to the FortiGate unit.....	2894
Web portal overview.....	2894
Portal configuration.....	2895

Using the Bookmarks widget .....	2899
Using the Quick Connection Tool .....	2902
Using FortiClient .....	2905
Setup examples .....	2906
Secure Internet browsing .....	2906
Split Tunnel .....	2908
Multiple user groups with different access permissions .....	2911
Client device certificate authentication with multiple groups .....	2916
Troubleshooting .....	2917
<b>Chapter 26 - System Administration .....</b>	<b>2920</b>
What's New in FortiOS 5.6 .....	2921
FortiOS 5.6.3 .....	2921
FortiOS 5.6.1 .....	2921
FortiOS 5.6 .....	2922
Administrators .....	2926
Administrator profiles .....	2926
Adding a local administrator .....	2927
LDAP authentication for administrators .....	2928
Other methods of administrator authentication .....	2929
Administrator lockout .....	2930
Monitoring administrators .....	2931
Management access .....	2931
Security precautions .....	2932
Central management .....	2935
Adding a FortiGate to FortiManager .....	2935
Configuration updates through FortiManager .....	2937
FortiGuard .....	2938
Firmware updates .....	2946
Administrative domains .....	2947
Backup and restore configurations .....	2947
Monitoring .....	2948
Dashboard .....	2948
sFlow support .....	2955
Monitor menus .....	2957
Logging .....	2957
Alert email .....	2958
SNMP .....	2959
SNMP get command syntax .....	2967
Replacement messages .....	2968
Administration for schools .....	2973
PPTP and L2TP .....	2976
How PPTP VPNs work .....	2976

FortiGate unit as a PPTP server.....	2978
Configuring the FortiGate unit for PPTP VPN.....	2981
Configuring the FortiGate unit for PPTP passthrough.....	2981
Testing PPTP VPN connections.....	2983
Logging VPN events.....	2983
Configuring L2TP VPNs.....	2984
L2TP configuration overview.....	2986
Session helpers.....	2990
Viewing the session helper configuration.....	2991
Changing the session helper configuration.....	2991
DCE-RPC session helper (dcerpc).....	2994
DNS session helpers (dns-tcp and dns-udp).....	2994
File transfer protocol (FTP) session helper (ftp).....	2994
H.323 and RAS session helpers (h323 and ras).....	2995
Media Gateway Controller Protocol (MGCP) session helper (mgcp).....	2995
ONC-RPC portmapper session helper (pmap).....	2996
PPTP session helper for PPTP traffic (pptp).....	2996
Remote shell session helper (rsh).....	2997
Real-Time Streaming Protocol (RTSP) session helper (rtsp).....	2997
Session Initiation Protocol (SIP) session helper (sip).....	2998
Trivial File Transfer Protocol (TFTP) session helper (tftp).....	2998
Oracle TNS listener session helper (tns).....	2998
Advanced concepts.....	2999
Single firewall vs. multiple virtual domains.....	2999
Modem.....	3001
Assigning IP address by MAC address.....	3004
IP addresses for self-originated traffic.....	3005
Disk.....	3005
CLI Scripts.....	3006
Rejecting PING requests.....	3007
Opening TCP 113.....	3008
Obfuscate HTTP responses from SSL VPN.....	3008
Blocking land attacks in Transparent mode.....	3008
<b>Chapter 27 - Traffic Shaping.....</b>	<b>3010</b>
What's new in FortiOS 5.6.....	3011
FortiOS 5.6.3.....	3011
The purpose of traffic shaping.....	3012
Quality of Service.....	3012
Traffic policing.....	3013
Bandwidth guarantee, limit, and priority interactions.....	3014
FortiGate traffic.....	3014
Through traffic.....	3015

Important considerations.....	3019
Traffic shaping methods.....	3022
Traffic shaping options.....	3022
Shared policy shaping.....	3023
Per-IP shaping.....	3028
Application control shaping.....	3031
Reverse direction traffic shaping.....	3033
Enabling traffic shaping in the security policy.....	3034
Scheduling Traffic Shaping Policies.....	3034
Type of Service priority.....	3035
Differentiated Services.....	3036
DSCP examples.....	3037
ToS and DSCP traffic mapping.....	3041
Traffic Shaper Monitor.....	3042
Examples.....	3044
QoS using priority from security policies.....	3044
QoS using priority from ToS or differentiated services.....	3048
Example setup for VoIP.....	3049
Troubleshooting traffic shaping.....	3055
Interface diagnosis.....	3055
Shaper diagnose commands.....	3055
Packet lost with the debug flow.....	3057
Session list details with dual traffic shaper.....	3057
Additional Information.....	3057
<b>Chapter 28 - Transparent Mode.....</b>	<b>3059</b>
What's new in FortiOS 5.6.....	3060
Using the Management IP address to populate pac-file-url.....	3060
Introduction to Transparent Mode.....	3061
What is Transparent Mode?.....	3061
Transparent Mode Features.....	3061
Transparent Mode Installation.....	3063
Installing a FortiGate in Transparent mode.....	3063
Using a Virtual Wire Pair to Simplify Transparent Mode.....	3064
Management IP configuration.....	3065
Networking in Transparent Mode.....	3067
Packet Forwarding.....	3067
Network Address Translation (NAT).....	3072
VLANs and Forwarding Domains.....	3073
Inter-VDOM links between NAT/Route and Transparent VDOMs.....	3077

## What's New for FortiOS 5.6.4

This section lists new features added to FortiOS 5.6.4 with links to the FortiOS Handbook for more information. FortiOS Handbook chapters will be updated for 5.6.4 only to document new features or to publish corrections or improvements to the content.

### Authentication

- [Authentication binds to MAC address on page 377](#)
- [New RADIUS accounting start message options, see RADIUS accounting start message options on page 389](#)
- [IPv6 TACACS+ server IP address on page 402](#)
- [Login credentials for guest users shown in clear text on GUI and voucher on page 424](#)

### Firewall

- [Using a FortiCache as a cache service on page 1027](#)

### FortiView

- [Increased visibility of interactivity in FortiView on page 1108](#)
- [Automatic synchronization of log display location on page 1108](#)

### FortiWiFi and FortiAP

- [FortiAP LED Blinking on page 1337](#)
- [Wireless controller optimization for large deployment - AP image upgrade on page 1337](#)

### Hardware acceleration

- [Per-session accounting is supported for FortiGates with NP6lite processors, Enabling per-session accounting for offloaded NP6 or NP6lite sessions on page 1472](#)

### High availability

- [FGSP configuration synchronization changes, see Synchronizing the configuration on page 1839](#)
- [Changes to get system status ha command output, see Viewing cluster status from the CLI on page 1742](#)

### IPsec VPN

- [Updates to IPsec VPN Wizard options on page 1862](#)

### Logging and reporting

- [Automatic synchronization of log display location on page 2131](#)

## Security profiles

- [Configuring the FortiClient offline grace period on page 2760](#)
- [Excluding industrial IP signatures on page 2797](#)

## SSL VPN

- [Changes to Tunnel Mode Client Options logic on page 2871](#)
- [Changes to HTTP header information on page 2919](#)

## Virtual FortiOS

- [SDN connector addressing on page 3256](#)
- [Support for KVM-based hypervisor in AWS on page 3257](#)
- [HA support for GCP on page 3260](#)
- [Other Virtual FortiOS Products on page 3254](#)

## What's New in previous versions of FortiOS 5.6

This chapter briefly highlights some of the higher profile new FortiOS 5.6 features, some of which have been enhanced for FortiOS 5.6.1 and FortiOS 5.6.3.

### FortiGate VM enhancements for AWS, Azure, Google, SDN connectors and more

The realm of virtual computing has become mainstream and not only does this mean that security appliances can also be virtual, there is also a requirement for security appliances in a virtual environment. These environments can be the publicly available platforms such as Amazon Web Services, Azure and Google Cloud Platform or they can be Software Defined Networks (SDN) such as those made by Cisco, HP, Nuage and OpenStack. For that reason, not only is the number of Virtual FortiOS variations growing along with what they can do, a number of the new features being introduced deal with integrating FortiOS into these environments. See [FortiGate VM enhancements for AWS, Azure, Google, SDN connectors and more \(5.6.3\) on page 181](#).

Recipes are now being also published for the cloud-based and SDN environments on the Fortinet Cookbook website.

- <http://cookbook.fortinet.com/amazon-web-services-aws/>
- <http://cookbook.fortinet.com/cisco-aci/>
- <http://cookbook.fortinet.com/microsoft-azure/>
- <http://cookbook.fortinet.com/nuage-vsp/>

### Fortinet Security Fabric enhancements

Security Fabric features and functionality continue to evolve. New features include improved performance and integration, a security audit function that finds possible problems with your network and recommends solutions, security fabric dashboard widgets, improved device detection, and the remote login to other FortiGates on the fabric. See [New Fortinet Security Fabric features on page 57](#).

### Security Fabric Audit

The Security Fabric Audit allows you to analyze your Security Fabric deployment to identify potential vulnerabilities and highlight best practices that could be used to improve your network's overall security and performance. See [Security Fabric Audit and Fabric Score on page 68](#).

### Re-designed Dashboard

The Dashboard has been enhanced to show more information with greater flexibility and more functionality. See [New Dashboard Features on page 74](#) for details.

### NGFW Policy Mode

You can operate your FortiGate in NGFW policy mode to simplify applying Application control and Web Filtering to firewall traffic. See [NGFW Policy Mode \(397035\) on page 91](#).

Flow-based inspection with profile-based NGFW mode is the default inspection mode in FortiOS 5.6.

## Transparent web proxy

In addition to the Explicit Web Proxy, FortiOS now supports a Transparent web proxy. You can use the transparent proxy to apply web authentication to HTTP traffic accepted by a firewall policy. See [Transparent web proxy \(386474\)](#) on page 83.

## Controlled failover between wireless controllers

Administrators can now define the role of the primary and secondary controllers on the FortiAP unit, allowing the unit to decide the order in which the FortiAP selects a FortiGate unit and how the FortiAP unit fails over to a backup FortiGate unit if the primary FortiGate Fails. See [Controlled failover between wireless controllers on page 99](#).

## FortiView Endpoint Vulnerability chart

A new FortiView chart that tracks vulnerability events detected by the FortiClients running on all devices registered with the FortiGate. See [New FortiView Endpoint Vulnerability Scanner chart \(378647\)](#) on page 94.

## FortiClient Profile changes

FortiClient profiles have been re-organized and now use the FortiGate to warn or quarantine endpoints that are not compliant with a FortiClient profile. See [FortiClient Profile changes \(386267, 375049\)](#).

## Adding Internet services to firewall policies

Internet service objects can be added to firewall policies instead of destination addresses and services. See [Adding Internet services to firewall policies \(389951\)](#).

## Source and destination NAT in a single Firewall policy

Extensions to VIPs support more NAT options and other enhancements. See [Combining source and destination NAT in the same policy \(388718\)](#).

## Other highlights

- Application Control is now standard with FortiCare support
- Real time logging to FortiAnalyzer and FortiCloud
- Multiple PSK for WPA Personal (393320)
- VXLAN support (289354)
- NP6 Host Protection Engine (HPE) adds protection for DDoS attacks (363398)
- FortiGate Logs can be sent to syslog servers in Common Event Format (CEF) (300128)
- New PPPoE features

## New Fortinet Security Fabric features

In FortiOS 5.6, the Security Fabric (previously known as the Cooperative Security Fabric) has been expanded in several ways to add more functionality and visibility.

One of the most important functional changes is that FortiAnalyzer is now a required part of the Security Fabric configuration. Also, two important new features, Security Fabric Audit and Fabric Score, have been added to provide a method to continually monitor and improve the Security Fabric configuration.

Many changes have been made through FortiView to improve the visibility of the Security Fabric. More information is now displayed and you can access downstream FortiGates directly from the root FortiGate's FortiView display.

Other smaller improvements have been made throughout the Security Fabric, with a focus on improving communication between devices.

In FortiOS 5.6.1, the new updated GUI design consolidates the Security Fabric features together under a new menu and has many new topological changes to provide greater visibility into the connectivity of your networked devices. This includes adding more Fortinet products to the topology and widgets. Other topology improvements include enhanced IPsec VPN detection (which now includes detection of downstream FortiGates) and support for SD-WAN. Smaller changes have also been made to add more information to device tooltip alerts in the Physical and Logical Topology views.

### Setting up the Fortinet Security Fabric in FortiOS 5.6

See the following FortiGate Cookbook recipes to get started in setting up the Security Fabric in FortiOS 5.6:

- [Installing a FortiGate in NAT/Route mode](#)
- [Security Fabric installation](#)

### Security Fabric between remote networks by enabling FortiTelemetry for IPsec VPN interfaces

You can now enable FortiTelemetry for IPsec VPN interfaces. The Security Fabric can now detect the downstream FortiGate through the IPsec VPN interface. This allows you to send FortiTelemetry communication over a Gateway-to-Gateway IPsec VPN tunnel between two remote networks. One of the networks would contain the root FortiGate and the network at the other end of the IPsec VPN tunnel can connect to the root FortiGate's Security Fabric.

#### In the GUI, to enable FortiTelemetry

1. Go to **Network > Interfaces** and edit your IPsec VPN interface.
2. Under Administrative Access enable FortiTelemetry.

**Edit Interface**

Interface Name: VPN-to-Branch

Alias:

Type: Tunnel Interface

Interface: port9

Role: Undefined

---

**Address**

Addressing mode: Manual

IP:

Network Mask: 255.255.255.255

Remote IP:

IPv6 Addressing mode: Manual DHCP

IPv6 Address/Prefix:

---

**Administrative Access**

IPv4

<input type="checkbox"/> HTTPS	<input type="checkbox"/> HTTP	<input type="checkbox"/> PING	<input type="checkbox"/> FMG-Access	<input type="checkbox"/> CAPWAP
<input type="checkbox"/> SSH	<input type="checkbox"/> SNMP	<input type="checkbox"/> FTM	<input type="checkbox"/> RADIUS Accounting	
<input checked="" type="checkbox"/> FortiTelemetry				

Your IPsec VPN interface will automatically be added to the FortiTelemetry enabled interface list under **Security Fabric > Settings**.

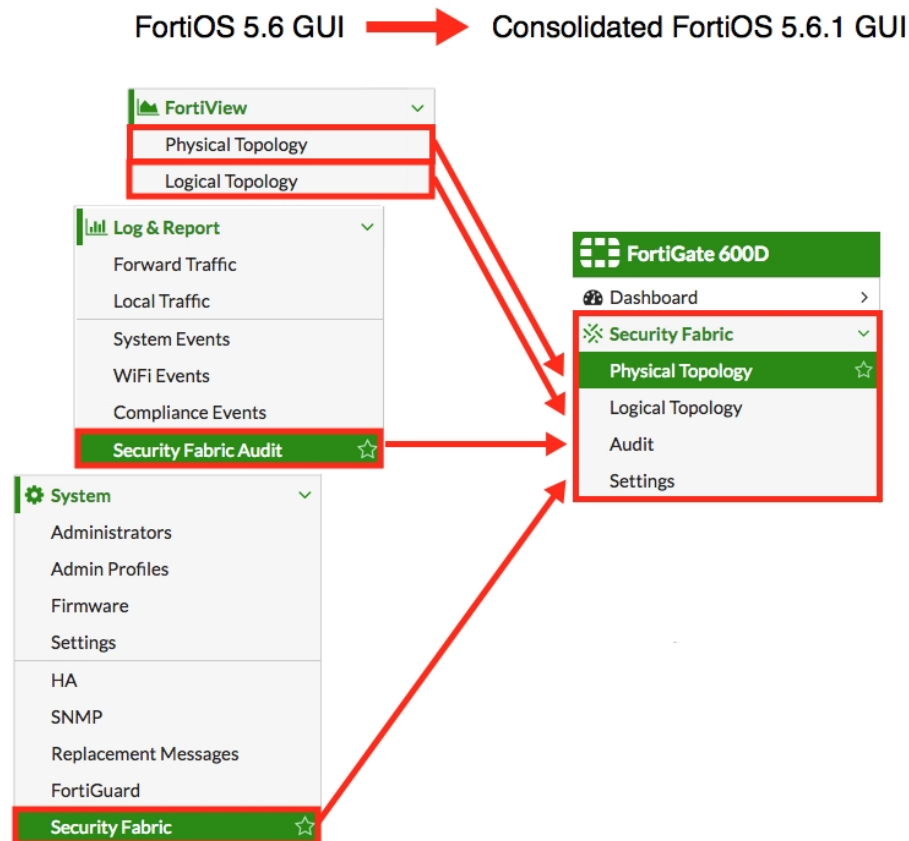

In the CLI, enter the following commands:

```
config system interface
  edit <vpn_name>
    set fortiheartbeat enable
  end
```

### Re-designed Security Fabric setup

A new updated GUI menu consolidates the Security Fabric features in one location. This includes **Physical Topology**, **Logical Topology**, **Audit**, and **Settings**. For more details, see the illustration below:

### Improved Security Fabric Settings page

The Security Fabric **Settings** page has been updated to act as a centralized location for you to enable connectivity to other Fortinet products. Navigate to **Security Fabric > Settings**.

Changes to the **Settings** page include the following:

- The previous **Enable Security Fabric** option has been replaced with an option to enable **FortiGate Telemetry**.
- The previous **Downstream FortiGates** option has been replaced with **Topology** to show multiple devices.

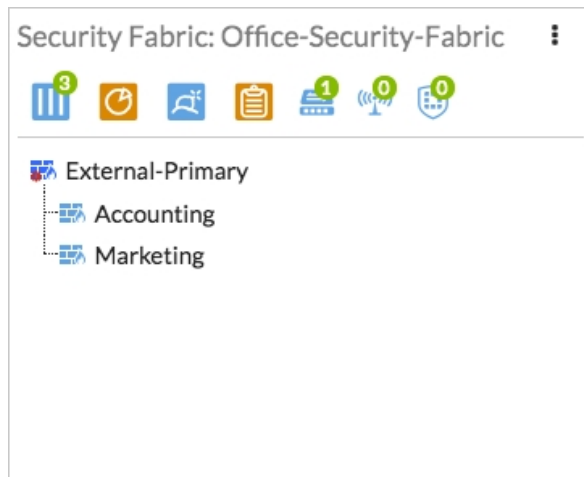

See the screen shot below:

### Security Fabric dashboard widgets

New dashboard widgets for the Security Fabric put information about the status of the Security Fabric at your fingertips when you first log into your FortiGate.

The FortiGate dashboard widget has been updated to include the following Fortinet products: FortiGate (core), FortiAnalyzer (core), FortiSwitch, FortiClient, FortiSandbox, and FortiManager. See the screen shot below:

You can hover over the icons along the top of the Security Fabric widget to get a quick view of the status of the Security Fabric. Available information includes the FortiTelemetry status and the status of various components of in the Security Fabric.

The Security Fabric Score widget shows the Security Fabric Audit score for the Security Fabric and allows you to apply recommended changes right from the dashboard.

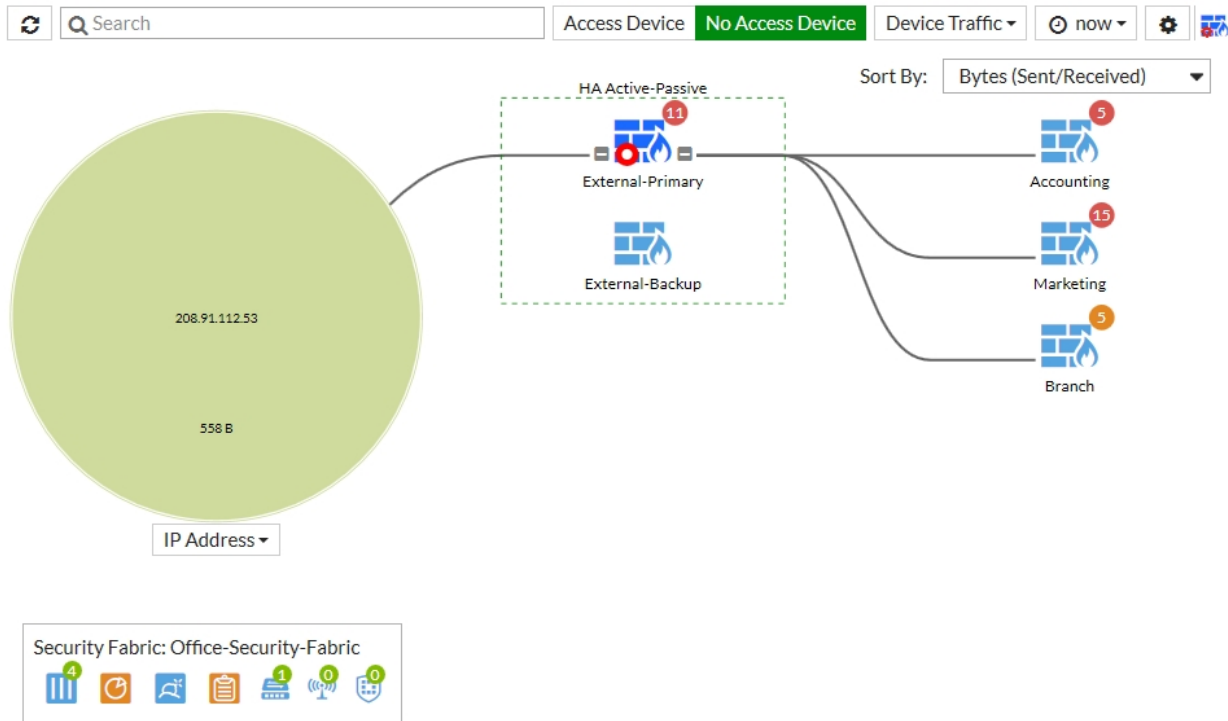

## Physical and Logical FortiView improvements

The FortiView Physical and Logical Topology pages now display the following improvements:

- Shows both FortiGates in an HA configuration
- Shows FortiAPs
- Lists FortiAnalyzer and FortiSandbox as components of the Security Fabric
- Highlights the current FortiGate

- Displays Link Usage in different colors
- Ranks Endpoints by FortiClient Vulnerability Score and by Threat Score ( see below, for more information)
- Displays user avatars
- Recognizes servers as a device type
- Introduces a search bar to help locate specific devices in the Security Fabric

### Updated Physical and Logical Topology legend

On the **Physical Topology** and **Logical Topology** pages, the Security Fabric legend has been updated. See the screenshot below:

### New option to minimize the Topology

This new feature allows you to minimize portions of the Physical and Logical Topology. This makes it easy to view your entire topology, or minimize portions to focus in on a specific area. See the screenshot below:

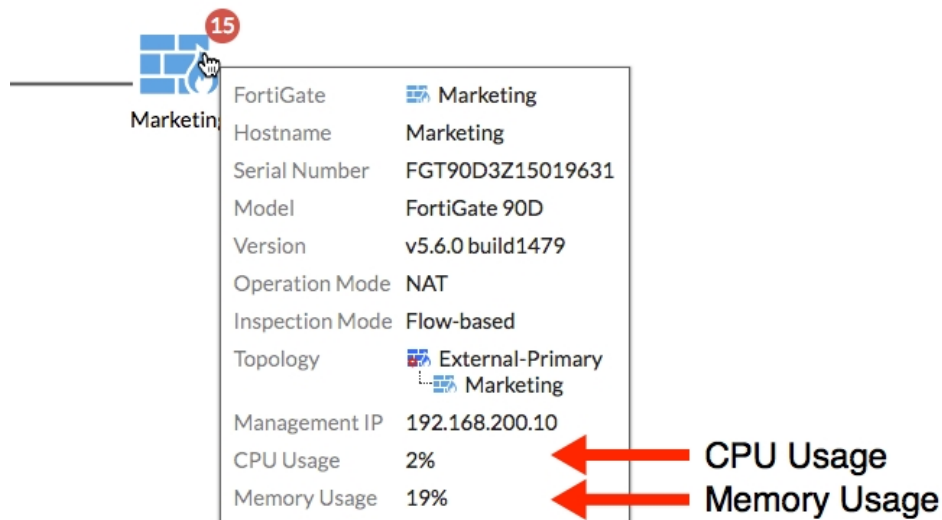

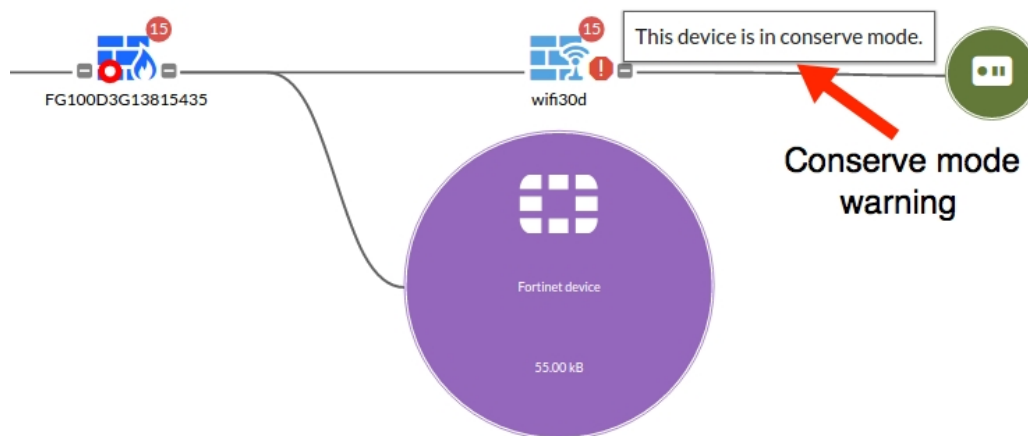

### Security Fabric Topology shows new resource information alerts

The enhanced Security Fabric topology now shows CPU Usage and Memory Usage alerts in the device information tooltip. It also displays a warning if the FortiGate is in conserve mode. Note that the CPU usage, memory usage and conserve mode data are drawn from the data that was last loaded from the FortiGate, not real-time data.

You can see the new CPU Usage and Memory Usage fields shown in the tooltip below:

The Conserve mode warning is shown below:

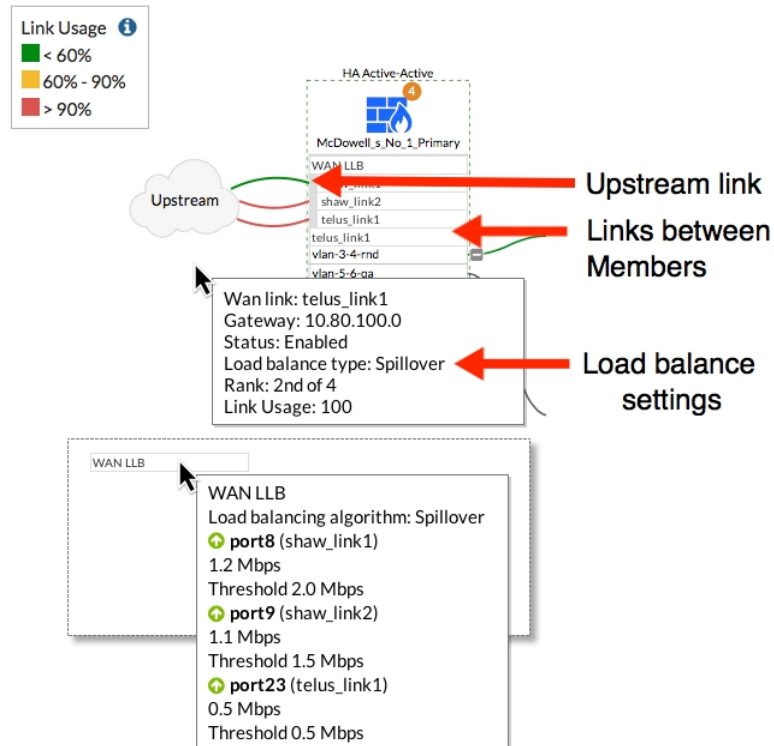

### SD-WAN information added to Security Fabric topology

The Security Fabric topology now includes SD-WAN. Enhancements include greater visibility into where the data comes from and goes to, link saturation indicators, and detailed tooltip explanations.

The following SD-WAN information has been integrated into the Security Fabric topology:

- The tooltip for the SD-WAN interface now includes load balancing settings.
- In the Security Fabric Logical Topology, SD-WAN and its interface members will appear above all interfaces.
- If connected to an upstream FortiGate, one link between the exact SD-WAN member and the upstream FortiGate will appear.
- If connected to a destination bubble, links between each enabled member and the destination bubble appear.
- Interface bandwidth and link utilization for other interfaces (WAN role interface) have been temporarily removed and will be added back in later.
- Fixes have been made to show vulnerabilities for multiple MAC addresses (402495) and to show the FortiSwitch serial and port (389158).

For more details see the screenshot below:

### SD-WAN Monitor Support added to Security Fabric (417210)

The Security Fabric now retrieves monitor information from all members of the Security Fabric and displays it in the GUI of the root FortiGate. Support was added for the Routing Monitor, DHCP Monitor and User Quarantine Monitor.

You can use the new drop down menu shown below to select the Security Fabric members:

### FortiCache support for the Security Fabric (435830)

FortiGates in the Security Fabric can now use FortiCache as a remote cache service. Previously, FortiCache was supported via WCCP re-direct only, but now FortiGates can use it as a local cache rather than redirecting via WCCP.

**In the GUI, follow the steps below:**

1. Go to **Security Fabric > Settings** and enable **HTTP Service**.
2. Set **Device Type** to **FortiCache** and add the **IP addresses** of the FortiCache devices.
3. You can also select **Authentication** and add a password if required. See the screenshot below:

**HTTP Service**

Device type: **FortiCache** FortiWeb

FortiCache IPs: 10.10.10.10

Authentication: ☒

Password: .....

**In the CLI, enter the following commands:**

```
config wanopt forticache-service
  set status enable
  set local-cache-id <local-cache-id>
  set remote-forticache-id <remote-forticache-id>
  set remote-forticache-ip <remote-forticache-ip>
end
```

- `status` - Enable/disable using FortiCache as web-cache storage
- `disable` - Use local disks as web-cache storage
- `enable` - Use a remote FortiCache as web-cache storage
- `local-cache-id` - The cache ID that this device uses to connect to the remote FortiCache
- `remote-forticache-id` - The ID of the FortiCache that the device connects to
- `remote-forticache-ip` - The IP address of the FortiCache the device connects to

### Enhanced Security Fabric audit tests for FortiGuard licenses (409156)

The Security Fabric audit now has separate audit tests for FortiGuard licenses based on whether the FortiGuard license is valid, expired, never been activated, or temporarily unavailable. Previously, the audit test performed one batch test on all FortiGuard licenses, regardless of the status of the licenses. Recommendations for individual licenses are also provided in the GUI tooltips.

You can see the new breakdown of pass or fail actions shown below:

- License valid = pass
- License expired = fail
- License never activated = fail
- License is unavailable (connection issue with FortiGuard) = pass

If a required **Feature Visibility** is disabled, the audit test for it will not show vulnerabilities. The audit will show a score of zero (or a pass). Go to **System > Feature Visibility** (previously the Feature Select menu) to make any changes.

**In the GUI, follow the steps below to check the status of your FortiGuard licenses:**

1. Go to **Security Fabric > Audit** to check the status of your FortiGuard licenses.
2. Follow the steps in the Security Fabric Audit wizard.

3. Expand **Firmware & Subscriptions**, and look at the **FortiGuard License Subscriptions** section to verify whether any recommended action is required. See the example below:

Issue	FortiGate	Result	Recommendation
<div> <div>Firmware &amp; Subscriptions</div> <div>5</div> </div>			
<b>FortiCare Support</b> FortiGate should be registered with FortiCare and have valid support coverage.	External-Primary	-50	Renew the following support coverage services that have expired: <ul style="list-style-type: none"> <li>Hardware Version (2017/05/08)</li> <li>Firmware (2017/05/08)</li> <li>Enhanced Support (2017/05/08)</li> <li>Comprehensive Support (2017/05/08)</li> </ul>
<b>FortiGuard License Subscriptions</b> All registered FortiGuard license subscriptions should be valid.	External-Primary	-50	Renew the following expired licenses: <ul style="list-style-type: none"> <li>AntiVirus (2017/05/08)</li> <li>IPS (2017/05/08)</li> </ul>

## FortiClient Vulnerability Score

Endpoints in the Security Fabric topology are now ranked by their FortiClient Vulnerability Score. This score is calculated by the severity of vulnerabilities found on the endpoint:

- critical vulnerability = 100 points
- high vulnerability = 50 points
- medium vulnerability = 5 points
- low vulnerability = 2 points
- info vulnerability = 1 point

## FortiView Consolidation

Information about the Security Fabric can now be seen throughout the FortiView dashboards on the upstream FortiGate, when the real-time view is used.

- You can right-click on an entry and select View Aggregated Details to see more information.
- The upstream FortiGate filters information to avoid counting traffic from the same hosts multiple times on each hop.

The upstream FortiGate also now has the option to end downstream FortiGate sessions or quarantine endpoints that connect to downstream FortiGates.

## Remote login to downstream FortiGates

You can now log into downstream FortiGates from the upstream FortiGate, by right-clicking on the downstream FortiGate when viewing the Security Fabric's topology using FortiView.

## Logging Consolidation and Improvements

Several changes have been made to improve logging for a Security Fabric.

### Sending all logs to a single FortiAnalyzer

By default, all FortiGates in the Security Fabric now send logs to a single FortiAnalyzer. The connection to the FortiAnalyzer is configured on the upstream FortiGate, then the settings are pushed to all other FortiGates.

In FortiOS 5.6, a FortiAnalyzer is required for the root FortiGate in the Security Fabric; however, downstream devices can be configured to use other logging methods through the CLI:

```
config system csf
    set logging-mode local
end
```

### Data Exchange with FortiAnalyzer

The following information about the Security Fabric configuration is now sent to the FortiAnalyzer:

- Topology info
- Interface roles
- LAT / LNG info
- Device asset tags

#### ☒ Security Fabric

Group name

Group password

Connect to upstream FortiGate ☐

#### ☒ FortiAnalyzer logging

IP Address

Storage Usage 

0% 59.00 MB / 23.13 GB

Upload Option 

Real Time

 Every Minute Every 5 Minutes

Encrypt Log Transmission ☒

### Retrieving Monitor Information

Monitors on the upstream FortiGate, such as the VPN Monitor, Route Monitor, and User Quarantine, can now view the information from downstream devices. You can use the button in the top right corner of the screen to change the FortiGate information that is displayed.

### Log Settings

Log statistics for each FortiGate in the Security Fabric are now shown when you go to **Log & Report > Log Settings**.

## Device Tree

The entire Security Fabric tree is now updated upward, and each node has an updated state of the whole subtree. The content is saved in the local file and upon request from the GUI or a diagnose command (dia sys csf downstream) it can be retrieved.

## Security Fabric Audit and Fabric Score

This chapter contains information about the Security Fabric Audit and Fabric Score, which together provide a method to continually monitor and improve your Security Fabric's configuration.

### What is the Security Fabric Audit?

The Security Fabric Audit is a feature on your FortiGate that allows you to analyze your Security Fabric deployment to identify potential vulnerabilities and highlight best practices that could be used to improve your network's overall security and performance.

### Why should you run a Security Fabric Audit?

Using the Security Fabric Audit helps you to tune your network's configuration, deploy new hardware and/or software, and gain more visibility and control of your network. Also, by checking your Security Fabric Score, which is determined based on how many checks your network passes/fails during the Audit, you can have confidence that your network is getting more secure over time.

### Running a Security Fabric Audit

The Security Fabric Audit must be run on the root FortiGate in the Security Fabric.

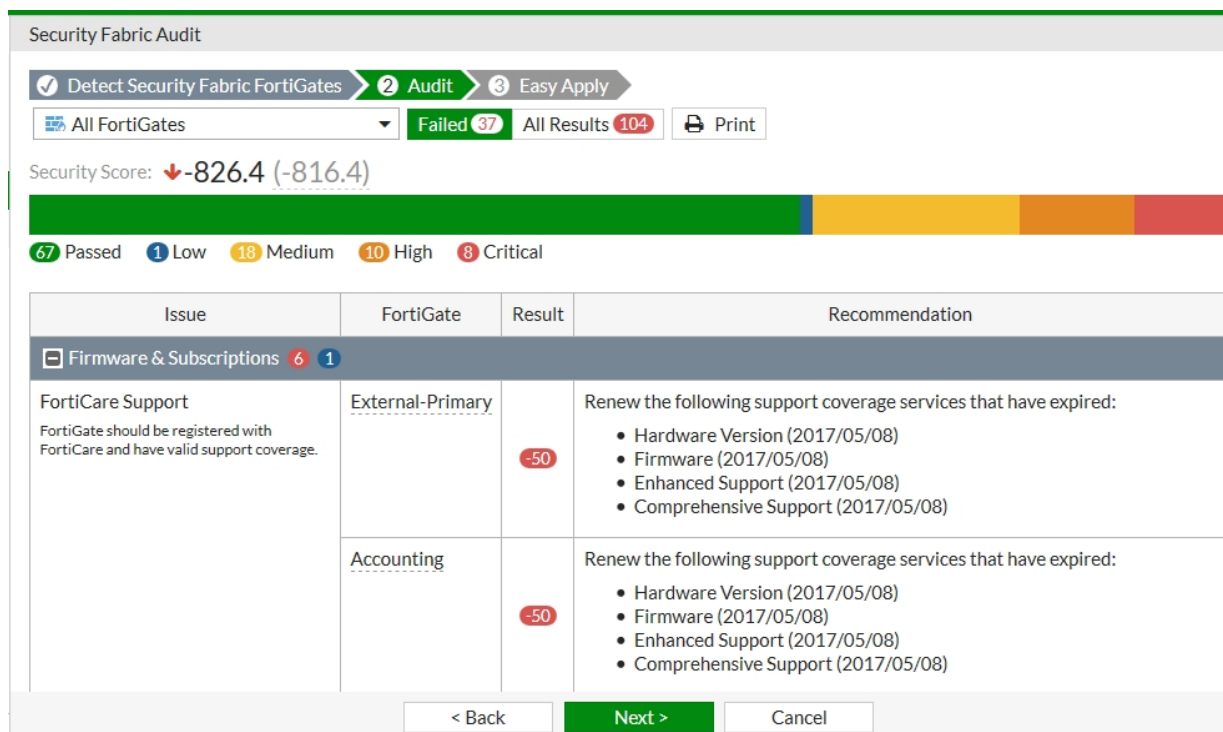

The Security Fabric Audit can be found by going to **Security Fabric > Audit**. In the first step, all detected FortiGates are shown.

1 Detect Security Fabric FortiGates 2 Audit 3 Easy Apply

i 4 FortiGate(s) detected in your security fabric.

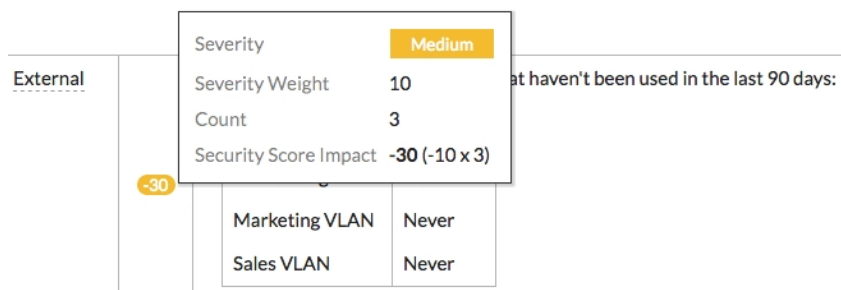

FortiGate	Model	Version
External	FortiGate 600D	v5.6.0 build1435
Sales	FortiGate 51E	v5.6.0 build1435
Accounting	FortiGate 140D	v5.6.0 build1435
Marketing	FortiGate 90D	v5.6.0 build1435

In the second step, the audit is performed and a list of recommendations are shown. Two views are available: **Failed** or **All Results**. These views can be further segmented so that you view results from all FortiGates or just a specific unit.

In each view, a chart appears showing the results of individual checks. The following information is shown: the name and a description of the check, which FortiGate the check occurred on, the checks result on your overall security score, and any necessary recommendations.

If you hover the mouse over the **Result** for a check, you can get a breakdown on how this score was determined. For more information about this, see ["Security Fabric Score" on page 73](#).

In Step Three of the Audit, **Easy Apply** recommendations are displayed and can be applied. By using **Easy Apply**, you can change the configuration of any FortiGate in the fabric.

For other recommendations, further action is required if you wish to follow the recommendation.

Detect Security Fabric FortiGates
Audit
**Easy Apply**

Backup configuration before applying any recommendations ☒

Issue	FortiGate	Result	Recommendation
<b>Internal Segmentation Firewall (ISFW)</b>			
Device Discovery Interfaces which are classified as "LAN" or "DMZ" should have device detection enabled.	Sales	 30	Enable device detection on the following interfaces:  lan
	Marketing	 30	Enable device detection on the following interfaces:  internal
<b>Endpoint Compliance</b>			
Endpoint Registration Interfaces which are classified as "LAN" should have FortiTelemetry enabled.	Marketing	 30	Enable FortiTelemetry on the following interfaces:  internal
<b>Security Best Practices</b>			
Detect Botnet Connections Interfaces which are classified as "WAN" should block or monitor outgoing connections to botnet sites.	Sales	 30	Block outgoing connections to botnet sites on the following interfaces:  wan1
	Accounting	 30	Block outgoing connections to botnet sites on the following interfaces:  wan1
	Marketing	 30	Block outgoing connections to botnet sites on the following interfaces:  wan1
Admin Password Policy A password policy should be set up for system administrators.	External	 10	Enable a simple password policy for system administrators.
	Sales	 10	Enable a simple password policy for system administrators.
	Accounting	 10	Enable a simple password policy for system administrators.
	Marketing	 10	Enable a simple password policy for system administrators.

You can also view Audit recommendations for specific devices using the FortiView Topology consoles. If a recommendation is available for a device, a circle containing a number appears. The number shows how many recommendations are available, while the color of the circle shows the severity of the highest check that failed (red is critical, orange is high, yellow is medium, and blue is low).

## Logging for the Security Fabric Audit

An event filter subtype is available for the Security Audit. Every time an audit is run, event logs are created on the root FortiGate that summarize the results of the audit, as well as details into the individual tests.

### Syntax

```
config log eventfilter
```

```

set security-audit {enable | disable} (enabled by default)
end

```

## Security Fabric Audit Checks

The Security Fabric Audit performs a variety of checks when analyzing your network. All checks are based on your current network configuration, using realtime monitoring. The Audit runs these checks across all FortiGates in the Security Fabric.

### Firmware & Subscriptions

Goal	Severity	Check	Recommendation	Easy Apply?
Compatible Firmware	Critical	All FortiGates in the Security Fabric should run the same firmware version.	Run same version as root.	No
FortiCare Support	Critical	FortiGate should be registered with FortiCare.	Register with FortiCare.	No
FortiGuard License Subscriptions	High	All registered FortiGuard license subscriptions should be valid.	Renew subscriptions.	No
FortiAP Firmware Versions	Low	All FortiAPs should be running the latest firmware.	Upgrade FortiAP to recommended version.	No
FortiSwitch Firmware Versions	Low	All FortiSwitches should be running the latest firmware.	Update all FortiSwitches to use the latest firmware.	No

### Internal Segmentation Firewall (ISFW)

Goal	Severity	Check	Recommendation	Easy Apply?
Interface Classification	High	All interfaces should be classified as either "LAN", "WAN", or "DMZ".	Configure the interface role.	Yes
Device Discovery	High	Interfaces which are classified as "LAN" or "DMZ" should have device detection enabled.	Enable device detection.	Yes
Third Party Router & NAT Devices	Medium	No third party router or NAT devices should be detected in the network.	Replace the device with a FortiGate.	No
VLAN Management	Medium	Non-FortiLink interfaces should not have multiple VLANs configured on them.	Use FortiSwitch and FortiLink.	No

Goal	Severity	Check	Recommendation	Easy Apply?
Centralized Logging & Reporting	High	Logging and reporting should be done in a centralized place throughout the Security Fabric.	Install FortiAnalyzer for logging & reporting.	No
LAN Segment	Medium	Servers should be placed behind interfaces classified as "DMZ".	All servers should be moved to interfaces with role "DMZ".	No
Unused Policies	Medium	All IPv4 policies should be used.	Review all IPv4 policies that haven't been used in the last 90 days.	No
Advanced Threat Protection	High	Suspicious files should be submitted to FortiSandbox or FortiSandbox Cloud for inspection.	Configure AntiVirus profiles to send files to FortiSandbox or FortiSandbox Cloud for inspection.	No
Unauthorized FortiAPs	Medium	All discovered FortiAPs should be authorized or disabled.	Authorize or disable unauthorized FortiAPs.	Yes
Unauthorized FortiSwitches	Medium	All discovered FortiSwitches should be authorized or disabled.	Authorize or disable unauthorized FortiSwitches.	Yes

### Endpoint Compliance

Goal	Severity	Check	Recommendation	Easy Apply?
Endpoint Registration	High	Interfaces which are classified as "LAN" should have FortiTelemetry enabled.	Enable FortiTelemetry on "LAN" interfaces.	Yes
FortiClient Protected	Medium	All supported devices should be registered via FortiClient.	Register all devices via FortiClient.	No
FortiClient Compliance	Medium	All registered FortiClient devices should be compliant with FortiClient profile.	Investigate non-compliant reason(s) for FortiClient endpoints.	No
FortiClient Vulnerabilities	Critical	All registered FortiClient devices should have no critical vulnerabilities.	Have FortiClient fix the detected critical vulnerabilities.	No

## Security Best Practices

Goal	Severity	Check	Recommendation	Easy Apply?
Detect Botnet Connections	High	Interfaces which are classified as "WAN" should block or monitor outgoing connections to botnet sites	Enable botnet detection on "WAN" interfaces.	Yes
Unsecure Protocol - HTTP	High	Interfaces which are classified as "WAN" should not allow HTTP administrative access.	Enable HTTPS redirection globally.	Yes
Unsecure Protocol - Telnet	High	Interfaces which are classified as "WAN" should not allow Telnet administrative access.	Disable Telnet.	Yes
Valid HTTPS Certificate - Administrative GUI	Medium	The administrative GUI should not be using a default built-in certificate.	Acquire a certificate for your domain, upload it, and configure the administrative GUI to use it.	No
Valid HTTPS Certificate - SSL VPN	Medium	SSL VPN should not be using a default built-in certificate.	Acquire a certificate for your domain, upload it, and configure SSL VPN to use it.	No
Explicit Interface Policies	Low	Policies that allow traffic should not be using the "any" interface.	Change the policy to use a specific interface.	No
Admin Password Policy	Medium	A password policy should be setup for system administrators.	Enable a simple password policy for system administrators.	Yes

## Security Fabric Score

The **Security Fabric Score** widget has been added to the FortiGate Dashboard to give visibility into auditing trends. This widget uses information from the Security Fabric Audit to determine your score. Score can be positive or negative, with a higher score representing a more secure network.

**Score** is based on the number of checks failed and the severity of these checks. The weight for each severity level is as follows:

- Critical: 50 points
- High: 25 points
- Medium: 10 points
- Low: 5 points

You get points for passing a test only when it passes for all FortiGates in your fabric. If this occurs, the score is calculated using this formula:

$$+ \text{Severity Weight} \times \text{Secure FortiGate Multiplier}$$

The Severity Weight is calculated as Severity divided by the number of FortiGates in the Fabric. The Secure FortiGate Multiplier is determined using logarithms and the number of FortiGates in the fabric. For example, if you have four FortiGates in your fabric that all pass the Compatible Firmware check, your score for each individual FortiGate is:

$$(50/4) \times 1.292 = 16.2 \text{ points}$$

If a test fails on any FortiGate in your Fabric, all other FortiGates that passed the check award 0 points. For the FortiGate the test failed on, the score is calculated using this formula:

$$- \text{Severity Weight} \times \text{Count}$$

Count is the number of times the check failed during the audit. For example, if two critical FortiClient vulnerabilities are discovered during the Audit, your score for that check is:

$$-50 \times 2 = -100 \text{ points}$$

For checks that do not apply, your score does not change. For example, if you have no FortiAPs in the fabric, you will receive no points for the FortiAP Firmware Versions check.

## New Dashboard Features

The FortiOS 5.6 **Dashboard** has a new layout with a Network Operations Center (NOC) view with a focus on alerts. Widgets are interactive; by clicking or hovering over most widgets, the user can get additional information or follow links to other pages.

Enhancements to the GUI dashboard and its widgets are:

- Multiple dashboard support.
- VDOM and global dashboards.
- Updated resize control for widgets.
- Notifications moved to the top header bar (moved existing dashboard notifications to the header and added additional ones).
- Reorganization of **Add Widget** dialog.
- New **Host Scan Summary** widget.
- New **Vulnerabilities Summary** widget that displays endpoint vulnerability information much like the FortiClient Enterprise Management Server (EMS) summary.
- Multiple bug fixes.

Features that were only visible through old dashboard widgets have been placed elsewhere in the GUI:

- Restore configuration.
- Configuration revisions.
- Firmware management.
- Enabling / disabling VDOMs.
- Changing inspection mode.
- Changing operation mode.
- Shutdown / restart device.
- Changing hostname.
- Changing system time.

The following **widgets** are displayed by default:

- [System Information](#)
- [Licenses](#)
- [FortiCloud](#)

- [Security Fabric](#)
- [Administrators](#)
- [CPU](#)
- [Memory](#)
- [Sessions](#)
- [Bandwidth](#)
- [Virtual Machine](#) (on VMs and new to FortiOS 5.6.1)

The following **optional** widgets are available:

- Interface Bandwidth
- Disk Usage
- Security Fabric Risk
- Advanced Threat Protection Statistics
- Log Rate
- Session Rate
- Sensor Information
- HA Status
- Host Scan Summary
- Vulnerabilities Summary
- FortiView (new to FortiOS 5.6.1)

The following widgets have been **removed**:

- CLI Console
- Unit Operation
- Alert Message Console

## System Information

**System Information**

Hostname	FG100D3G15818864
Serial Number	FG100D3G15818864
Firmware	v5.6.0 build1435
Mode	NAT (Proxy-based)
System Time	2017/03/22 14:05:04
Uptime	00:00:31:34
WAN IP	209.87.240.98 (🇨🇦 Kanata, Ontario, Canada)

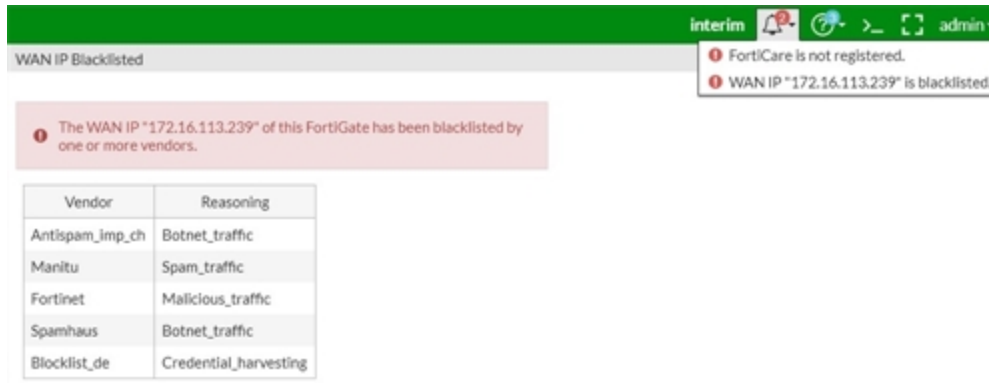

Configure settings in System > Settings

Update firmware in System > Firmware

Only appears when you click on the widget. Click on the System page you want to go to.

### FortiGuard WAN IP blacklist service is now online

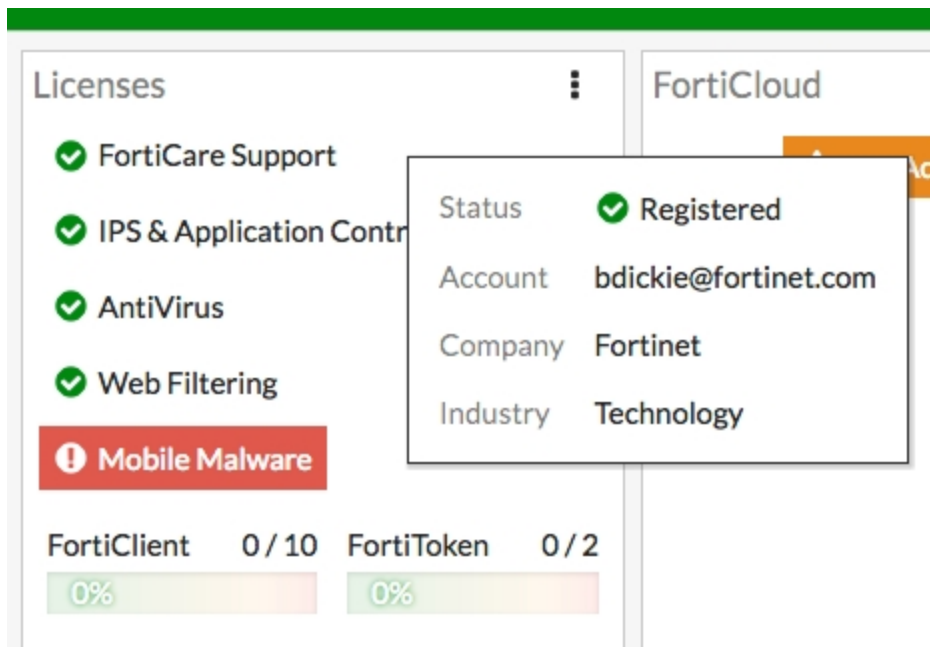

The FortiGuard WAN IP blacklist service was not online in FortiOS 5.6.0. In FortiOS 5.6.1, a notification appears on the **Dashboard** when WAN IP is blacklisted. Clicking on the notification (bell icon) brings up the blacklist details.

### Licenses

Hovering over the **Licenses** widget will cause status information (and, where applicable, database information) on the licenses to be displayed for **FortiCare Support**, **IPS & Application Control**, **AntiVirus**, **Web Filtering**, **Mobile Malware**, and **FortiClient**. The image below shows **FortiCare Support** information along with the registrant's company name and industry.

Clicking in the **Licenses** widget will provide you with links to other pages, such as **System > FortiGuard** or contract renewal pages.

## FortiCloud

This widget displays FortiCloud status and provides a link to activate FortiCloud.

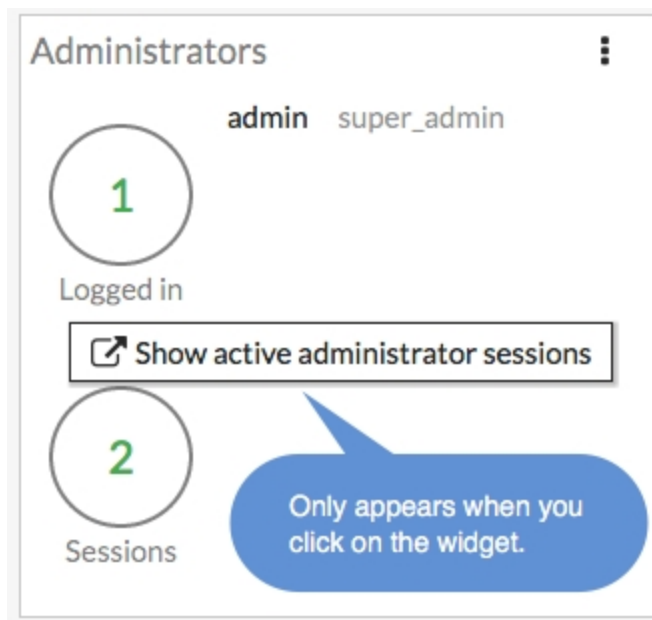

## Fortinet Security Fabric

The **Security Fabric** widget is documented in the [Security Fabric](#) section of the **What's New** document.

## Administrators

This widget allows you to view which administrators are logged in and how many sessions are active. The link directs you to a page displaying active administrator sessions.

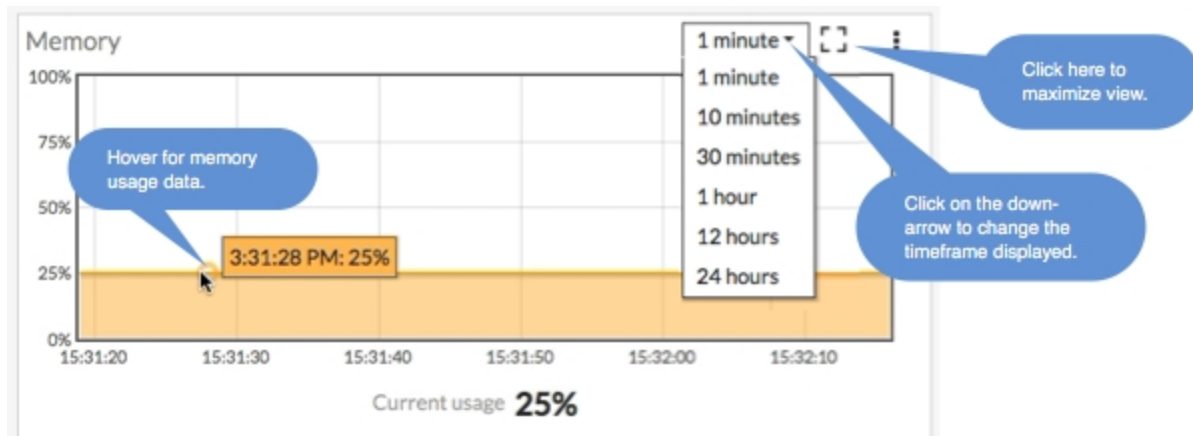

## CPU

The real-time CPU usage is displayed for different timeframes.

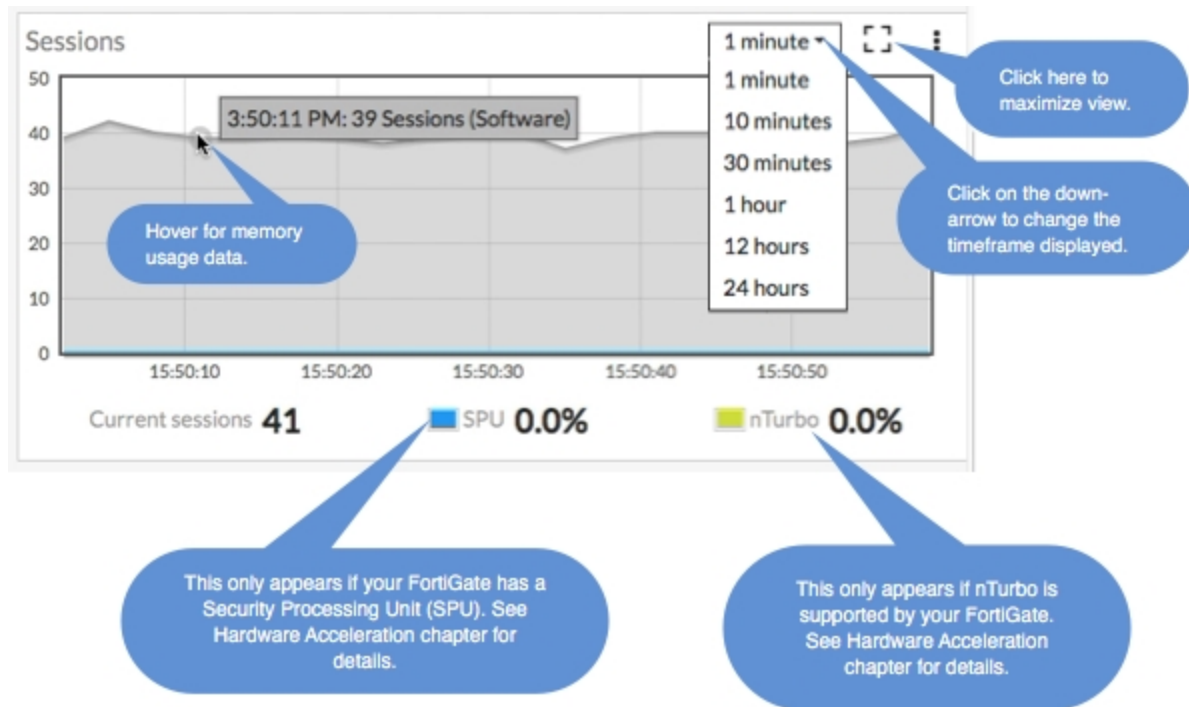

## Memory

Real-time memory usage is displayed for different time frames. Hovering over any point on the graph displays percentage of memory used along with a timestamp.

## Sessions

## Bandwidth

## Virtual Machine

FortiOS 5.6.1 introduces a VM widget with these features:

- License status and type.
- CPU allocation usage.
- License RAM usage.
- VMX license information (if the VM supports VMX).
- If the VM license specifies 'unlimited' the progress bar is blank.
- If the VM is in evaluation mode, it is yellow (warning style) and the dashboard show evaluation days used.
- Widget is shown by default in the dashboard of a FortiOS VM device.
- Removed VM information from License widget at **Global > Dashboard**.
- License info and **Upload License** button provided on page **Global > System > FortiGuard**.
- Updated 'Upload VM License' page:
  - Added license RAM usage and VMX instance usage.
  - Replaced file input component.

## FortiExplorer for iOS

A new iOS FortiExplorer app is available as of April 8, 2017.

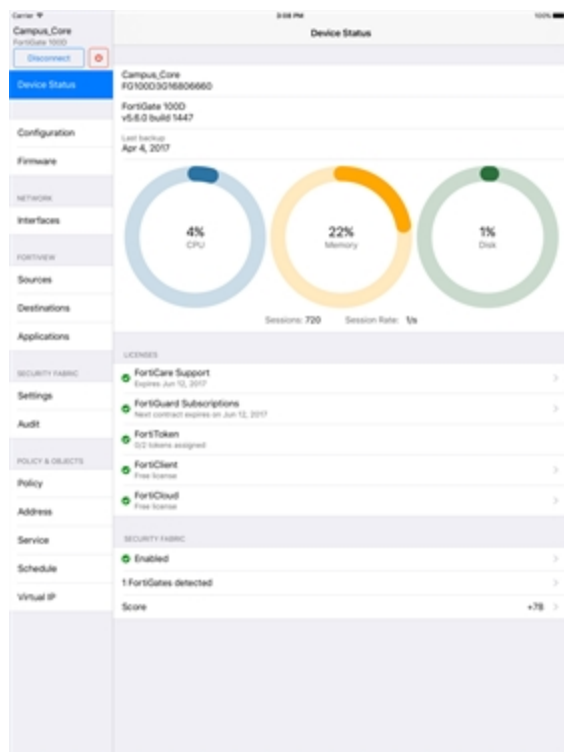

FortExplorer for iOS is compatible with iPhone, iPad, and iPod Touch and supports configuration via REST API and display of FortiView and other security fabric components.

You can use FortiExplorer for iOS to perform most FortiOS configuration management tasks.

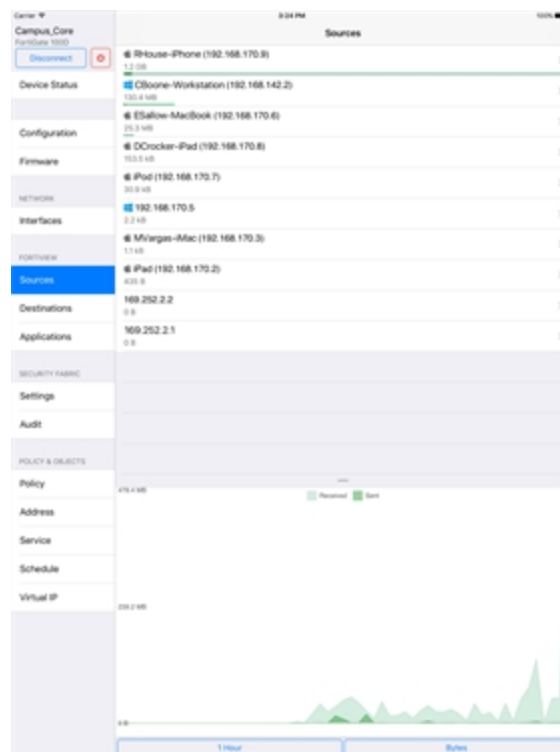

Advanced features will be available with the purchase of an add-on through the App Store. These paid features include the adding more than two devices and downloading firmware images from FortiCare.

With the release of FortiOS 5.6.1, FortiOS icons and colors are now exportable in the GUI shared project and FortiExplorer now uses these icons and colors. This change improves the icon colors only for the FortiExplorer GUI theme (seen only when accessing a web GUI page from within the FortiExplorer iOS app).

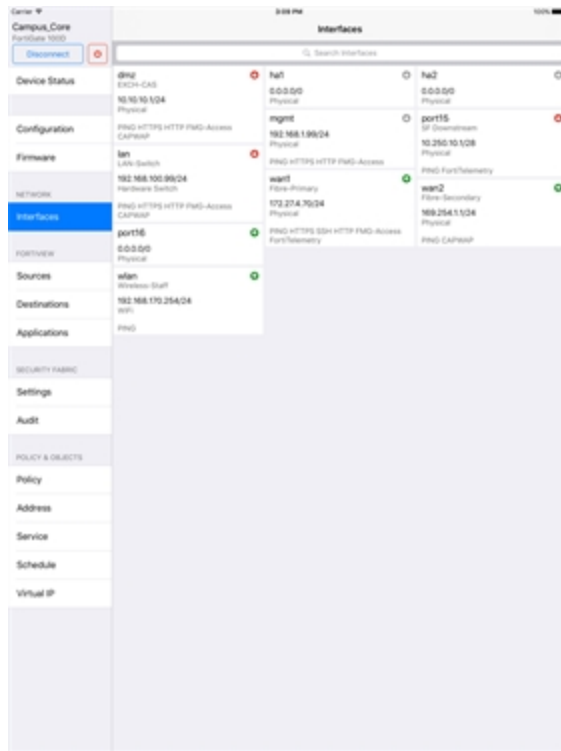

The images below offer a preview of a few of the new FortiExplorer iOS app's screens.

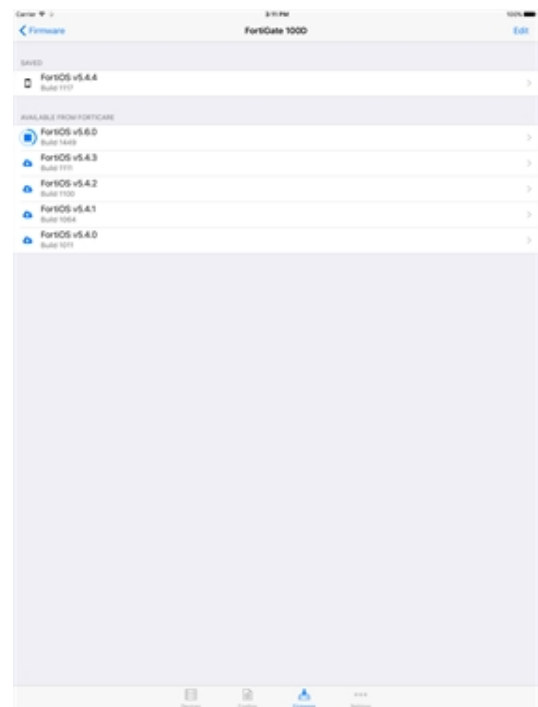

FortiExplorer iOS, v 1.0 - Device Status

FortiExplorer iOS, v. 1.0 - Sources

FortiExplorer iOS, v.1.0 - Device Interfaces

FortiExplorer iOS, v.1.0 - Firmware

## Transparent web proxy (386474)

In addition to the Explicit Web Proxy, FortiOS now supports a Transparent web proxy. While it does not have as many features as Explicit Web Proxy, the transparent proxy has the advantage that nothing needs to be done on the user's system to forward supported web traffic over to the proxy. There is no need to reconfigure the browser or publish a PAC file. Everything is transparent to the end user, hence the name. This makes it easier to incorporate new users into a proxy deployment.

You can use the transparent proxy to apply web authentication to HTTP traffic accepted by a firewall policy. In previous versions of FortiOS, web authentication required using the explicit proxy.

Normal FortiOS authentication is IP address based. Users are authenticated according to their IP address and access is allowed or denied based on this IP address. On networks where authentication based on IP address will not work you can use the Transparent Web proxy to apply web authentication that is based on the user's browser and not on their IP address. This authentication method allows you to identify individual users even if multiple users on your network are connecting to the FortiGate from the same IP address.

### Using the Transparent proxy

To implement the Transparent proxy, go to **System > Settings** and scroll down to **Operations Settings** and set the inspection mode to **Proxy**.

### Operations Settings

Inspection Mode

Flow-based

Proxy

Virtual Domains ☐

Then go to **System > Feature Visibility** and enable **Explicit Proxy**.

Then go to **Security Profiles > Proxy Options**, edit a proxy options profile and under **Web Options** enable **HTTP Policy Redirect**.

### Web Options

Chunked Bypass

Add Fortinet Bar

HTTP Policy Redirect

Then go to **Policy & Objects > IPv4 Policy** and create or edit a policy that accepts traffic that you want to apply web authentication to. This can be a general policy that accepts many different types of traffic as long as it also accepts the web traffic that you want to apply web authentication to.

Select a **Security Profile** and select the **Proxy Options** profile that you enabled **HTTP Policy Redirect** for.

Name 	General Internet Access Policy	
Incoming Interface	 port2	▼
Outgoing Interface	 port1	▼
Source	 all	✕
Destination	 all	✕
Schedule	 always	▼
Service	 ALL	✕
Action	<input checked="" type="checkbox"/> ACCEPT <input type="checkbox"/> DENY <input type="checkbox"/> LEARN	

### Firewall / Network Options

NAT	<input checked="" type="checkbox"/>
IP Pool Configuration	<input checked="" type="checkbox"/> Use Outgoing Interface Address <input type="checkbox"/> Use Dynamic IP Pool

### Security Profiles

AntiVirus	<input checked="" type="checkbox"/>	 default	
Web Filter	<input type="checkbox"/>		
DNS Filter	<input type="checkbox"/>		
Application Control	<input type="checkbox"/>		
IPS	<input type="checkbox"/>		
Proxy Options		 default	
SSL/SSH Inspection		 certificate-inspection	

Then go to **Policy & Objects > Proxy Policy** create a Transparent Proxy policy to accept the traffic that you want to apply web authentication to. Set the **Proxy Type** to **Transparent Web**. The incoming interface, outgoing interface, destination address, and schedule should either match or be a subset of the same options defined in the IPv4 policy. Addresses added to the Source must match or be a subset of the source addresses added to the IPv4 policy. You can also add the users to be authenticated by the transparent policy to the source field.

Select other transparent policy options as required.

Proxy Type 	Explicit Web	<b>Transparent Web</b>	FTP
Incoming Interface	 port2 ▼		
Outgoing Interface	 port1 ▼		
Source	 web_users ✕

Comments	<input type="text" value="Write a comment..."/> 0/1023	

### More about the transparent proxy

The following changes are incorporated into Transparent proxy, some of which affect Explicit Web Proxy as well.

#### Flat policies

The split policy feature has been removed. This will make the explicit policy more like the firewall policy.

## Authentication

The new authentication design is intended to separate authentication from authorization. Authentication has been moved into a new table in the FortiOS. This leaves the authorization as the domain of the explicit proxy policy.

**Previously**, if authentication was to be used:

1. The policy would be classified as an identity based policy
2. The policy would be split to add the authentication parameters
3. The authentication method would be selected
4. The user/group would be configured

**Now:**

The user/group is configured in the proxy policy

1. A new authentication rule is added
2. This option refers to the authentication scheme
3. The authentication scheme has the details of the authentication method

### The new authentication work flow for Transparent Proxy:

Toggle the transparent-http-policy match:

```
config firewall profile-protocol-options
  edit <profile ID>
    config http
      set http-policy <enable|disable>
```

If disabled, everything works like before. If enabled, the authentication is triggered differently.

- http-policy work flow:
- For transparent traffic, if there is a regular firewall policy match, when the Layer 7 check option is enabled, traffic will be redirected to WAD for further processing.
- For redirected traffic, layer 7 policy (HTTP policy) will be used to determine how to do security checks.
- If the last matching factor is down to user ID, then it will trigger a new module to handle the L7 policy user authentication.
- Then propagate learned user information back to the system so that it can be used to match traffic for L4 policy.

## New Proxy Type

There is a new subcategory of proxy in the proxy policy called **Transparent Web**. The old **Web Proxy** is now referred to as **Explicit Web Proxy**.

- This is set in the firewall policy
- It is available when the HTTP policy is enabled in the profile-protocol options for the firewall policy
- This proxy type supports OSI layer 7 address matching.
- This proxy type should include a source address as a parameter
- Limitations:
  - It can be used for HTTPS traffic, if deep scanning is not used
  - It only supports SNI address matching, i.e. domain names

- It does not support header types of address matching
- It only supports SSO authentication methods, no active authentication methods.

### IP pools support

Proxies are now supported on outgoing IP pools.

### SOCKSv5

SOCKSv5 authentication is now supported for explicit proxies.

To configure:

```
config authentication rule
edit <name of rule>
set protocol socks
end
```

### Forwarding

Proxies support URL redirect/forwarding. This allows a non-proxy forwarding server to be assigned a rule that will redirect web traffic from one URL to another, such as redirecting traffic destined for youtube.com to restrict.youtube.com.

- A new option called "Redirect URL" has been added to the policy
- Traffic forwarding by VIP is supported

### Support for explicit proxy address objects & groups into IPv4 firewall policies

This would allow the selection of web filter policy, SSL inspection policy, and proxy policy based on source IP + destination (address|explicit proxy object|category|group of any of those). This enables things like "do full SSL interception on www.google.com, but not the rest of the Search Engines category".

### Support application service in the proxy based on HTTP requests.

The application service can be configured using the following CLI commands:

```
config firewall service custom
edit <name of service>
set explicit-proxy enable
set app-service-type <disable|app-id|app-category>
set app-category <application category ID, integer>
set application <application ID, integer>
end
```

### CLI

#### Changes:

Previous	New
<code>config firewall explicit-proxy-policy</code>	<code>config firewall proxy-policy</code>

Previous	New
<code>config firewall explicit-proxy-address</code>	<code>config firewall proxy-address</code>
<code>config firewall explicit-proxy-addrgrp</code>	<code>config firewall proxy-addrgrp</code>
<pre>config firewall explicit-proxy-policy edit &lt;policy ID&gt; set proxy web end</pre>	<pre>config firewall proxy-policy edit &lt;policy ID&gt; set proxy explicit-web end</pre>

### Removals:

- "split-policy" from firewall explicit-proxy-policy.

The previous method to set up a split policy was:

```
config firewall explicit-proxy-policy
edit 1
set proxy web
set identity-based enable
config identity-based-policy
edit 1
set schedule "always"
set utm-status enable
set users "guest"
set profile-protocol-options "default"
next
end
next
end
```

- "auth relative" from firewall explicit-proxy-policy

The following attributes have been removed from firewall explicit-proxy-policy:

- identity-based
- ip-based
- active-auth-method
- sso-auth-method
- require-tfa

### Moves:

users and groups from

```
firewall explicit-proxy-policy identity-based-policy
to
config firewall proxy-policy
edit 1
set groups <Group name>
set users <User name>
end
```

## Additions:

### authentication scheme

```
config authentication scheme
edit <name>
set method [ntlm|basic|digest|form|negotiate|fsso|rsso|none]
```

- `ntlm` - NTLM authentication.
- `basic` - Basic HTTP authentication.
- `digest` - Digest HTTP authentication.
- `form` - Form-based HTTP authentication.
- `negotiate` - Negotiate authentication.
- `fsso` - FSSO authentication.
- `rsso` - RADIUS Single Sign-On authentication.
- `none` - No authentication.

### authentication setting

```
config authentication setting
set active-auth-scheme <string>
set sso-auth-scheme <string>
set captive-portal <string>
set captive-portal-port <integer value from 1 to 65535>
```

- `active-auth-scheme` - Active authentication method.
- `sso-auth-scheme` - SSO authentication method.
- `captive-portal` - Captive portal host name.
- `captive-portal-port` - Captive portal port number.

### authentication rule

```
config authentication rule
edit <name of rule>
set status [enable|disable]
set protocol [http|ftp|socks]
set srcaddr <name of address object>
set srcaddr6 <name of address object>
set ip-based [enable|disable]
set active-auth-method <string>
set sso-auth-method <string>
set web-auth-cookie [enable|disable]
set transaction-based [enable|disable]
set comments
```

- `status` - Enable/disable auth rule status.
- `protocol` - set protocols to be matched
- `srcaddr` / `srcaddr6` - Source address name. [`srcaddr` or `srcaddr6`(web proxy only) must be set].
- `ip-based` - Enable/disable IP-based authentication.
- `active-auth-method` - Active authentication method.
- `sso-auth-method` - SSO authentication method (require `ip-based` enabled)

- `web-auth-cookie` - Enable/disable Web authentication cookie.
- `transaction-based` - Enable/disable transaction based authentication.
- `comments` - Comment.

## NGFW Policy Mode (397035)

You can operate your FortiGate or individual VDOMs in **Next Generation Firewall (NGFW) Policy Mode**.

You can enable NGFW policy mode by going to **System > Settings**, setting the **Inspection mode** to **Flow-based** and setting the NGFW mode to **Policy-based**. When selecting **NGFW policy-based** mode you also select the SSL/SSH Inspection mode that is applied to all policies

**Flow-based** inspection with profile-based **NGFW mode** is the default in FortiOS 5.6.

Inspection Mode	<div>Flow-based Proxy</div>
NGFW Mode	<div>Profile-based Policy-based</div>
SSL/SSH Inspection	<div>SSL deep-inspection ▼</div>

Or use the following CLI command:

```
config system settings
  set inspection-mode flow
  set policy-mode {standard | ngfw}
end
```

## NGFW policy mode and NAT

If your FortiGate is operating in NAT mode, rather than enabling source NAT in individual NGFW policies you go to **Policy & Objects > Central SNAT** and add source NAT policies that apply to all matching traffic. In many cases you may only need one SNAT policy for each interface pair. For example, if you allow users on the internal network (connected to port1) to browse the Internet (connected to port2) you can add a port1 to port2 Central SNAT policy similar to the following:

### New Central SNAT Policy

Incoming Interface	<div> port1</div> <div>+</div> <div></div>
Outgoing Interface	<div> port2</div> <div>+</div> <div></div>
Source address	<div> all</div> <div>+</div> <div></div>
Destination address	<div> all</div> <div>+</div> <div></div>

### ☒ NAT

IP Pool Configuration	<div>Use Outgoing Interface Address</div> <div>Use Dynamic IP Pool</div>
Protocol	<div>ANY</div> <div>TCP</div> <div>UDP</div> <div>SCTP</div> <div>Specify</div> <div>0</div>

### Application control in NGFW policy mode

You configure **Application Control** simply by adding individual applications to security policies. You can set the action to accept or deny to allow or block the applications.

Name 	Block YouTube	
Incoming Interface	 port1	▼
Outgoing Interface	 port2	▼
Source	 all	✕
	+	
Destination	 all	✕
	+	
Schedule	 always	▼
Service	 ALL	✕
	+	
Application	 YouTube ✕  YouTube_Channel.Access ✕  YouTube_HD.Streaming ✕  YouTube_Video.Access ✕  YouTube_Video.Embedded ✕ +	
URL Category	+	
Action	 ACCEPT  DENY  LEARN	

### Web Filtering in NGFW mode

You configure **Web Filtering** by adding URL categories to security policies. You can set the action to accept or deny to allow or block the applications.

Name 	Block Streaming Websites	
Incoming Interface	 port1	▼
Outgoing Interface	 port2	▼
Source	 all	✕
	+	
Destination	 all	✕
	+	
Schedule	 always	▼
Service	 ALL	✕
	+	
Application	+	
URL Category	Streaming Media and Download	✕
	+	
Action	 ACCEPT  <b>DENY</b>  LEARN	

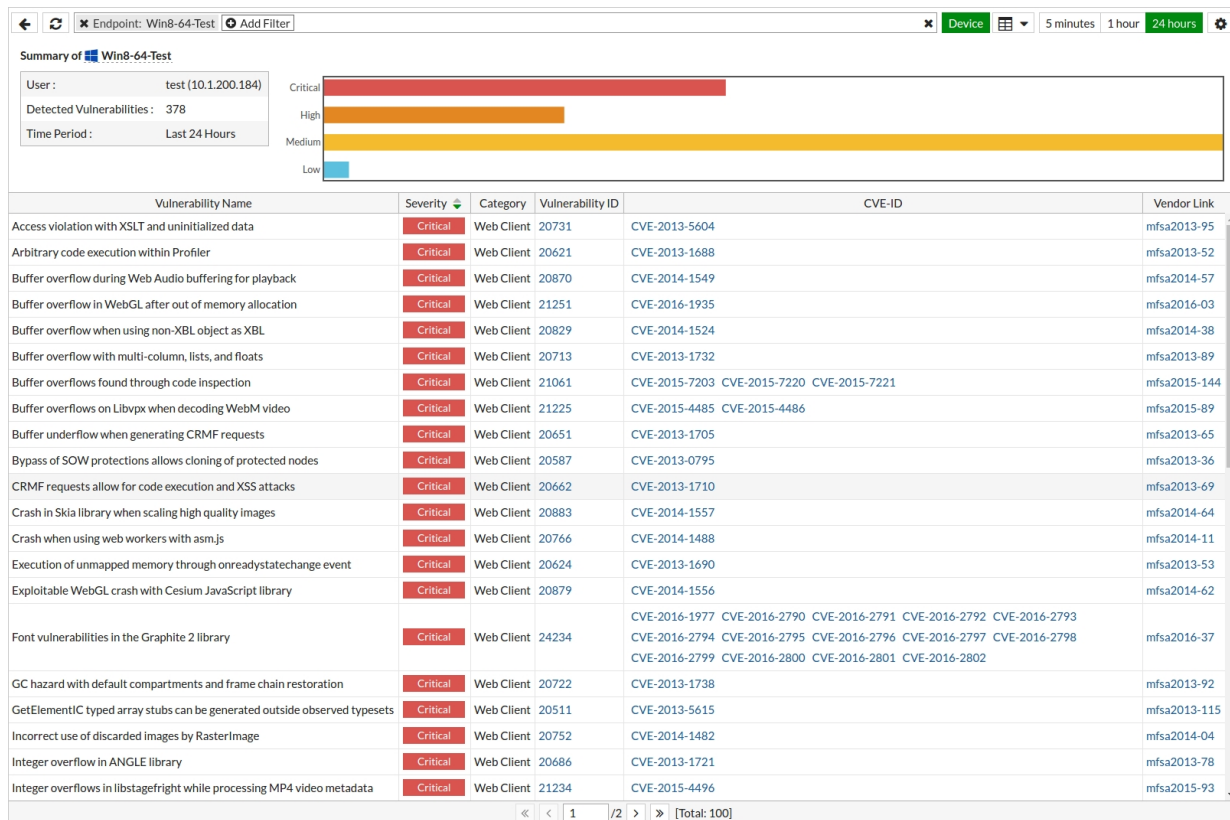

### Other NGFW policy mode options

You can also combine both application control and web filtering in the same NGFW policy mode policy. Also if the policy accepts applications or URL categories you can also apply Antivirus, DNS Filtering, and IPS profiles in NGFW mode policies as well a logging and policy learning mode.

### New FortiView Endpoint Vulnerability Scanner chart (378647)

FortiOS 5.6.0 adds a new chart to illustrate Endpoint Control events: **Endpoint Vulnerability**.

This is a list/bubble chart, that tracks vulnerability events detected by the FortiClients running on all devices registered with the FortiGate. FortiView displays information about the vulnerability and the device on which it was detected.

### Notes about the Endpoint Vulnerability Chart:

- You can sort the list by **Device** or **Vulnerability**.
- You can drill down into any device to see the Vulnerabilities detected. From there, you can drill down to see the exact Vulnerability Scan events that triggered the detection.
- Select any Vulnerability Scan event to see the associated Log data.

## FortiClient Profile changes (386267, 375049)

### FortiClient profile improvements (386267, 375049)

FortiClient profiles have been changed in FortiOS 5.6 to include new protection features and to change organization of the GUI options. FortiClient profiles also use the FortiGate to warn or quarantine endpoints that are not compliant with a FortiClient profile.

A bug that prevented the Dialog and Device Inventory pages from loading when there is a large number of devices (for example, 10,000) has been fixed.

### Default FortiClient profile

FortiClient profiles allow you to perform vulnerability scans on endpoints and make sure endpoints are running compliant versions of FortiClient. Also, security posture features cause FortiClient to apply realtime protection, AntiVirus, web filtering, and application control on endpoints.

Profile Name

Comments  0/255

### Telemetry Data

Endpoints must send telemetry data to FortiGate for Security Fabric.  
Non-compliant endpoints will be issued a warning.

Non-compliance action

☐ Endpoint Vulnerability Scan on Client

☐ System Compliance

☐ Security Posture Check

The default FortiClient profile also allows you to set a general **Non-compliance action** for endpoints that don't have FortiClient installed on them. The non-compliance action can be block or warning and is applied by the FortiGate. Blocked endpoints are quarantined by the FortiGate.

### Endpoint vulnerability scanning

Similar to FortiOS 5.4 you can set the FortiClient Profile to run the FortiClient vulnerability scanner on endpoints and you can set the Vulnerability quarantine level to quarantine endpoints that don't comply.

☒ Endpoint Vulnerability Scan on Client

Vulnerability quarantine level

Non-compliance action

The vulnerability scan **Non-compliance action** can block or warn endpoints if the vulnerability scan shows they do not meet the vulnerability quarantine level.

### System compliance

FortiOS 5.6 system compliance settings are similar to those in 5.4 with the addition of a non-compliance action. System compliance checking is performed by FortiClient but the non-compliance action is applied by the FortiGate.

### System Compliance

Minimum FortiClient version 

Windows endpoints

Mac endpoints

Upload Logs to FortiAnalyzer   ☒ Traffic ☒ Vulnerability  
☒ Event

Non-compliance action

### Security posture checking

Security posture checking collects realtime protection, antivirus protection, web filtering and application firewall features under the **Security Posture Check** heading.

### Security Posture Check

Realtime Protection 

Up-to-date signatures 

Scan with FortiSandbox  

Third party AntiVirus on Windows   

Web Filter 

Profile  default 

Application Firewall 

Application Control sensor  default 

Non-compliance action

### Application Control is now standard with FortiCare support

Application Control is now a standard part of any FortiCare support contract and the database for Application Control signatures is separate from the Intrusion Prevention System (IPS) database. However, botnet application signatures are still part of the IPS signature database since these are more closely related to security issues than application detection.

With the release of FortiOS 5.6.1, the Application Control signature database information is displayed under the **System > FortiGuard** page, in the FortiCare section. The botnet category is no longer available when you search for the Application Signatures list.

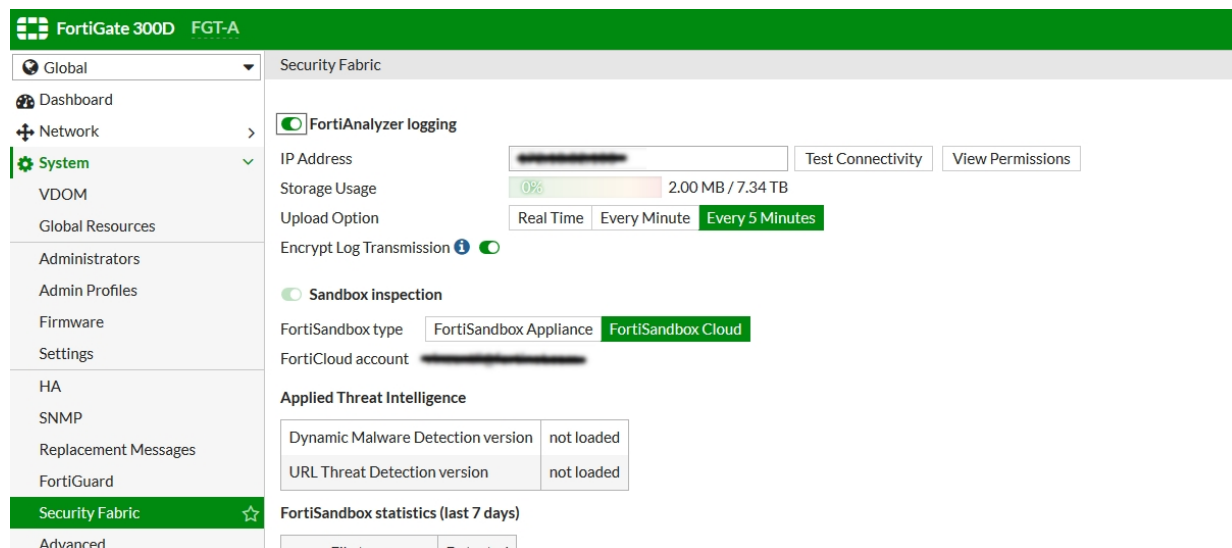

To receive updates to the Application Control signature database, you must have a valid FortiCare support contract.

## IPS / Application Control logging performance

There is a major boost to Application Control and IPS when logging is enabled. With the latest changes, the performance difference with or without logging enabled is negligible.

## Real time logging to FortiAnalyzer and FortiCloud

FortiOS 5.6.0 adds new real-time logging options for FortiAnalyzer in **System > Security Fabric** and for FortiCloud in **Log & Report > Log Settings**. The default option is still every 5 minutes, but this will allow near real-time uploading and consistent high-speed compression and analysis.

For FortiAnalyzer, the CLI syntax to enable real-time is:

```
config log fortianalyzer setting
  set upload-option [realtime/1-minute/5-minute]
```

For FortiCloud:

```
config log fortiguard setting
  set upload-option [realtime/1-minute/5-minute]
```

## Reliable Logging updated for real-time functionality (378937)

Previously, reliable logging was a feature for buffering and collecting logs for upload, to guarantee that no logs would be dropped before being passed to logging solutions. Reliable logging has been updated for 5.6.0 and is now enabled by default, so that real-time logs do not outpace upload speed.

It can be configured in the CLI with:

```
config log fortianalyzer setting
  set reliable [enable/disable]
```

## FortiGate Logs can be sent to syslog servers in Common Event Format (CEF) (300128)

You can configure FortiOS to send log messages to remote syslog servers in CEF format. CEF is an open log management standard that provides interoperability of security-related information between different network devices and applications. CEF data can be collected and aggregated for analysis by enterprise management or Security Information and Event Management (SIEM) systems such as FortiSIEM.

FortiOS supports logging to up to four remote syslog servers. Each server can now be configured separately to send log messages in CEF or CSV format. Previously only CSV format was supported.

Use the following command to configure syslog3 to use CEF format:

```
config log syslog3 setting
  set format cef
end
```

All other syslog settings can be configured as required independently of the log message format including the server address and transport (UDP or TCP). You can also configure filtering for both CEF and CSV formatted log messages.

## Controlled failover between wireless controllers

### 1+1 Wireless Controller HA

Instances of failover between FortiAP units was too long and lead to extended periods of time where WiFi users were without network connection. Because WiFi is considered a primary network connection in today's verticals (including enterprise, retail, education, warehousing, healthcare, government, and more), it is necessary for successful failover to occur as fast as possible.

### Primary and secondary ACs

You can now define the role of the primary and secondary controllers on the FortiAP unit, allowing the unit to decide the order in which the FortiAP selects the FortiGate. This process was previously decided on load-based detection, but can now be defined by each unit's pre-determined priority. In addition, heartbeat intervals have been lowered to further improve FortiAP awareness and successful failover.

### 1+1 redundancy

1+1 HA is a form of resilience whereby a component has a backup component to take its place in the event of component failure, and successfully manage FortiAP without long failover periods.

### CLI syntax

```
config wireless-controller inter-controller
  set inter-controller-mode {disable | l2-roaming | 1+1} Default is disable.
  set inter-controller-key <password>
  set inter-controller-pri {primary | secondary} Default is primary.
  set fast-failover-max [3-64] Default is 10.
  set fast-failover-wait [10-86400] Default is 10.
  config inter-controller-peer
    edit <name>
      set peer-ip <ip-address>
```

```

        set peer-port [1024-49150] Default is 5246.
        set peer-priority {primary | secondary} Default is primary.
    next
end
end

```

## Multiple PSK for WPA Personal (393320)

New CLI commands have been added, under `config wireless-controller vap`, to configure multiple WiFi Protected Access Pre-Shared Keys (WPA-PSKs), as PSK is more secure without all devices having to share the same PSK.

Note that `mpsk-concurrent-clients` and the `mpsk-key` configuration method are only available when `mpsk` is set to enable.

### CLI syntax

```

config wireless-controller vap
    edit <example>
        set mpsk {enable|disable}
        set mpsk-concurrent-clients [0-65535] Default is 0.
        config mpsk-key
            edit <key-name>
                set passphrase <wpa-psk>
                set concurrent-clients [0-65535] Default is empty.
                set comment <comments>
            next
        end
    end
end

```

Use the `mpsk-concurrent-clients` entry to set the maximum number of concurrent connected clients for each `mpsk` entry. Use the `mpsk-key` configuration method to configure multiple `mpsk` entries.

## Hotspot 2.0 (443988) - FortiOS 5.6.3

Multiple new CLI commands have been added, under `config wireless-controller`, to configure Hotspot 2.0 Access Network Query Protocol (ANQP), a query and response protocol that defines seamless roaming services offered by an AP.

### Syntax

```

config wireless-controller hotspot20 anqp-3gpp-cellular
    edit {name}
        config mcc-mnc-list
            edit {id}
                set id {integer}
                set mcc {string}
                set mnc {string}
            next
        next
    end

config wireless-controller hotspot20 anqp-ip-address-type
    edit {name}
        set ipv6-address-type {option}
        set ipv4-address-type {option}
    end

```

```
    next
end

config wireless-controller hotspot20 anqp-nai-realm
  edit {name}
    config nai-list
      edit {name}
        set encoding {enable | disable}
        set nai-realm {string}
        config eap-method
          edit {index}
            set index {integer}
            set method {option}
            config auth-param
              edit {index}
                set index {integer}
                set id {option}
                set val {option}
              next
            next
          next
        next
      next
    next
  next
end

config wireless-controller hotspot20 anqp-network-auth-type
  edit {name}
    set auth-type {option}
    set url {string}
  next
end

config wireless-controller hotspot20 anqp-roaming-consortium
  edit {name}
    config oi-list
      edit {index}
        set index {integer}
        set oi {string}
        set comment {string}
      next
    next
  next
end

config wireless-controller hotspot20 anqp-venue-name
  edit {name}
    config value-list
      edit {index}
        set index {integer}
        set lang {string}
        set value {string}
      next
    next
  next
end

config wireless-controller hotspot20 h2qp-conn-capability
  edit {name}
    set icmp-port {option}
    set ftp-port {option}
```

```
        set ssh-port {option}
        set http-port {option}
        set tls-port {option}
        set pptp-vpn-port {option}
        set voip-tcp-port {option}
        set voip-udp-port {option}
        set ikev2-port {option}
        set ikev2-xx-port {option}
        set esp-port {option}
    next
end

config wireless-controller hotspot20 h2qp-operator-name
    edit {name}
        config value-list
            edit {index}
                set index {integer}
                set lang {string}
                set value {string}
            next
        next
    end

config wireless-controller hotspot20 h2qp-osu-provider
    edit {name}
        config friendly-name
            edit {index}
                set index {integer}
                set lang {string}
                set friendly-name {string}
            next
        set server-uri {string}
        set osu-method {option}
        set osu-nai {string}
        config service-description
            edit {service-id}
                set service-id {integer}
                set lang {string}
                set service-description {string}
            next
        set icon {string}
    next
end

config wireless-controller hotspot20 h2qp-wan-metric
    edit {name}
        set link-status {option}
        set symmetric-wan-link {option}
        set link-at-capacity {enable | disable}
        set uplink-speed {integer}
        set downlink-speed {integer}
        set uplink-load {integer}
        set downlink-load {integer}
        set load-measurement-duration {integer}
    next
end
```

```
config wireless-controller hotspot20 hs-profile
edit {name}
    set access-network-type {option}
    set access-network-internet {enable | disable}
    set access-network-asra {enable | disable}
    set access-network-esr {enable | disable}
    set access-network-uesa {enable | disable}
    set venue-group {option}
    set venue-type {option}
    set hessid {mac address}
    set proxy-arp {enable | disable}
    set l2tif {enable | disable}
    set pame-bi {enable | disable}
    set anqp-domain-id {integer}
    set domain-name {string}
    set osu-ssid {string}
    set gas-comeback-delay {integer}
    set gas-fragmentation-limit {integer}
    set dgaf {enable | disable}
    set deauth-request-timeout {integer}
    set wnm-sleep-mode {enable | disable}
    set bss-transition {enable | disable}
    set venue-name {string}
    set roaming-consortium {string}
    set nai-realm {string}
    set oper-friendly-name {string}
    config osu-provider
        edit {name}
        next
    set wan-metrics {string}
    set network-auth {string}
    set 3gpp-plmn {string}
    set conn-cap {string}
    set qos-map {string}
    set ip-addr-type {string}
next
end

config wireless-controller hotspot20 icon
edit {name}
    config icon-list
        edit {name}
            set lang {string}
            set file {string}
            set type {option}
            set width {integer}
            set height {integer}
        next
    next
end

config wireless-controller hotspot20 qos-map
edit {name}
    config dscp-except
        edit {index}
            set index
            set dscp
```

```

        set up
      next
    config dscp-range
      edit {index}
        set index
        set up
        set low
        set high
      next
    next
  end

```

## VXLAN support (289354)

Virtual Extensible LAN (VXLAN) is a network virtualization technology used in large cloud computing deployments. It encapsulates OSI layer 2 Ethernet frames within layer 3 IP packets using standard destination port 4789. VXLAN endpoints that terminate VXLAN tunnels can be virtual or physical switch ports, are known as VXLAN tunnel endpoints (VTEPs). For more information about VXLAN, see [RFC 7348](#).

## VTEP (VXLAN Tunnel End Point) support (289354)

Native VXLAN is now supported by FortiOS. This feature is configurable from the CLI only:

### Syntax

```

config system vxlan
  edit <vxlan1> //VXLAN device name (Unique name in system.interface).
    set interface //Local outgoing interface.
    set vni //VXLAN network ID.
    set ip-version //IP version to use for VXLAN device (4 or 6).
    set dstport //VXLAN destination port, default is 4789.
    set ttl //VXLAN TTL.
    set remote-ip //Remote IP address of VXLAN.
  next
end

```

This will create a VXLAN interface:

```

show system interface vxlan1
config system interface
  edit "vxlan1"
    set vdom "root"
    set type vxlan
    set snmp-index 36
    set macaddr 8a:ee:1d:5d:ae:53
    set interface "port9"
  next
end

```

From the GUI, go to **Network > Interfaces** to verify the new VXLAN interface:

vxlan (1)				
	vxlan1	0.0.0.0.0.0.0	interface_type::vxlan	0

To diagnose your VXLAN configuration, from the CLI, use the following command:

```
diagnose sys vxlan fdb list vxlan1
```

This command provides information about the VXLAN forwarding data base (fdb) associated to the vxlan1 interface. Below is a sample output:

```
-----mac=00:00:00:00:00:00 state=0x0082 flags=0x00-----  
-----remote_ip=2.2.2.2 remote_port=4789-----  
-----remote_vni=1 remote_ifindex=19-----  
total fdb num: 1
```

### VXLAN support for multiple remote IPs (398959)

VXLAN is now supported for multiple remote IPs, these remote IPs can be IPv4 unicast, IPv6 unicast, IPv4 multicast, or IPv6 multicast. This is useful in datacenter scenarios where the FortiGate can be configured with multiple tunnels to computer nodes.

#### CLI changes

set ip-version option can be set to the following:

ipv4-unicast//Use IPv4 unicast addressing for VXLAN.

ipv6-unicast //Use IPv6 unicast addressing for VXLAN.

ipv4-multicast//Use IPv4 multicast addressing for VXLAN.

ipv6-multicast//Use IPv6 multicast addressing for VXLAN.

When ip-version is set to ipv4-multicast or ipv6-multicast, ttl option is replaced by multicast-ttl.

## New PPPoE features

### PPPoE dynamic gateway support (397628)

Original design for PPPoE requires to configure a static gateway. Although it works in many scenarios, some customers require to add support for dynamic gateway for internet-service based routes.

No changes to the CLI neither to the GUI.

### Support multiple PPPoE connections on a single interface (363958)

Multiple PPPoE connections on a single physical or vlan interface are now supported by the FortiGate. In addition the interface can be on demand PPPoE.

## CLI

```

config system pppoe-interface
edit <name>
set dial-on-demand [enable|disable]
set ipv6 [enable|disable]
set device <interface>
set username <string>
set password <string>
set auth-type [auto|pap|chap|mschapv1|mschapv2]
set ipunnumbered <class_ip>
set pppoe-unnumbered-negotiate [enable|disable]
set idle-timeout <integer>
set disc-retry-timeout <integer>
set padt-retry-timeout <integer>
set service-name <string>

```

```

set ac-name <string>
set lcp-echo-interval <integer>
set lcp-max-echo-fails <integer>

```

- dial-on-demand - Enable/disable the dial on demand feature
- ipv6 - Enable/disable the use of IPv6.
- device - The name of the physical interface.
- username - User name for credentials
- password - Password matching the above username
- auth-type - The type of PPP authentication to be used.
  - auto - Automatic choice of authentication
  - pap - PAP authentication
  - chap - CHAP authentication
  - mschapv1 - MS-CHAPv1 authentication
  - mschapv2 - MS-CHAPv2 authentication
- ipunnumbered - PPPoE unnumbered IP.
- pppoe-unnumbered-negotiate - Enable/disable PPPoE unnumbered negotiation.
- idle-timeout - Idle time in seconds before PPPoE auto disconnects. 0 (zero) for no timeout.
- disc-retry-timeout - Timeout value in seconds for PPPoE initial discovery. 0 to 4294967295. Default = 1.
- padt-retry-timeout - Timeout value in seconds for PPPoE termination. 0 to 4294967295. Default = 1.
- service-name - PPPoE service name.)
- ac-name - PPPoE AC name.
- lcp-echo-interval - Interval in seconds allowed for PPPoE LCP echo. 0 to 4294967295. Default = 5.
- lcp-max-echo-fails - Maximum number of missed LCP echo messages before disconnect. 0 to 4294967295. Default = 3.

## Adding Internet services to firewall policies (389951)

In 5.4, support was added for Internet Service objects which could be used with **FortiView**, **Logging**, **Routing** and **WAN Load Balancing**. Now they can be added to firewall policies as well.

There is an either/or relationship between Internet Service objects and destination address and service combinations in firewall policies. This means that a destination address and service can be specified in the policy OR an Internet service, not both.

## CLI

The related CLI options/syntax are:

```

config firewall policy
edit 1
set internet-service 1 5 10
set internet-service-custom test
set internet-service-negate [enable|disable]
end

```

## GUI

In the policy listing page you will notice that is an Internet Service object is used, it will be found in both the **Destination** and **Service** column.

In the policy editing page the **Destination Address**, now **Destination** field now has two types, **Address** and **Internet Service**.

## Combining source and destination NAT in the same policy (388718)

The Service field has been added to Virtual IP objects. When `service` and `portforward` are configured, only a single mapped port can be configured. However, multiple external ports can be mapped to that single internal port.

```
config firewall vip
  edit "vip1"
    set type load-balance
    set service "HTTP-8080" "HTTP" <----- New Service field, accepts Service/Service
    group names
    set extip 20.0.0.0-20.0.255.255
    set extintf "wan1"
    set portforward enable
    set mappedip "30.0.0.1"
    set mappedport 100 <----- single port
  end
```

The reason for making this configuration possible is to allow complex scenarios where multiple sources of traffic are using multiple services to connect to a single computer, while requiring a combination of source and destination NAT and not requiring numerous VIPs bundled into VIP groups.

VIPs with different services will considered non-overlapping.

Name	<input type="text" value="Service-VIP"/>		
Comments	<input type="text"/>	0/255	
<b>Network</b>			
Interface	<input type="checkbox"/> any ▼		
Type	Static NAT

## NP6 Host Protection Engine (HPE) adds protection for DDoS attacks (363398)

NP6 processors now include HPE functionality that can protect networks from DoS attacks by categorizing incoming packets based on packet rate and processing cost and applying packet shaping to packets that can cause DoS attacks. You can use the options in the following CLI command to limit the number packets per second received for various packet types by each NP6 processor. This rate limiting is applied very efficiently because it is done in hardware by the NP6 processor.

HPE protection is disabled by default. You can use the following command to enable HPE protection for the NP6\_0 NP6 processor:

```
config system np6
  edit np6_0
    config hpe
      set enable-shaper enable
    end
```

HPE can be enabled and configured separately for each NP6 processor. When enabled, the default configuration is designed to provide basic DoS protection. You can use the following command to adjust the HPE settings in real time if your network is experiencing an attack. For example, the following command allows you to configure HPE settings for np6\_0.

```
config system np6
  edit np6_0
    config hpe
      set tcpsyn-max
```

```

set tcp-max
set udp-max
set icmp-max
set sctp-max
set esp-max
set ip-frag-max
set ip-others-max
set arp-max
set l2-others-max
set enable-shaper {disable | enable}
end

```

**Where:**

`tcpsyn-max` applies shaping based on the maximum number of TCP SYN packets received per second. The range is 10,000 to 4,000,000,000 pps. The default limits the number of packets per second to 5,000,000 pps.

`tcp-max` applies shaping based on the maximum number of TCP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 5,000,000 pps.

`udp-max` applies shaping based on the maximum number of UDP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 5,000,000 pps.

`icmp-max` applies shaping based on the maximum number of ICMP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 1,000,000 pps.

`sctp-max` applies shaping based on the maximum number of SCTP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.

`esp-max` NPU HPE shaping based on the maximum number of IPsec ESP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.

`ip-frag-max` applies shaping based on the maximum number of fragmented IP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.

`ip-others-max` applies shaping based on the maximum number of other IP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.

`arp-max` applies shaping based on the maximum number of ARP packets received. The range is 10,000 to 4,000,000,000 pps. The default is 1,000,000 pps.

`l2-others-max` applies shaping based on the maximum number of other layer 2 packets received. The range is 10,000 to 4,000,000,000 pps. The default is 100,000 pps.

## New feature catalog (5.6.3, 5.6.1 and 5.6)

The following sections list all of the new features in FortiOS 5.6, 5.6.1, and 5.6.3 organized alphabetically by subject area.

### Getting Started (5.6.3)

New Getting Started features added to FortiOS 5.6.3.

### Administrator password changes (414927)

The existing Change Password dialog that appears in the GUI is updated to reflect the new look of the password change prompt at login.

- Added inline validation for checking password policy and password reuse
- Changed style to match new login prompt password change
- Fixed issue where fDialog would close slide out on submission failure

### Support FortiOS to allow user to select domain when logging a FG into FortiCloud (452350)

Support has been added to show a list of all possible FortiCloud domains that the FortiGate can be served by.

#### Syntax

```
execute fortiguard-log domain
```

This command is typically used for testing purposes, and so it will not appear when entering `execute fortiguard-log ?`.

## Getting Started (5.6.1)

New Getting Started features added to FortiOS 5.6.1.

### VM License visibility improvement (423347)

VM License GUI items have changed as follows:

- Added VM widget to **Global > Dashboard**. Includes the following:
  - License status and type.
  - CPU allocation usage.
  - License RAM usage.
  - VMX license information (if the VM supports VMX).
  - If the VM license specifies 'unlimited' the progress bar is blank.
  - If the VM is in evaluation mode, it is yellow (warning style) and the dashboard show evaluation days used.
- Widget is shown by default in the dashboard of a FortiOS VM device.
- Removed VM information from License widget at **Global > Dashboard**.
- License info and **Upload License** button provided on page **Global > System > FortiGuard**.
- Updated 'Upload VM License' page:
  - Added license RAM usage and VMX instance usage.
  - Replaced file input component.

#### CLI Syntax

```
config sys admin
  edit <name>
    config gui-dashboard
      edit <1>
        set name <name>
        config widget
          edit <2>
```

```

        set type {vminfo | ...} <- new option
        set x-pos <2>
        set y-pos <1>
        set width <1>
        set height <1>
    next
end
next
end
next
end

```

## FortiView Dashboard Widget (434179)

Added a new widget type to the dashboard for top level FortiView. FortiView widgets have report-by, sort-by, visualization, timeframe properties, and filters subtable in the CLI.

Supported FortiViews include Source, Destination, Application, Country, Interfaces, Policy, Wifi Client, Traffic Shaper, Endpoint Vulnerability, Cloud User, Threats, VPN, Websites, and Admin and System Events.

Bubble, table, chord chart, and country visualizations are supported in the widget.

Widgets can be saved from a filtered FortiView page on to a dashboard.

### Syntax

```

config system admin
  config gui-dashboard
    config widget
      set type fortiview
      set report-by {source | destination | country | intfpair | srcintf | dstintf |
        policy | wificlient | shaper | endpoint | application | cloud | web | threat
        | system | unauth | admin | vpn}
      set timeframe {realtime | 5min | hour | day | week}
      set sort-by <string>
      set visualization {table | bubble | country | chord}
      config filters
        set key <filter_key>
        set value <filter_value>
      end
    end
  end
end
end

```

Where:

- `report-by` = Field to aggregate the data by.
- `timeframe` = Timeframe period of reported data.
- `sort-by` = Field to sort the data by.
- `visualization` = Visualization to use.

## Controls added to GUI CLI console (422623)

FortiOS 5.6.1 introduces new options in the browser CLI console to export the console history. Options are now available to **Clear console**, **Download**, and **Copy to clipboard**.

The image shows a header bar for the 'CLI Console'. On the left, the text 'CLI Console' is displayed. On the right, there is a row of five icons: a trash can, a download arrow, a document with a plus sign, a square icon, and a close 'X' icon. A red rectangular box highlights the first three icons (trash, download, and document).

### FortiExplorer icon enhancement (423838)

FortiOS icons and colors are now exportable in the GUI shared project and FortiExplorer now uses these icons and colors. This change improves the icon colors only for the FortiExplorer GUI theme (seen only when accessing a web GUI page from within the FortiExplorer iOS app).

The following locations were affected: Policy List, Policy Dialogue, Address List, Address Dialogue, Virtual IP list, Virtual IP Dialogue.

## Getting Started (5.6)

New Getting Started features added to FortiOS 5.6.

### Change to CLI console (396225)

The CLI Console widget has been removed from FortiOS 5.6.0. It is accessed from the upper-right hand corner of the screen and is no longer a pop-out window but a sliding window.

### System Information Dashboard widget WAN IP Information enhancement (401464)

WAN IP and location data are now available in the **System Information** widget. Additionally, If the WAN IP is blacklisted in the FortiGuard server, there will be a notification in the notification area, located in the upper right-hand corner of the **Dashboard**. Clicking on the notification will open the WAN IP Blacklisted slider with the relevant blacklist information.

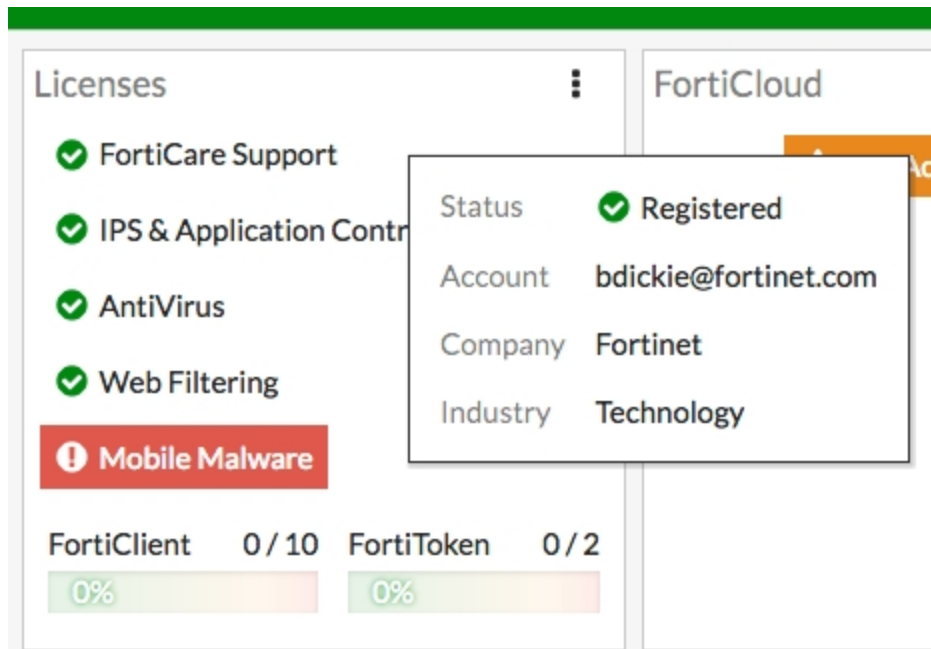

### CLI and GUI changes to display FortiCare registration information (395254)

The changes pertain to industry and organization size of the FortiGate's registered owner.

#### GUI Changes

- Add industry and organization size to FortiCare registration page
- Add company and industry to license widget tooltip for FortiCare

When you hover over the Licenses widget in the FortiOS 5.6 dashboard, you can see the company and industry data, provided it has been entered in the FortiCare profile.

## CLI Changes

Commands are added to diagnose forticare

```

dia forticare direct-registration product-registration -h
Options: a:A:y:C:c:T:eF:f:hI:i:l:O:o:p:P:z:R:r:S:s:t:v:

```

### **Improved GUI for Mobile Screen Size & Touch Interface (355558)**

The FortiOS web GUI on mobile screens and include functionality for touch interfaces like tap to hold are improved.

### **Setup Wizard removed**

Previously, the Setup Wizard could be launched from the web GUI by selecting the  button, located in the top right corner. This button and the wizard in question has been removed.

## Authentication (5.6.3)

New authentication features added to FortiOS 5.6.3.

### Certificate Import page updates (267949)

The importation of a non-CA certificate into FortiGate CA store now shows a warning message showing why the import didn't work (as expected).

### Improvements to the execute fortitoken import command (401979)

The `execute fortitoken import` command has been removed and replaced by three new commands, allowing the importation of FortiToken seed files from either an FTP server, a TFTP server, or a USB drive:

- `execute fortitoken import ftp <file name> <ip>[:ftp port] <Enter> <user> <password>`
- `execute fortitoken import tftp <file name> <ip>`
- `execute fortitoken import usb <file name>`

These commands allow seed files to be imported from an external source more easily.

### Improved 2FA workflow in GUI (405487, 409100, 444430, 446856, 456752)

Various improvements to the two-factor authentication workflow in the GUI which addressed the following issues:

- No email was sent after creating an administrator account with a FortiToken.
- Inconsistent view on admin and user dialog.
- Empty activation codes would be sent.
- If Norway was selected as the country code for a user, the phone number was not recognized after saving.
- Couldn't select custom SMS server when setting the phone number.
- When a FortiToken from a non-management VDOM was selected for an admin, the activation code wouldn't be sent.

### Support FTM Push when FortiAuthenticator is the authentication server (408273, 438314)

FortiGate supports when the FortiAuthenticator initiates FTM Push notifications, for when users are attempting to authenticate through a VPN and/or RADIUS (with FortiAuthenticator as the RADIUS server).

### Support exact match for subject and CN fields in peer user (416359)

Administrators can now specify which way a peer user authenticates, in order to avoid any unintentional admin access by a regular user. When searching for a matching certificate, use the commands below to control how to find matches in the certificate subject name (`subject-match`) or the cn attribute (`cn-match`) of the certificate subject name. This match can be any string (`substring`) or an exact match (`value`) of the cn attribute value.

#### Syntax

```
config vpn certificate setting
  edit <name>
    set subject-match {substring | value}
    set cn-match {substring | value}
  next
end
```

### FortiToken GUI improvement (435229)

Various FortiToken import functionalities have been improved in the GUI, including the ability to import from serial number file correctly, validation of serial numbers once imported, and removing the Activate button once a token has already been activated.

### Improve FTM Push notification workflow (436642, 448734)

Updated GUI and logincheck module to use a non-blocking version of the FTM Push notification procedure and periodically polls the device for any status updates from fam daemon.

### FortiClient shares Social ID data with FortiOS (438610)

Support has been added to record the social ID data from FortiClient so that if an email or phone number is changed on FortiClient, the new values are updated on the FortiGate.

The data will be sent in KeepAlive messages in the following format:

```
USR_NAME|<full name for the service account>|USR_EMAIL|<email for the service account>|SERVICE|<os|custom|linkedin|google|salesforce>|
```

### Wildcard certificate support/handling for SAN/CN reference identifiers (440307)

As a requirement of Network Device Collaborative Protection Profile (NDcPP), FortiOS supports and handles the use of wildcards for the following certificate reference parameters:

- Subject Alternative Name (SAN)
- Common Name (CN)

### Support for FTP and TFTP to update certificates (441695)

Support has been added for FTP and TFTP servers to update the certificate bundle using a new `execute` command.

#### Syntax

```
execute vpn certificate ca import bundle <file-name.pkg> <ftp/tftp-server-ip>
```

### Global option to enable/disable SHA1 algorithm in SSH key exchanges (444827)

Support has been added for a global option to enable/disable SHA1 algorithm in SSH key exchanges. The algorithm is enabled by default and provides administrators with the ability to disable the option for the purposes of security and compliance testing.

#### Syntax

```
config system global
    set ssh-kex-sha1 {enable | disable}
end
```

### Support for HTTP tunnel authentication (449406)

Support has been added for an option to trigger user authentication on HTTP CONNECT request at the policy level. A new CLI entry has been added under `config firewall proxy-policy` which will trigger the

authentication process get-user, even when there is no user or group configured.

Note that, as shown below, explicit web proxy must be set.

### Syntax

```
config firewall proxy-policy
  edit {policyid}
    set proxy explicit-web
    set http-tunnel-auth {enable | disable}
  next
end
```

## Authentication (5.6.1)

New authentication features added to FortiOS 5.6.1.

### IPv6 RADIUS Support (309235, 402437, 439773)

RADIUS authentication is supported with IPv6, allowing administrators to configure an IPv6 RADIUS server on the FortiGate for IPv6 RADIUS authentication traffic to pass between the server and FortiGate.

Note that while you can set the primary RADIUS server's IPv6 address, the source IP address for communications to the RADIUS server cannot be configured as IPv6.

### Syntax

Allow IPv6 access on an interface:

```
config system interface
  edit <name>
    config ipv6
      set ip6-allowaccess {ping | https | ssh | snmp | http | telnet | fgfm | capwap}
      set ip6-address <xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx/xxx>
    next
  next
end
```

Configure the IPv6 RADIUS server:

```
config user radius
  edit <name>
    set server <xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx>
    ...
  next
end
```

### Full certificate chain CRL checking (407988)

Certificate revocation/status check for peer certificates and intermediate CAs is now supported. Redesigned fnbam\_auth\_cert() API to use stack type of X509 instead of array for certificate chain. Removed obsolete fnbam API and parameters. Now authd, sslvnd, and GUI send full certificate chains to fnbamd for verification.

### New option under user > setting to allow/forbid SSL renegotiation in firewall authentication (386595)

A new option `auth-ssl-allow-renegotiation` is now available under `config user setting` to allow/forbid renegotiation. The default value is `disable`, where a session would be terminated by `authd` once renegotiation is detected and this login would be recorded as failure. Other behavior follows regular auth settings.

#### Syntax

```
config user setting
    set auth-ssl-allow-renegotiation {enable | disable}
end
```

### New option to allow spaces in RADIUS DN format (422978)

Previously, IKEv2 RADIUS group authentication introduced a regression because it removed spaces from ASN.1 DN peer identifier string.

Reverted default DN format to include spaces. Added a new CLI option `ike-dn-format` to allow the user to select either `with-space` or `no-space`. Customers using the `group-authentication` option can select the `ike-dn-format` setting to match the format used in their RADIUS user database.

### Added LDAP filter when group-member-check is user-attr (403140)

Added LDAP filter when `group-member-check` is `user-attr`. LDAP filter is deployed when checking user attribute.

#### Syntax

```
config user ldap
    edit <name>
        set group-filter ?
    next
end
```

- `group-filter` is `none` by default, where the process is the same as before. When `group-filter` is set, the LDAP filter takes effect for retrieving the group information.

### Added Refresh button to the LDAP browser (416649)

Previously, cached LDAP data was used even if the LDAP server configuration was updated.

In FortiOS 5.6.1, a **Refresh** button has been added in the LDAP browser. In the LDAP server dialog page, the user can delete the DN field to browse the root level tree when clicking the **Fetch DN** button.

### Differentiate DN option for user authentication and membership searching (435791)

Previously, LDAP used the same DN option for user authentication and membership searching. New CLI commands are introduced to `config user ldap` to resolve this issue:

- `group-member-check user-attr`  
For user attribute checking, a new attribute `group-search-base` is added, which indicates the starting point for the group search. If the `group-search-base` is not set, `binddn` is used as the search base. Removed `search-type` when `group-member-check` is `user-attr`.

- `group-member-check group-object`  
For group object checking, the group names in user group match rule will be picked up as the group search base. If there are multiple matching rules, each group name will trigger the ldapsearch query once.
- `group-member-check posix-group-object`  
Changed `group-object-search-base` to `group-search-base` for `posix-group-object group-member-check`.

### FTM Push when FAC is auth server (408273)

This feature adds support for FortiToken Mobile (FTM) push with FortiAuthenticator server in FortiOS. It also fixes a crash when adding a node to an RB tree, by checking if the same key has already been used in the tree. If yes, remove the node using the same key before adding a new node.

### Non-blocking LDAP authentication (433700)

The previous LDAP authentication in `fnbamd` used `openldap` library. OpenLDAP supports non-blocking BIND but it is not event driven.

To support non-blocking LDAP in `fnbamd`, we stopped using the `openLDAP` library in `fnbamd`, instead using only `liblber`. Instead of using `openLDAP`, `fnbamd` will create its own event-driven connection with LDAP servers over LDAP/LDAPS/STARTTLS, make it non-blocking, do CRL checking if necessary, and compose all LDAP requests using `liblber` (including bind, unbind, search, password renewal, password query, send request and receive response, and parse response). The whole process is done in one connection.

This doesn't change any `openLDAP` implementation but moves some data structure definitions and API definitions from some internal header files to public header files.

### Manual certificate SCEP renewal (423997)

Added support of manual certificate SCEP renewal besides the auto-regeneration feature that already exists.

### More detailed RADIUS responses shown in connectivity test (434303)

Improved on-demand test connectivity for RADIUS servers. Test results show RADIUS server reachability, NAS client rejection, and invalid User/Password. Test also shows RADIUS Attributes returned from the RADIUS server.

#### Example

```
FG100D3G12807101 # diagnose test authserver radius-direct
<server_name or IP> <port no(0 default port)> <secret> <user> <password>

FG100D3G12807101 # diagnose test authserver radius-direct 1.1.1.1 0 dd
RADIUS server '1.1.1.1' status is Server unreachable

FG100D3G12807101 # diagnose test authserver radius-direct 172.18.5.28 0 dd
RADIUS server '172.18.5.28' status is Secret invalid

FG100D3G12807101 # diagnose test authserver radius-direct 172.18.5.28 0 fortinet jeff1
asdfasdf
RADIUS server '172.18.5.28' status is OK
Access-Reject

FG100D3G12807101 # diagnose test authserver radius-direct 172.18.5.28 0 fortinet ychen1
asdfasdf
```

```

RADIUS server '172.18.5.28' status is OK
Access-Accept
AVP: l=6 t=Framed-Protocol(7)
  Value: 1
AVP: l=6 t=Service-Type(6)
  Value: 2
AVP: l=46 t=Class(25)
  Value: 9e 2a 08 6d 00 00 01 37 00 01 17 00 fe 80 00 00 00 00 00 00 00 00 5e fe ac 12 05
      1c 01 d2 cd b6 75 a6 80 56 00 00 00 00 00 00 00 1c
AVP: l=12 t=Vendor-Specific(26) v=Microsoft(311)
  VSA: l=6 t=MS-Link-Utilization-Threshold(14)
    Value: 50
AVP: l=12 t=Vendor-Specific(26) v=Microsoft(311)
  VSA: l=6 t=MS-Link-Drop-Time-Limit(15)
    Value: 120

```

### User group authentication timeout range increased to 30 days (378085)

You can now use the following command to override the default user authentication timeout for users in a user group to up to 30 days.

```

config user group
  edit <group-name>
    set authtimeout 43200
  end

```

Where `authtimeout` is the length of the timeout in minutes. An `authtimeout` of 43200 minutes is equivalent to 30 days. Set `authtimeout` to 0 to use the default authentication timeout.

## Authentication (5.6)

New authentication features added to FortiOS 5.6.

### FortiToken Mobile Push (397912, 408273, 399839, 404872)

FortiToken Mobile push supports two-factor authentication without requiring users to enter a four-digit code to authenticate. Instead they can just accept the authentication request from their FortiToken Mobile app.

A new command has been added under `config system ftm-push` allowing you to configure the FortiToken Mobile Push services server IP address and port number. The Push service is provided by Apple (APNS) and Google (GCM) for iPhone and Android smartphones respectively. This will help to avoid tokens becoming locked after an already enabled two-factor authentication user has been disabled.

#### CLI syntax

```

config system ftm-push
  set server-ip <ip-address>
  set server-port [1-65535] Default is 4433.
end

```

If an SSL VPN user authenticates with their token, then logs out and attempts to reauthenticate again within a minute, a new message will display showing "Please wait x seconds to login again." This replaces a previous error/permission denied message.

The "x" value will depend on the calculation of how much time is left in the current time step.

### CLI syntax

```
config system interface
  edit <name>
    set allowaccess ftm
  next
end
```

### Support V4 BIOS certificate (392960)

FortiOS now supports backwards compatibility between new BIOS version 4 and old BIOS version 3.

#### New BIOS V4 certificates:

- Fortinet\_CA
- Fortinet\_Sub\_CA
- Fortinet\_Factory

#### Old BIOS V3 certificates:

- Fortinet\_CA\_Backup
- Fortinet\_Factory\_Backup

When FortiOS connects to FortiGuard, FortiCloud, FortiManager, FortiAnalyzer, FortiSandbox as a client, the new BIOS certificate **Fortinet\_Factory** will be the default client certificate. When the server returns its certificate (chain) back, FortiOS looks up the issuer of the server certificate and either keeps client certificate as is or switches to the old BIOS certificate **Fortinet\_Factory\_Backup**. This process occurs in one handshake.

When FortiOS connects to FortiCare, the new BIOS certificate **Fortinet\_Factory** is the only client certificate and Server Name Indication (SNI) is set. There is no switchover of certificate during SSL handshake.

When FortiOS acts as a server when connected by FortiExtender, FortiSwitch, FortiAP, etc., **Fortinet\_Factory** is the default server certificate. FortiOS detects SNI in client hello, and if no SNI is found or if the CN in SNI is different from the CN of **Fortinet\_CA**, it switches to use the old **Fortinet\_Factory\_Backup**.

### Support extendedKeyUsage for x.509 certificates (390393)

As per Network Device Collaborative Protection Profile (NDcPP) v1.0 requirements, server certificates used for TLS connections between FortiGate and FortiAnalyzer should have the "Server Authentication" and "Client Authentication" extendedKeyUsage fields in FIPS/CC mode.

To implement this, a new CLI command has been added under `log fortianalyzer setting` to allow you to specify the certificate used to communicate with FortiAnalyzer.

### CLI syntax

```
config log fortianalyzer setting
  set certificate <name>
end
```

### Administrator name added to system event log (386395)

The administrator's name now appears in the system event log when the admin issues a user quarantine ban on a source address.

### Support RSA-4096 bit key-length generation (380278)

In anticipation of quantum computers, RSA-4096 bit key-length CSRs can now be imported.

### New commands added to config user ldap to set UPN processing method and filter name (383561)

Added two new commands to `config user ldap` allowing you to keep or strip domain string of UPN in the token as well as the search name for this kind of UPN.

#### CLI syntax:

```
config user ldap
    set account-key-processing
    set account-key-name
end
```

### User authentication max timeout setting change (378085)

To accommodate wireless hotspot users authenticated on the FortiGate, the user authentication max timeout setting has been extended to three days (from one day, previously).

### Changes to Authentication Settings > Certificates GUI (374980)

Added new icons for certificate types and updated formatters to use these new icons.

### Password for private key configurable in both GUI and CLI (374593)

FortiOS 5.4.1 introduced a feature that allowed you to export a local certificate and its private key in password protected p12, and later import them to any device. This option to set password for private key was available only in the CLI (when requesting a new certificate via SCEP or generating a CSR). This feature is now also configurable through the GUI.

The new **Password for private key** option is available under **System > Certificates** when generating a new CSR.

### RADIUS password encoding (365145)

A new CLI command, under `config user radius`, has been added to allow you to configure RADIUS password encoding to use ISO-8859-1 (as per [RFC 2865](#)).

Certain RADIUS servers use ISO-8859-1 password encoding instead of others such as UTF-8. In these instances, the server will fail to authenticate the user, if the user's password is using UTF-8.

#### CLI syntax

```
config user radius
    edit <example>
        set password-encoding <auto | ISO-8859-1>
    end
```

This option will be skipped if the `auth-type` is neither `auto` nor `pap`.

### RSSO supports Delegated-IPv6-Prefix and Framed-IPv6-Prefix (290990)

Two attributes, **Delegated-IPv6-Prefix** and **Framed-IPv6-Prefix**, have been introduced for RSSO to provide a /56 prefix for DSL customers. All devices connected from the same location (/56 per subscriber) can be mapped to the same profile without the need to create multiple /64 or smaller entries.

## FortiOS Carrier (5.6.3)

New FortiOS Carrier features added to FortiOS 5.6.3.

### Improved CLI attribute name under 'gtp.message-filter-v0v1' (452813)

CLI "gtp.message-filter-v0v1" had an attribute "create-aa-pdp|init-pdp-ctx", which contains a vertical pipe |. The attribute name was changed to "v0-create-aa-pdp--v1-init-pdp-ctx".

Its help text is also changed to avoid the vertical bar.

#### Syntax

```
config gtp message-filter-v0v1
edit <name>
set ?
.....
v0-create-aa-pdp--v1-init-pdp-ctx
```

### Improved GTP performance (423332)

There are independent Receive and Transmit queues for `gtp-u` process. These queues are and their associated resources are initialized when the `ftp-enhance-mode` is enabled.

### CLI changes under system npu

#### gtp-enhance-mode

```
config system npu
set gtp-enhance-mode [enable|disable]
end
```

This configuration requires a reboot of the device to initialize the changes.

---

#### gtp-enhance-cpu-range

This is used to set the CPUs which can process the GTP-U packet inspection.

```
config system npu
set gtp-enhance-cpu-range [0|1|2]
end
```

Option	Description
0	Inspect GTPU packets by all CPUs
1	Inspect GTPU packets by Master CPUs
2	Inspect GTPU packets by Slave CPUs

### New diagnose commands

```
diagnose npu np6 hbq-stats [all|np xx]
```

Used to see the GTP-U packet counter by all NP or the corresponding np.

```
diagnose npu np6 hbq-stats-clear all /np xx
```

Used to clear the GTP-U packet counter by all NP or the corresponding np.

### Verifying the enhance-mode is disabled

Before execute the test or enable/disable the gtp enhance, first check the gtp-enhance-mode status as in the example below:

```
config system npu
  get
  gtp-enhance-mode: disable
  gtp-enhance-cpu-range: 0
end
```

If the gtp-enhance-mode is disable, use the command `diagnose npu np6 hbq-stats all`.

The output will be similar to below:

```
# diagnose npu np6 hbq-stats all
Total :0
```

If the gtp-enhance-mode is enable, use the command `diagnose npu np6 hbq-stats all`

The output will be similar to below:

```
# diagnose npu np6 hbq-stats all
cpu_ 0:0
cpu_ 1:0
cpu_ 2:0
cpu_ 3:0
cpu_ 4:0
cpu_ 5:0
cpu_ 6:0
cpu_ 7:0
cpu_ 8:0
cpu_ 9:0
cpu_10:0
cpu_11:0
cpu_12:0
cpu_13:0
cpu_14:0
cpu_15:0
```

```
cpu_16:0
cpu_17:0
cpu_18:0
cpu_19:0
cpu_20:0
cpu_21:0
cpu_22:0
cpu_23:0
cpu_24:0
cpu_25:0
cpu_26:0
cpu_27:0
cpu_28:0
cpu_29:0
cpu_30:0
cpu_31:0
cpu_32:0
cpu_33:0
cpu_34:0
cpu_35:0
cpu_36:0
cpu_37:0
cpu_38:0
cpu_39:0
Total :0
```

Sometimes, when loading the new configure file, and the new configure file does not match the old configure file, the `gtp-enhance-mode` status will be confused.

You can see :

```
#config system npu
#get
gtp-enhance-mode: enable
```

but you can also see that

```
diagnose npu np6 hbq-stats all
Total :0
```

This means the `gtp-enhance-mode` is actually set to `disable`.

The inverse is also possible, when you see

```
#config system npu
#get
gtp-enhance-mode: disable
```

but you also see that

```
# diagnose npu np6 hbq-stats all
cpu_ 0:0
...
cpu_39:0
Total :0
```

This means the `gtp-enhance-mode` is actually set to `enable`.

If these combinations occur, just run the command below:

```
config system npu
  set gtp-enhance-mode enable
end
```

or

```
config system npu
  set gtp-enhance-mode disable
end
```

Once this is done, reboot the device to let the 2 statuses match.

## FortiOS Carrier (5.6.1)

New FortiOS Carrier features added to FortiOS 5.6.1.

### GTP enhancement and GTP Performance Improvement. (423332)

The GTP changes in 5.6.1 take place in the following categories:

#### New GTP features and functionality enhancements.

- GTP message filter enhancements, including:
  - Unknown message white list
  - GTPv1 and GTPv2 profile separation
  - Message adoption.
- GTP IE white list.
- Global APN rate limit, including:
  - sending back REJECT message with back-off timer
  - "APN congestion" cause value
- GTP half-open, half-close configurable timer.

#### GTP performance improvements.

- Implemented RCU on GTP-U running path. i.e, no locking needed to look up tunnel state when processing GTP-U.

**Note** the RCU is only applied on GTPv1 and GTPv2 tunnels. It is not used for GTPv0 tunnels, due to the fact that (1) GTPv0 traffic is relatively minor compared with GTPv1 and GTPv2, and (2) GTPv0 tunnel indexing is totally different from GTPv1 and GTPv2. GTPv0 tunnel is indexed by [IMSI, NSAPI]. GTPv1 and GTPv2 tunnel is indexed by [IP, TEID]

- Localized CPU memory usage on GTP-U running path.
- GTP-C: changed some GTP tables from RB tree to hash table, including
  - GTP request tables, and GTPv0 tunnel tables.
  - Testing showed, when handling millions of entries adding/deleting, hash table performance was much better.
  - 2.3.2 Hash table is compatible with RCU API, so we can apply RCU on these GTP-C tables later for further performance improvements.
- GTP-C, improved GTP path management logic, so that GTP path will time out sooner when there are no tunnels linked to it

**CLI Changes:****New Diagnose commands:**

```
diagnose firewall gtp
```

Option	Description
hash-stat-tunnel	GTP tunnel hash statistics.
hash-stat-v0tunnel	GTPv0 tunnel hash statistics.
hash-stat-path	GTP path hash statistics.
hash-stat-req	GTP request hash statistics.
vd-apn-shaper	APN shaper on VDOM level.
ie-white-list-v0v1	IE white list for GTPv0 or v1.
ie-white-list-v2	IE white list for GTPv2.

```
diagnose firewall gtp vd-apn-shaper
```

Option	Description
list	List

```
diagnose firewall gtp ie-white-list-v0v1
```

Option	Description
list	List

```
diagnose firewall gtp ie-white-list-v2
```

Option	Description
list	List

```
config gtp apn-shaperapn-shaper
```

Option	Description
apn	APN to match. Leave empty to match ANY.  "apn" field can be empty, it matches ANY apn. when configured, it is used to set a limit for any apn which is not explicitly listed; Also, if configured, such an entry should be the last entry, as it is first-match rule.
rate-limit	Rate limit in packets/s (0 - 1000000, 0 means unlimited).
action	Action. [drop   reject]  There is no back-off timer in GTPv0, therefor the <code>reject</code> action is not available for V0
back-off-time	Back off time in seconds (10 - 360).  <code>back-off-time</code> visible when action is "reject"

**Changed commands:**

Under command `firewall gtp,config message-filter` is replaced by `set message-filter-v0v1`

**Example:**

```
config firewall gtp
edit <name>
set message-filter-v0v1
```

New fields have been added to the `config firewall gtp` command context

Option	Description
half-open-timeout	Half-open tunnel timeout (in seconds).
half-close-timeout	Half-close tunnel timeout (in seconds).

**Example:**

```
config firewall gtp
edit <name>
set half-open-timeout 10
set half-close-timeout 10
```

**Models affected by change**

- FortiGate 3700D
- FortiGate 3700DX
- FortiGate 3800D

## Device identification (5.6)

New Device Identification features added to FortiOS 5.6.

### Changed default for device-identification-active-scan to disabled (380837)

It was decided that most customers would not appreciate a default setting that resulted in the FortiGate probing their systems, so active scan option is changed to disabled by default going forward, but upgrade code is added to keep the option enabled for those upgrading from 5.4.0 or 5.4.1 who were using device-identification with active scan enabled.

## Diagnose command changes (5.6.1)

New diagnose features added to FortiOS 5.6.1.

### crash dump improvement on i386/X86\_64 (396580)

The output from the WPAD crash dump can now be in binary format as well as hexadecimal. The two commands are:

1. For dump in binary format

```
diagnose debug app wpad-dump <debug_level>
```

2. For dump in hexadecimal format

```
diagnose debug app wpad-crash-hexdump <debug_level>
```

### LLDP diagnose commands easier to execute (413102)

While there is no change to the syntax of the commands, the LLDP diagnose commands are allowed to execute without switchid/portid parameters configured.

### New command to monitor IPS stats (414496)

When WAD IPS scanning took place with a failed result, the message caused the IPS sensor to mistakenly record the event as something triggering the sensor. To correct this, a new command was created.

#### Command:

```
diagnose wad stats ips [list | clear ]
```

list	List IPS statistics
clear	Clear IPS statistics

#### Example

```
diagnose wad stats ips list
IPS status
unix stream counter = 0
active sess counter = 0
ips provider counter = 0
not running failure = 0
all busy failure = 0
conn close counter = 0
conn connected counter = 0
conn failure = 0
zero len failure = 0
suspended failure = 0
push failure = 0
block write counter = 0
un-block write counter = 0
```

```

un-matching failure = 0
ips action failure = 0
ips action permit = 0
ips action deny = 0
ips action bypass = 0

```

### Additional information in FortiGate 30E model diagnose command (422266)

Due to additional modem features being merged into the FortiGate 30E firmware, there is more status information displayed when using the `diagnose sys lte-modem` command. There are also additional related MIB options.

### New diagnose sys fips kat-error options (440186)

The command `diagnose sys fips kat-error` has added additional options, like ECDSA.

## Diagnose command changes (5.6)

New diagnose features added to FortiOS 5.6.

### Add missing "diag npc np6 ..." Commands (305808)

The following `diag npc np6` commands have been reintroduced into 5.6.0.

These options were available in 5.2.x but were not in 5.4.0

- `diag npc np6 gmac-stats` - Shows the GMAC MIBs counters
- `diag npc np6 gmac-stats-clear` - Clears the GMAC MIBS counters
- `diag npc np6 gige-port-stats` - Shows the GIGE PORT MIBs counters
- `diag npc np6 gige-port-stats-clear` - Clears the GIGE PORT MIBs counters

### Diagnose command to show firewall service cache (355819)

A diagnostic command has been added to dump out the service name cache kept by the `miglogd` daemon for each individual VDOM.

```
diag test app miglogd 106
```

### Example output:

This output has been edited down to conserve space. Only the first 5 of each grouping has been included.

```

diag test app miglogd 106
tcp
port(0), name(NONE)
port(21), name(FTP)
port(22), name(SSH)
port(23), name(TELNET)
port(25), name(SMTP)
udp
port(53), name(DNS)
port(67--68), name(DHCP)
port(69), name(TFTP)
port(88), name(KERBEROS)

```

```

port(111), name(ONC-RPC) extra: (ONC-RPC) (NFS)
icmp
port(1), name(test)
port(8), name(PING)
port(13), name(TIMESTAMP)

general
prot(6), port(4300), name(example.com_Webadmin)
prot(6), port(5060), name(SIP)
prot(6), port(5190--5194), name(AOL)
prot(6), port(5631), name(PC-Anywhere)
prot(6), port(5900), name(VNC)
service names:
WINFRAME, DNS, DCE-RPC, H323, RLOGIN, IRC, UUCP, example.com_Webadmin, HTTPS, WAIS, FINGER, REXEC,
RAUDIO, SNMP, TIMESTAMP, RADIUS-OLD, DHCP, AOL, MGCP, SMTPS, INFO_REQUEST, HTTP, SCCP, SOCKS, PPTP,
ONC-RPC, NNTP, SMTP, QUAKE, PC-Anywhere, TFTP, NONE, SSH, RSH, IMAPS, LDAP_UDP, SIP, RIP, PING, PING6,
X-WINDOWS, SMB, SAMBA, TRACEROUTE, NFS, WINS, L2TP, IMAP, GOPHER, SIP-MSNmessenger, SYSLOG, DHCP6,
TELNET, LDAP, MS-SQL, MMS, KERBEROS, SQUID, NTP, FTP, CVSPSERVER, test, AFS3, POP3, Internet-Locator-
Service,
service groups:
Email Access (DNS, IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS,)
Windows AD (DCE-RPC, DNS, KERBEROS, LDAP, LDAP_UDP, SAMBA, SMB,)
Web Access (DNS, HTTP, HTTPS,)
Exchange Server (DCE-RPC, DNS, HTTPS,)
policies involving multiple service definitions:

```

## Diagnose command to show crash history and adjust crash interval (366691)

In order to alleviate the impact logging put on resources if processes repeatedly crash, limits have been put on crash logs.

- The default limit is 10 times per 60 minutes for crash logs. This limit can be edited using the command:

```
diagnose debug crashlog interval <interval>
```

<interval> is the number of second to log crash logs for a particular process

- The `miglogd` daemon is the only one to write crash logs directly. Crash logs from other processes are done through `miglogd`.
- Crash logs for a single crash are written all at once so that the logs are easier to read if there are crashes of multiple processes at the same time.
- A `diagnose` command has been added to show crash history.

```

# diagnose debug crashlog history
# Crash log interval is 3600 seconds
# reportd crashed 2 times. The latest crash was at 2016-12-01 17:53:45

```

## diagnose switch-controller commands (368197)

The following `diagnose` commands in the CLI, are designed to

- Output stats on the managed switches
- Kick the client from the managed switches

```
diagnose switch-controller dump lldp neighbors-summary <device-id> <portid>
```

```
diagnose switch-controller dump lldp neighbors-detail <device-id> <portid>
```

```
diagnose switch-controller dump lldp Stats <device-id>
diagnose switch-controller dump port-stats <device-id>
diagnose switch-controller dump trunk-state <device-id>
diagnose switch-controller kick <device-id> <vlan ID> <port ID> <MAC ID>
```

While not a diagnostic command, the following can also be run from VDOMs

```
execute replace-device fortiswitch <device-id>
```

These commands are now longer restricted to being run from the root VLAN and can be run from any VDOM

### Diagnose commands for monitoring NAT sessions (376546)

We have developed the following monitoring capabilities in CLI and SNMP.

- NAT sessions per IP pool
- Total tcp sessions per IP pool
- Total udp sessions per IP pool
- Total others (non-tcp and non-udp) sessions per IP pool

FortiGate supports 4 types of NAT, which are

- Overload
- One-to-one
- Fixed-port-range
- Port-block-allocation.

#### diagnose firewall ippool-all

- list - lists all of the IP Pools
- stats - Statistics of the IP Pools

##### list

```
diagnose firewall ippool-all list
```

##### Example output:

```
vdom:root owns 4 ippool(s)
name:Client-IPPool
type:port-block-allocation
nat-ip-range:10.23.75.5-10.23.75.200
name:Fixed Port Range
type:fixed-port-range
nat-ip-range:20.20.20.5-20.20.20.50
name:One to One
type:one-to-one
nat-ip-range:10.10.10.5-10.10.10.50
name:Sales_Team
type:overload
nat-ip-range:10.23.56.18-10.23.56.20
```

## Stats

This option has two methods of being used. By just hitting enter after stats, the output contains the stats for all of the IP Pools. By putting the name of an IP Pool after stats, the output is filtered so that only stats relating to that particular IP Pool is included in the output.

### Example output #1

```
# diagnose firewall ippool-all stats
vdom:root owns 5 ippool(s)
name: Client-IPPool
type: port-block-allocation
startip: 10.23.75.5
endip: 10.23.75.200
total ses: 0
tcp ses: 0
udp ses: 0
other ses: 0
name: Fixed Port Range
type: fixed-port-range
startip: 20.20.20.5
endip: 20.20.20.50
total ses: 0
tcp ses: 0
udp ses: 0
other ses: 0
name: One to One
type: one-to-one
startip: 10.10.10.5
endip: 10.10.10.50
total ses: 0
tcp ses: 0
udp ses: 0
other ses: 0
name: Sales_Team
type: overload
startip: 10.23.56.18
endip: 10.23.56.20
total ses: 0
tcp ses: 0
udp ses: 0
other ses: 0
```

### Example #2

```
# diagnose firewall ippool-all stats "Sales_Team"
name: Sales_Team
type: overload
startip: 10.23.56.18
endip: 10.23.56.20
total ses: 0
tcp ses: 0
udp ses: 0
other ses: 0
```

## SIP diagnose command improvements (376853)

A diagnose command has been added to the CLI that outputs VDOM data located in the voipd daemon.

```
diagnose sys sip-proxy vdom
```

### Example

```
(global) # diagnose sys sip-proxy vdom
VDOM list by id:
vdom 0 root (Kernel: root)
vdom 1 dmngmt-vdom (Kernel: dmngmt-vdom)
vdom 2 test2 (Kernel: test2)
vdom 3 test3 (Kernel: test3)
vdom 4 vdoma2 (Kernel: vdoma2)
vdom 5 vdomb2 (Kernel: vdomb2)
vdom 6 vdomc2 (Kernel: vdomc2)
vdom 7 vdoma (Kernel: vdoma)
vdom 8 vdomb (Kernel: vdomb)
vdom 9 vdomc (Kernel: vdomc)
VDM list by name:
vdom 1 dmngmt-vdom (Kernel: dmngmt-vdom)
vdom 0 root (Kernel: root)
vdom 2 test2 (Kernel: test2)
vdom 3 test3 (Kernel: test3)
vdom 7 vdoma (Kernel: vdoma)
vdom 4 vdoma2 (Kernel: vdoma2)
vdom 8 vdomb (Kernel: vdomb)
vdom 5 vdomb2 (Kernel: vdomb2)
vdom 9 vdomc (Kernel: vdomc)
vdom 6 vdomc2 (Kernel: vdomc2)
```

## Diagnose command to get AV virus statistics (378870)

A new diagnostic command has been added for the showing of AV statistics. This can be used within each VDOM

### Syntax:

```
diagnose ips av stats show
```

### Example output

```
diagnose ips av stats show
AV stats:
HTTP virus detected: 0
HTTP virus blocked: 0
SMTP virus detected: 0
SMTP virus blocked: 0
POP3 virus detected: 0
POP3 virus blocked: 0
IMAP virus detected: 0
IMAP virus blocked: 0
NNTP virus detected: 0
NNTP virus blocked: 0
FTP virus detected: 0
FTP virus blocked: 0
```

```
SMB virus detected: 0
SMB virus blocked: 0
```

### Diagnose command to get remote FortiSwitch trunk information (379329)

To ensure that a FortiGate and its managed FortiSwitches stay in synchronization in the event of an inadvertent trunk table change situation, there is a new CLI setting that checks for discrepancies.

The idea is to check to see if there will be a synchronization issue between the FortiGate and the FortiSwitch before applying the configuration

1. On fortilink reconnection, FGT reads trunk table of FSW using REST API GET-- Hence FGT gets all the port and its trunk membership information from FSW
2. FGT then compares its managed FSW trunk information with received FSW information
3. If there is any conflict, FGT will delete extra/conflicted trunk on FSW using REST API POST
4. At the end FGT replays all configuration to FSW as usual

This will help delete the extra trunks, conflicted trunks on the FSW and to make sure in sync

Possible reasons for losing synchronization include:

- The FortiGate reboots after a factory reset while there is still a trunk configuration in the FortiSwitch.
- The managed FortiSwitch's trunk table gets edited on the FortiGate while the FortiSwitch is offline.
- A trunk table on the FortiSwitch gets added or the existing one gets modified or deleted by a user.

New diagnose command for the CLI:

```
diagnose switch-controller dump trunk-switch-config <Managed FortiSwitch device ID>
```

### help provided for diagnose debug application csfd (379675)

The syntax for the command is:

```
diagnose debug application csfd <Integer>
```

The <Integer> being the debug level. To get the integer value for the debug level, run the command without the integer. You will get the following:

```
# diagnose debug application csfd
csfd debug level is 0 (0x0)
Error 0x01
Warning 0x02
Function trace 0x04
Information 0x08
Detail 0x10
MAC packet encryption debug 0x20
MAC learning debug 0x40
FAZ configuration synchronize debugging 0x0080
FAZ configuration function trace 0x00100
Configuration tree update debug 0x00200
Configuration tree function trace 0x00400
HA Sync plugin debug 0x00800
```

Convert the value next to the debug level you want to an integer. For example, to set the debug level to Information, convert 0x08 to 8 and use it for the option at the end of the command.

```
# diagnose debug application csfd 8
```

## New IPS engine diagnose commands (381371)

Periodically, when troubleshooting, an different IPS engine will need to be installed on the FortiGate but there will also be a restriction that the FortiGate can't be rebooted. Normally, a new IPS engine will not be fully recognized by the system until after a reboot. This command allows the running of new commands or new versions of commands in the IPS engine without having to reboot the FortiGate.

```
diagnose ips test cmd <command strings>
```

The command strings are separated by a semicolon such as:

```
diagnose ips test cmd command1;command2;command3
```

### Examples:

- `diagnose ips test cmd "ips session status"`

This command triggers the diagnosis command in the double quotation marks: "diagnose ips session status"

- `diag ips test cmd "ips memory track; ips memory status; ips session status"`

This command triggers the diagnosis commands in the double quotation marks in order.

The results:

```
Commands[0]: ips memory track
----< execute "diagnose ips memory track" >----
Commands[1]: ips memory status
----< execute "diagnose ips memory status" >----
Commands[2]: ips session status
----< execute "diagnose ips session status" >----
```

## New AV engine diagnose commands (383352)

The purpose of this diagnostic command is to display information from within the AV engine for the purposes of aiding trouble shooting and diagnostics if the AV engine crashes or times out.

The command is:

```
diagnose antivirus test
```

It's syntax can be one of the following:

```
diagnose antivirus test <command>
diagnose antivirus test <command argument1>; <argument2>; ...
```

The command is defined and interpreted by the AV engine. FortiOS just passes the CLI command into the AV engine and outputs the strings returned by AV engine.

In AV engine 5.4.239, the following command are supported.

- `get scantypes`
- `set scantypes`
- `debug`

### NPU diagnose command now included HPE info in results (384692)

There is no change to the CLI but the results of the `diagnose npu np6 npu-feature` command now include results regarding HPE.

### clear checksum log files (diag sys ha checksum log clear) (385905)

There is currently a command, `diag sys ha checksum log [enable | disable]` that enables a checksum debug log by saving checksum calculations to a temp file. However, the checksum calculations saved in this file can be processed by two different functions, `cmdbsvr` and the CLI.

The function `cmf_context-is-server()` now enables the determining whether the running process is `cmdbsvr` or the CLI and also a diagnose command has been added to clear the contents of the file.

```
diag sys ha checksum log clear
```

### new diagnose command to delete avatars (388634)

It is now possible to delete avatars associated with FortiClient clients.

```
diagnose endpoint avatar delete <FortiClient UID>
```

or

```
diagnose endpoint avatar delete <FortiClient UID> <username>
```

- If only the FortiClient UID is used, all of the avatars, except those that are currently being used will be deleted.
- If both the FortiClient UID and the username are used, all of the avatars that belong to that combination, except those being used, will be deleted.

### CID signatures have been improved for DHCP and CDP (389350, 409436)

More parameters have been added to make them more specific. This helps to reduce false positives.

- DHCP signatures:
  - A new dhcp signature file has been added 'cid.dhcp2' that allows for the class and host name to be specified in the same signature. This is for increased accuracy.
  - Relevant signatures from 'cid.dhcp' have been ported to the new signature file 'cid.dhcp2'
  - Support DHCP parameter matching in signatures.
  - Support DHCP option list matching in signatures.
- CDP mac analyzer now passes all three keys to the OS matcher.
- Tests:
  - A number of new tests (including pcaps) have been added to match existing signatures and new signatures.
  - Some tests where multiple protocols were present in a single pcap, have been modified. These are now split into multiple pcaps, each containing a single protocol. This allows FortiOS to fully test a signature, where previously a single test may have matched multiple signatures.
- CID debug statistics now use shared memory. This prevents the daemon from having to respond to CLI requests and allows for the stats to persist across daemon restarts.
  - A Change has been made to the host ip update priority. IP changes for routers that have had their type set by heuristic are not allowed to change IPs.

- If it is a Fortinet device, the change is allowed if it comes through a protocol we trust more (CDP, DHCP, LLDP, or MAC).

### diagnose command to calculate socket memory usage (392655)

This diagnostic command gives the socket memory usage by individual process.

```
diagnose sys process sock-mem <pid>; <pid> ...
```

Separate arguments with a semicolon ";"

#### Example

Run diagnose sys top to get the pid of a few process...

```
diagnose sys top
Run Time: 1 days, 0 hours and 44 minutes
0U, 0N, 0S, 100I, 0WA, 0HI, 0SI, 0ST; 7996T, 5839F
httpd 214 S 0.1 0.2
httpd 1398 S 0.1 0.2
snmpd 173 S 0.1 0.1
```

Then use those pid with the command...

```
diagnose sys process sock-mem 214; 173
Process ID=214, sock_mem=0 (bytes)
Process ID=173, sock_mem=2 (bytes)
```

### FortiGuard can determine a FortiGate's location from its public IP address (393972)

The FortiGate now shows the public IP address and the geographical location (country) in the dashboard. The FortiGate sends a ping to the FortiCare/FortiGuard network and as a response receives the local WAN IP, or if it is being NATed the public IP of the network. Using the public IP address a geo-ip Blackpool is done to determine the country.

In the same location on the Dashboard, it also shows whether or not the listed IP address is a member of the Fortinet Blacklist.

## CLI

The diagnostic command to get the information is:

```
diag sys waninfo
```

#### Example:

```
diagnose sys waninfo
Public/WAN IP: 209.87.240.98
Location:
Latitude: 45.250100
Longitude: -75.916100
Accuracy radius: 5
Time zone: America/Toronto
City: Stittsville
Subdivisions:
0: Ontario
```

```

Country: Canada
Postal:
Code: K2S
Continent: North America
Registered country: Canada
ISP: Unknown

Failed to query whether 209.87.240.98 is in the FortiGuard IP Blacklist: ret=-1 buf_
sz=1024
Command fail. Return code 5

```

To get information about the address's inclusion as a member of the Fortinet Blacklist, the command is:

```
diag fortiguard ipblacklist [db | vr | ip | ctx]
```

- db - Get Database and Vendor/Reason List Versions.
- vr - Get Vendor/Reason List.
- ip - Get Information on Specific IP.
- ctx - Show Local Context.

If using the ip option, specify the IPv4 address after the ip option.

Example:

```
diagnose fortiguard ipblacklist ip 209.87.240.98
```

## AWS bootstrapping diagnose commands (394158)

Bootstrap feature is quite similar to cloudinit in Openstack. When user launching a new instance of FGT-VM in AWS, it needs to provide some basic information of license and config stored in AWS s3 bucket via userdata. Bootstrap will download license and config from s3 bucket and apply them to FGT automatically.

## CLI

Add a new cli to show the results of bootstrap config apply.

**Example:**

```

diagnose debug aws-bootstrap show
>> FGVM040000066475 $ config sys glo
>> FGVM040000066475 (global) $ set hostname awsondemand
>> FGVM040000066475 (global) $ end

```

## Diagnose command to aid in conserve mode issues (394856)

The `diagnose hardware sys conserve` command provides memory information about the system that is useful in diagnosing conserve mode issues.

**Example**

```

diagnose hardware sys conserve
memory conserve mode: off
total RAM: 7996 MB
memory used: 2040 MB 25% of total RAM
memory used threshold extreme: 7597 MB 95% of total RAM
memory used threshold red: 7037 MB 88% of total RAM
memory used threshold green: 6557 MB 82% of total RAM

```

## Diagnose commands to display FortiCare registration information (395254)

The Dashboard License widget can display information about the registered company owner and industry. There are some diagnostic commands that can do that in the CLI.

```
diagnose forticare protocol [HTTP | HTTPS]
diagnose forticare server < server IP>
diagnose forticare cnreg-code-list - List of known ISO 3166-1 numeric country/region
codes.
diagnose forticare direct-registration reseller-list <cnreg-code>
diagnose forticare direct-registration country-data <cnreg-code>
diagnose forticare direct-registration organization-list
diagnose forticare direct-registration product-registration <arguments>
```

### Options/arguments for product registration:

- a = account\_id
- A = address
- y = city
- C = company
- c = contract\_number
- T = country\_code
- e = existing\_account
- F = fax
- f = first\_name
- h = help
- I = industry
- i = industry\_id
- l = last\_name
- O = orgsize
- o = orgsize\_id
- p = password
- P = phone
- z = postal\_code
- R = reseller
- r = reseller\_id
- S = state
- s = state\_code
- t = title
- v = version

## new diag test app csfd options (395302)

Two additional test levels have been added to the `diag test app csfd` command in order to dump some additional information about timers, file handlers status and received MAC addresses to the HA master.

```
diag test app csfd 11
diag test app csfd 40
```

### **new 'AND' and 'OR' filter capabilities for debug flow addr (398985)**

In order to make a more flexible filter for the debug flow address command, the Boolean arguments of 'AND' and 'OR' have been added to the command parser. This will work regardless of whether or not the source or destination address is being filtered.

Syntax:

```
diagnose debug flow filter address <IP1|from IP> <IP2|to IP> <ENTER|and/or>
```

### **Improve wad debug trace and crash log information (400454)**

Previously, when filtering on a wad debug trace or crash log information, the information may not have been as targeted as necessary. A new setting has been added to target a specific policy.

```
diagnose wad filter firewall-policy <index>
diagnose wad filter explicit-policy <index>
```

These commands will target the firewall or explicit proxy policies. Using a "-1" as the value will index of that particular policy type.

### **diagnose hardware test added to additional models (403571)**

The diagnose hardware test that was previously on FortiGate E Series models, and the FortiGate 300/500D models, has been expanded to include:

- Multiple low range models
- Multiple mid range models
- FortiGate 3800D model

This diagnostic feature replaces much of the functionality of the HQIP test that requires the installation of a separate firmware image.

### **diag sys sip-proxy config profile --> diag sys sip-proxy config profiles (404874)**

Diagnose command has been changed to make it more consistent with other similar commands.

```
diagnose sys sip-proxy config profile
```

has been changed to

```
diagnose sys sip-proxy config profiles
```

### **diag debug flow changes (405348)**

For crash and console logs, the logs are no longer parsed before being sent to their destination. Now they are dumped directly to the destination.

In addition the following options have been removed from the diagnose command list:

```
diag debug flow show console
diag debug flow show console enable
diag debug flow show console disable
```

## improve wad memory diagnose process (408236)

The WAD SSL memory dump functions have been moved to migbase so they can be shared by both WAD and CLI.

### CLI additions

- `diagnose wad memory` - WAD memory diagnostics
- `diagnose wad memory general` - List of WAD memory blocks.
- `diagnose wad memory bucket` List suspicious WAD memory buckets.
- `diagnose wad memory ssl` List SSL memory statistics

## New daemon watchdog framework in forticron (409243)

A new feature has been added to dump userspace's process stacks.

### CLI additions:

```
diagnose sys process pstack <pid>
```

<pid> - Process ID, such as those displayed when using `diagnose sys top`

## Output from diagnose wad debug command filterable(410069)

The output from the command was so verbose that there was some concern that the information that was being looked for could get lost in all of the extraneous data so some parameters were added that allow the information to be filtered by both severity level and the category of the information.

The command has a few settings

```
diagnose wad debug [enable|disable|show|clear|display]
```

- `enable` - Enable the level or category debug setting.
- `disable` - Disable debug setting.
- `show` - Show the current debug setting.
- `clear` - Clear the exiting debug setting.
- `display` - Changes to the Display setting.
  - `diag wad debug display pid enable` - enables the display of PID values in the output.

### Syntax to set the level

```
diagnose wad debug enable level <level>
```

Where the <level> is one of:

- `error` - error
- `warn` - warning
- `info` - information
- `verbose` - verbose

### Syntax to set the category

```
diag wad debug enable category <category>
```

Where <category> is one of the following:

- `connection` - connection
- `session` - session
- `protocol` - protocol
- `io` - I/O
- `packet` - packet
- `db` - cache database
- `cifs` - CIFS
- `ssl` - SSL
- `webcache` - webcache
- `policy` - policy matching
- `auth` - authentication
- `scan` - UTM scan
- `cache` - wanopt cache
- `tunnel` - wanopt tunnel
- `bank` - bank
- `stats` - stats
- `disk` - cache disk
- `video` - cache video
- `rplmsg` - replacement message
- `ipc` - IPC
- `bar` - Fortinet top bar
- `waf` - WAF
- `memblk` - memory block
- `all` - all category

### DNS log improvements (410132)

DNS logs have been improved to make the presentation of the data clearer. These changes involve a reorganization of the DNS log subtypes.

These changes include:

- Change `dns-subtype` to `dns-response`
- Remove `status` field and add Pass/Block/Redirect to `action` field
- Change the `msg` field display DNS filter rating results
- All error messages now to the `error` field
- Change `urlfilteridx` to `domainfilteridx`
- Change `urlfilterlist` to `domainfilterlist`
- Add a query type value field.

## Explicit web proxy (5.6)

New explicit web proxy features added to FortiOS 5.6.

### Explicit proxy supports multiple incoming ports and port ranges (402775, 398687)

Explicit proxy can now be configured to listen on multiple ports on the same IP as well as listen for HTTP and HTTPS on those same (or different) ports.

Define the IP ranges using a hyphen (-). As shown below, `port_high` is not necessary to specify if `port_low` is equal to `port_high`.

#### CLI syntax

```
config web-proxy explicit
  set http-incoming-port <port_low> [-<port_high>]
end
```

### Explicit proxy supports IP pools (402221)

Added a new command, `poolname`, to `config firewall proxy-policy`. When setting the IP pool name with this command, the outgoing IP will be selected.

#### CLI syntax

```
config firewall proxy-policy
  edit <example>
    set poolname <name>
  end
```

### Option to remove unsupported encoding from HTTP headers (392908)

Added a new command to `config web-proxy profile` that, when enabled, allows the FortiGate to strip out unsupported encoding from request headers, and correctly block banned words. This is to resolve issues when attempting to successfully block content using Google Chrome.

#### CLI syntax:

```
config web-proxy profile
  edit <example>
    set strip-encoding {enable | disable}
  end
```

### New authentication process for explicit web proxying (386474, 404355)

While in Proxy inspection mode, explicit proxy options can be set under **Network > Explicit Proxy**. These settings will affect what options are available for creating proxy policies under **Policy & Objects > Proxy Policy**. From here you may create new policies with **Proxy Type** set to either **Explicit Web**, **Transparent Web**, or **FTP**.

Authentication will be triggered differently when configuring a transparent HTTP policy. Before such a policy can be configured, you must enable **HTTP Policy Redirect** under **Security Profiles > Proxy Options**.

### Added Internet services to explicit proxy policies (386182)

Added two new commands to `config firewall proxy-policy`. FortiOS can use the Internet Service Database (introduced in 5.4.1) as the web-proxy policy matching factor.

#### CLI syntax:

```
config firewall proxy-policy
edit <example>
set internet-service <application-id>
set internet-service-custom <application-name>
```

### Virtual WAN link in an explicit proxy firewall policy (385849, 396780)

Virtual WAN link (VWL) interfaces may now be set as the destination interface in an explicit proxy policy, routing traffic properly using basic virtual WAN link load balance settings. This is now configurable through both the CLI under `firewall proxy-policy` and the GUI.

### Added application ID and category setting on the explicit proxy enabled service (379330)

This feature introduces support for application ID/category in the service of explicit proxy as one policy selection factor. The intent is to identify the application type based on the HTTP request with IPS application type detection function. It is similar to the current firewall explicit address, but it is implemented as a service type, and you can select the application ID/ category to define explicit service. Of course, now it must be an HTTP-based application.

#### CLI syntax

```
config firewall service custom
edit "name"
set app-service-type [disable|app-id|app-category]
next
end
```

### Explicit Proxy - populate pac-file-url in transparent mode (373977)

You can now use `manageip` to populate `pac-file-url` in transparent opmode. Previously, in the CLI, when displaying `pac-file-url`, the code only tries to get interface IP to populate `pac-file-url`.

#### CLI syntax

```
config vdom
edit root
config system settings
set opmode transparent
set manageip 192.168.0.34/24
end
config web-proxy explicit
set pac-file-server-status enable
get pac-file-url [url.pac]
end
```

### SSL deep inspection OCSP support for Explicit Proxy (365843)

OCSP support for SSL deep inspection added for Explicit Proxy.

**CLI syntax**

```
config vpn certificate setting
  set ssl-ocsp-status [enable|disable]
  set ssl-ocsp-option [certificate|server]
end
```

**Timed out authentication requests are now logged (357098)****CLI syntax**

```
config web-proxy explicit
  set trace-auth-no-rsp [enable|disable]
end
```

## Firewall (5.6.3)

New firewall features added to FortiOS 5.6.3.

### Multi-port support for Explicit Proxy (402775)

Support has been added for the use of multiple ports and port range in the explicit FTP or Web proxies. These changes have been added in both CLI and GUI.

CLI changes:

```
set http-incoming-port <port_low>[-<port_high>]
```

Where:

- `port_low` - the low value of the port
- `port_high` - the high value of the port

The `port_high` value can be omitted if `port_low` and `port_high` are the same.

### Nturbo support CAPWAP traffic and fix IPsec IPv6 firewall policy code typo (290708) (423323)

NTurbo is used for IPSEC+IPS case. The IPSEC SA info is passed to NTURBO as part of VTAG for control packet and will be used for the xmit.

If the packets need to go through IPSEC interface, the traffic will be always offloaded to Nturbo. But for the case that SA has not been installed to NP6 because of hardware limitation or SA offload disable, the packets will be sent out through raw socket by IPS instead of Nturbo, since the software encryption is needed in this case.

CLI Changes:

Previously, NTurbo could only be enabled or disabled globally. The setting of `np-acceleration` has been added to the firewall policy context instead of just the global context.

Add: Added a CLI command in the firewall policy to enable/disable NTurbo acceleration.

```
config firewall policy
edit 1
set np-acceleration [enable|disable]
end
```

When IPS is enabled for VPN IPsec traffic, the data can be accelerated by NTurbo now.

### Toggling SNAT in Central SNAT policies (434981)

The central NAT feature is not enabled by default. When `central-nat` is enabled, `nat` option under IPv4 policies is skipped and SNAT must be done via `central-snat-map`.

- Info messages and redirection links have been added to IPv4 policy list and dialog to indicate the above
- If NGFW mode is policy-based, then it is assumed that `central-nat` (specifically SNAT) is enabled implicitly
- The option to toggle NAT in `central-snat-map` policies has been added (previously it was only shown in NGFW policy-based mode).

- In central-snat policy dialog, the port-mapping fields for the original port have been updated to accept ranges.
- Nat will be skipped in firewall policy if per vdom central nat is enabled.

### Example scenarios to show changes in how CLI treats central-nat

#### Change: make nat available regardless of NGFW mode.

```
config firewall central-snat-map
edit 1
set orig-addr "192-86-1-86"
set srcintf "port23"
set dst-addr "192-96-1-96"
set dstintf "port22"
set nat-ippool "pool1"
set protocol 17
set orig-port 2896-2897
set nat enable
end
```

#### Change: hide nat-port if nat-ippool is not set or NAT is disabled.

```
config firewall central-snat-map
edit 1
set orig-addr "192-86-1-86"
set srcintf "port23"
set dst-addr "192-96-1-96"
set dstintf "port22"
set nat-ippool "pool1"
set protocol 17
set orig-port 2896-2897
set nat disable
end
```

#### Change:change orig-port to accept range

```
config firewall central-snat-map
edit 1
set orig-addr "192-86-1-86"
set srcintf "port23"
set dst-addr "192-96-1-96"
set dstintf "port22"
set nat-ippool "pool1"
set protocol 17
set orig-port 2896-2897 (help text changed to: Original port or port range).
set nat-port 35804-35805
end
```

### Improved wildcard support for firewall fqdn (444646)

The following wildcard character instances are now supported in wildcard FQDN addresses:

- "?" character
- "\*" character in the middle of a phrase
- The "?\*" combination

## Policy Matching based on Referrer Headers and Query Strings (446257)

Web proxy policies support creating web proxy addresses to match referrer headers and query strings.

### Matching referrer headers

For example, to create a web proxy address to match the referrer header to block access to the following YouTube URL <http://youtube.com/user/test321>. The http request will have the following format:

```
GET /user/test321 HTTP/1.1
Host: www.youtube.com
User-Agent: curl/7.52.1
Accept: */*
```

Create the following web proxy addresses to match this page:

```
config firewall proxy-address
edit youtube
set type host-regex
set host-regex ".*youtube.com"
next
edit test321
set host "youtube"
set path "/user/test321"
set referrer enable
end
```

Then create two proxy policies, one that allows access to all traffic and a second one that blocks access to the page that matches the referrer header:

```
config firewall proxy-policy
edit 1
set uuid 92273e4e-8c53-51e7-a7bd-f26e6e15fc98
set proxy explicit-web
set dstintf "wan2"
set srcaddr "all"
set dstaddr "all"
set service "webproxy-connect"
set action accept
set schedule "always"
set utm-status enable
set profile-protocol-options "test"
set ssl-ssh-profile "test"
next
edit 2
set uuid d35ad06a-8c53-51e7-8511-17200f682a4a
set proxy explicit-web
set dstintf "wan2"
set srcaddr "all"
set dstaddr "test321"
set service "webproxy"
set action accept
set schedule "always"
set utm-status enable
set av-profile "default"
set profile-protocol-options "test"
set ssl-ssh-profile "test"
end
```

## Matching query strings

To match the video with URL `youtube.com/watch?v=XXXXXXXXXX`, (where `XXXXXXXXXX` is an example YouTube query string) you need to match an HTTP request with the following format:

```
GET /user/watch?v=GLCHldlwQsg HTTP/1.1
Host: www.youtube.com
User-Agent: curl/7.52.1
Accept: */*
```

Create the following web proxy addresses to match this video or query string:

```
config firewall proxy-address
edit "youtube"
set uuid 4ad63880-971e-51e7-7b2e-c69423ac6314
set type host-regex
set host-regex ".*youtube.com"
next
edit "query-string"
set uuid 7687a8c0-9727-51e7-5063-05edda03abbf
set host "youtube"
set path "/watch"
set query "v=XXXXXXXXXX"
end
```

Then create two proxy policies, one that allows access to all traffic and a second one that blocks access to the page that matches the query string

```
config firewall proxy-policy
edit 1
set uuid 92273e4e-8c53-51e7-a7bd-f26e6e15fc98
set proxy explicit-web
set dstintf "wan2"
set srcaddr "all"
set dstaddr "all"
set service "webproxy-connect"
set action accept
set schedule "always"
set utm-status enable
set profile-protocol-options "test"
set ssl-ssh-profile "test"
next
edit 2
set uuid d35ad06a-8c53-51e7-8511-17200f682a4a
set proxy explicit-web
set dstintf "wan2"
set srcaddr "all"
set dstaddr "query-string"
set service "webproxy"
set action accept
set schedule "always"
set utm-status enable
set av-profile "default"
set profile-protocol-options "test"
set ssl-ssh-profile "test"
next
end
```

## Firewall (5.6.1)

New firewall features added to FortiOS 5.6.1.

### Improvement to NAT column in Policy List Display (305575)

The NAT column in the listing of Policy can provide more information than before.

Previously the field for the policy in the column only showed whether NAT was **Enabled** or **Disabled**.

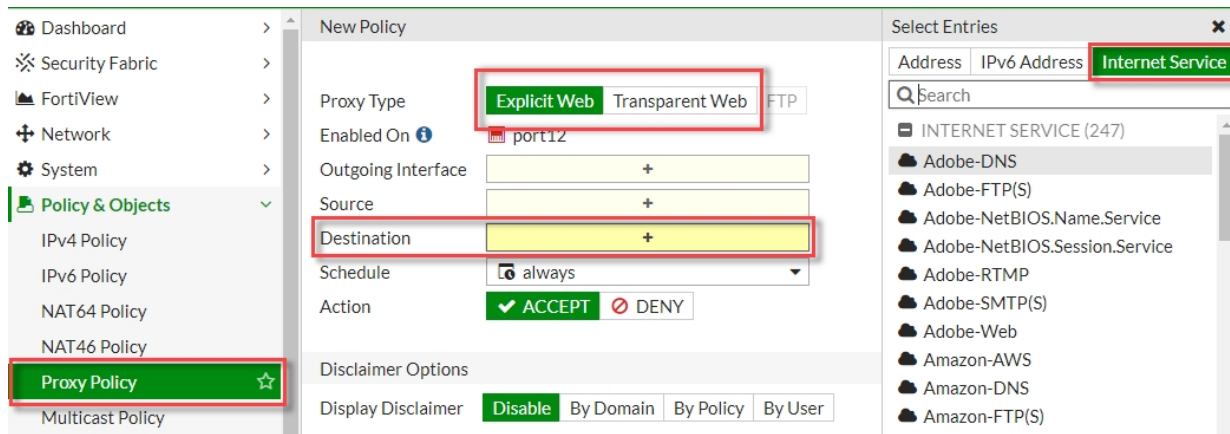

With the new improvements, not only does the field show the name of the Dynamic Pool, if one is being used, but the tool-tip feature is engaged if you hover the cursor over the icon in the field and provides even more specific information.

### GUI support for adding Internet-services to proxy-policies (405509)

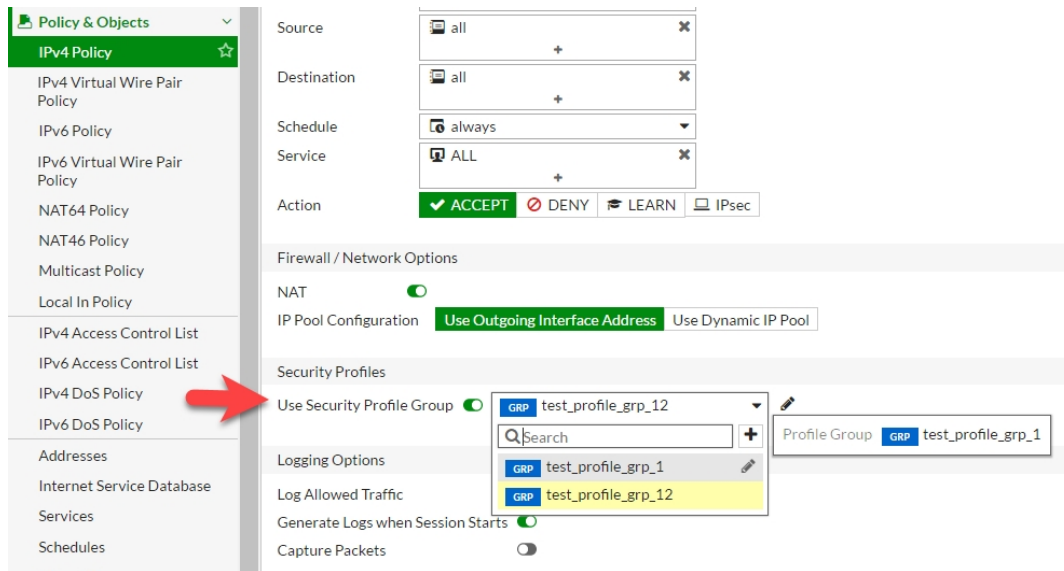

There is now GUI support for the configuration of adding Internet services to proxy policies. When choosing a destination address for a Proxy Policy, the Internet Service tab is visible and the listed objects can be selected.

By choosing an **Internet Service** object as the **Destination**, this sets `internet-service` to enable and specifying either an **Address** or **IPv6 Address** object will set `internet-service` to disable.

### Inline editing of profile groups on policy (409485)

There can now be editing to the profile groups within the policy list display window. Before, you had to go into the edit window of the policy, such as in the image below:

However, now the editing can be done from the list display of policies and clicking on the GRP icon. Right clicking on the icon will slide a window out from the left and left clicking will give you a drop-down menu.

### Rename "action" to "nat" in firewall.central-snat-map (412427)

The `action` field option in the context of `firewall central-snat-map` in the CLI was considered by some to be a little ambiguous, so it has been renamed to `nat`, an option that can either be `enabled` or `disabled`.

### Explicit proxy supports session-based Kerberos authentication (0437054)

- Explicit proxy supports session-based Kerberos authentication
- Transparent proxy will create an anonymous user if the an attempt to create a NTLM connection fails.
- When FSSO authentication fails for the explicit FTP proxy, the FortiGate responses with the error message "match policy failed".

## Firewall (5.6)

New firewall features added to FortiOS 5.6.

### Optimization of the firewall Service cache (355819)

In order to improve the efficiency and performance of the firewall Service cache, the following improvements have been made:

- The logic behind the structure of the cache has been simplified. Instead of storing ranges of port numbers, we store each individual port number in the cache
- Separate caches are created for each VDOM so that cache searches are faster.
- The performance of more frequently used cases has been increased
- Hash tables are used to improve the performance of complex cases. These could include such instances as:
  - service names tied to specific IP Ranges
  - redefinition (one port number with multiple service names)

### New CLI option to prevent packet order problems for sessions offloaded to NP4 or NP6 (365497)

In order to prevent the issue of a packet, on FortiGate processing a heavy load of traffic, from being processed out of order, a new setting has been added to better control the timing of pushing the packets being sent to NP units.

The new option, `delay-tcp-npc-session`, has been added into the context of config firewall policy within the CLI

```
config firewall policy
  edit <Integer for policy ID>
    set delay-tcp-npc-session
  end
```

Policy may not be available on units not using NP units.

### GUI changes to Central NAT (371516)

The Central NAT configuration interface prevents the accidental occurrence of being able to select "all" and "none" as two objects for the same field. It only allows the selecting of a single IP pool, though it is still possible to

select multiple IP pools within the CLI.

### Max value for Firewall User authentication changed (378085)

Previously, the maximum time that a member of a firewall user group could remain authenticated without any activity was 24 hours (1440 minutes). The maximum value for this setting has been changed to 72 hours (4320 minutes). This allow someone to log in but not be kicked off the system due to inactivity over the course of a weekend.

The syntax in the CLI for configuring this setting is:

```
config user group
  edit <name of user group>
    set authtimeout 4320
  end
```

### Changes to default SSL inspection configuration (380736)

SSL is such a big part of normal traffic that SSL certificate inspection is no longer disabled by default. SSL inspection is now mandatory in firewall policies whenever a policy includes a security profile. The default setting is the Certificate Inspection level. As a result there have been a few changes within the CLI and the GUI.

#### CLI

The setting SSL-SSH-Profile, is a required option, with the default value being "certificate-inspection", when it is applicable in the following tables:

- firewall.profile-group
- firewall.policy
- firewall.policy6,
- firewall.proxy-policy

The following default profiles are read-only:

- certificate-inspection
- deep-ssl-inspection

#### GUI

##### IPv4/IPv6 Policy and Explicit Proxy Policy edit window

- The configuration and display set up for SSL/SSH Inspection is now similar to "profile-protocol-option" option
- The disable/enable toggle button is no longer available for the Profile Protocol Option
- The default profile is set to "certificate-inspection"

##### IPv4/IPv6 Policy, Explicit Proxy Policy list page

- There is validation for SSL-SSH-Profile when configuring UTM profiles

##### SSL/SSH Inspection list page

- There is no delete menu on GUI for default ssl profiles
- The "Edit" menu has been changed to "View" for default SSL profiles
- The default SSL profile entries are considered an implicit class and are grayed out

##### SSL/SSH Inspection edit window

- The only input for default SSL profiles is now download/view trusted certificate links
- To return to the List page from default SSL profiles, the name of the button is now "Return"

#### Profile Group edit window

- There is no check box for SSL-SSH-Profile. It is always required.

#### Name change conventions due to upgrade

Starting in 5.6, the profiles "certificate-inspection" and "deep-inspection" are set up by the firmware as default read-only profiles. If you have profiles with these names that were configured in a previous version of FortiOS, rather than overwrite the firmware's default profile, profiles with these names will be upgraded to reflect the configuration conventions of the new firmware but the profile names will be changed by adding a prefix of "\_upg\_".

#### Add firewall policy comment field content to log messages (387865)

There has been a need by some customer to have some information in the logs that includes specific information about the traffic that produced the log. The rather elegant solution is that when the log-policy-comment option is enabled, the comment field from the policy will be included in the log. In order to make the logs more useful regarding the traffic just include a customized comment in the policy and enable this setting.

#### Syntax

```
config system settings
    set log-policy-comment [enable | disable]
end
```

- This setting is for all traffic and security logs.
- It can be select on a per VDOM basis

#### Learning mode changes profile type to single (387999)

The Learning mode does not function properly when it is applied to a policy that has a UTM profile group applied to it. The logging that should be taking place from the Learning Mode profiles does not occur as intended, and the

Automatically switching the profile type to single on a policy with Learning mode enabled prevents it from being affected by the UTM policy groups.

#### MAC address authentication in firewall policies and captive portals (391739)

When enabled, a MAC authentication request will be sent to `fnbamd` on any traffic. If the authentication receives a positive response, login becomes available. If the response is negative the normal authentication process takes over.

#### CLI

##### New option in the firewall policy setting

```
config firewall policy
    edit <policy ID>
        set radius-mac-auth-bypass [enable |disable]
    end
```

##### New option in the interface setting

```
config system interface
edit <interface>
set security-mode captive-portal
set security-mac-auth-bypass
end
```

### Display resolved IP addresses for FQDN in policy list (393927)

If a FQDN address object is used in a policy, hovering the cursor over the icon for that object will show a tool tip that lists the parameters of the address object. This tool tip now includes the IP address that the FQDN resolves to.

### Added comment for acl-policy, interface-policy and DoS-policy (396569)

A comment field has been added to the following policy types:

- acl-policy
- interface-policy
- DoS-policy

Comments of up to 1023 characters can be added through the CLI.

#### Examples:

##### DoS policy

```
config firewall DoS-policy
edit 1
set comment "you can put a comment here(Max 1023)."
```

##### Interface policy

```
config firewall interface-policy
edit 1
set comment "you can put a comment here(max 1023)."
```

##### Firewall ACL

```
config firewall acl
edit 1
set status disable
set comment "you can put a comment here(max 1023)."
```

```
set interface "port5"
set srcaddr "all"
set dstaddr "all"
set service "ALL"
end
```

## Internet service settings moved to more logical place in CLI (397029)

The following settings have moved from the application context of the CLI to the firewall context:

- `internet-service`
- `internet-service-custom`

### Example of `internet-service`

```
config firewall internet-service 1245324
set name "Fortinet-FortiGuard"
set reputation 5
set icon-id 140
set offset 1602565
config entry
edit 1
set protocol 6
set port 443
set ip-range-number 27
set ip-number 80
next
edit 2
set protocol 6
set port 8890
set ip-range-number 27
set ip-number 80
next
edit 3
set protocol 17
set port 53
set ip-range-number 18
set ip-number 31
next
edit 4
set protocol 17
set port 8888
set ip-range-number 18
set ip-number 31
next
end
```

### Example of `internet-service-custom`

```
config firewall internet-service-custom
edit "custom1"
set comment "custom1"
config entry
edit 1
set protocol 6
config port-range
edit 1
set start-port 30
```

```

        set end-port 33
      next
    end
    set dst "google-drive" "icloud"
  next
end
next
end

```

**Example of get command:**

```

get firewall internet-service-summary
Version: 00004.00002
Timestamp: 201611291203
Number of Entries: 1349

```

**Certificate key size selection (397883)**

FortiOS will now support different SSL certificate key lengths from the HTTPS server. FortiOS will select a key size from the two options of 1024 and 2048, to match the key size (as close as possible, rounding up) on the HTTPS server. If the size of the key from the server is 512 or 1024 the proxy will select a 1024 key size. If the key size from the servers is over 1024, the proxy will select a key size of 2048.

**CLI changes:**

In `ssl-ssh-profile` remove:

- `certname-rsa`
- `certname-dsa`
- `certname-ecdsa`

In `vpn certificate` setting, add the following options :

- `certname-rsa1024`
- `certname-rsa2048`
- `certname-dsa1024`
- `certname-dsa2048`
- `certname-ecdsa256`
- `certname-ecdsa384`

**AWS API integration for dynamic firewall address object (400265)**

Some new settings have been added to the CLI that will support instance information being retrieved directly from the AWS server. The IP address of a newly launched instance can be automatically added to a certain firewall address group if it meets specific requirements. The new address type is: `ADDR_TYPE_AWS`

**New CLI configuration settings:****The AWS settings**

```

config aws
  set access-key
  set secret-key
  set region

```

```
set vpc-id
set update-interval
```

- access-key - AWS access key.
- secret-key - AWS secret key.
- region - AWS region name.
- vpc-id - AWS VPC ID.
- update-interval - AWS service update interval (60 - 600 sec, default = 60).

### The AWS address:

```
config firewall address
edit <address name>
set type aws
set filter <filter values>
```

The filter can be a combination of any number of conditions, as long as the total length of filter is less than 2048 bytes. The syntax for the filter is:

```
<key1=value1> [& <key2=value2>] [| <key3=value3>]
```

For each condition, it includes a key and value, the supported keys are:

1. instanceId, (e.g. instanceId=i-12345678)
2. instanceType, (e.g. instanceType=t2.micro)
3. imageId, (e.g. imageId=ami-123456)
4. keyName, (e.g. keyName=aws-key-name)
5. architecture, (e.g. architecture=x86)
6. subnetId, (e.g. subnetId=sub-123456)
7. placement.availabilityzone, (e.g. placement.availabilityzone=us-east-1a)
8. placement.groupname, (e.g. placement.groupname=group-name)
9. placement.tenancy, (e.g. placement.tenancy=tenancy-name)
10. privateDnsName, (e.g. privateDnsName=ip-172-31-10-211.us-west-2.compute.internal)
11. publicDnsName, (e.g. publicDnsName=ec2-54-202-168-254.us-west-2.compute.amazonaws.com)
12. AWS instance tag, each tag includes a key and value, the format of tag set is: tag.Name=Value, maximum of 8 tags are supported.

## Internet service configuration (405518)

To make the CLI configuration of Internet service configuration more intuitive, the settings for Internet service in Explicit Web proxy are closer to those in the Firewall police. An Internet service enable switch has been added to the Explicit Web proxy with the same text description as the Firewall policy.

CLI:

The relevant options in the firewall policy are:

```
config firewall policy
edit 1
set internet-service enable
set internet-service-id 327681 1572864 917519 393225 1572888 1572877 917505
```

```
next
end
```

The Explicit Web proxy is now has these options:

```
config firewall proxy-policy
edit 1
set uuid f68e0426-dda8-51e6-ac04-37fc3f92cadf
set proxy explicit-web
set dstintf "port9"
set srcaddr "all"
set internet-service 2686980
set action accept
set schedule "always"
set logtraffic all
next
end
```

## Changes to SSL abbreviate handshake (407544)

The SSL handshake process has changed to make troubleshooting easier.

- In order to better identify which clients have caused SSL errors, the WAD SSL log will use the original source address rather than the source address of packets.
- The return value of `wad_ssl_set_cipher` is checked.
- The `wad_ssl_session_match` has been removed because it will add the connection into bypass cache and bypass further inspection.
- DSA and ECDSA certificates are filtered for `admin-server-cert`
- `cert-inspect` is reset after a WAD match to a Layer 7 policy
- An option to disable the use of SSL abbreviate handshake has been added

## CLI addition

```
config firewall ssl setting
set abbreviate-handshake [enable|disable]
```

## NGFW mode in the VDOM - NAT & SSL Inspection considerations (407547)

Due to how the NGFW Policy mode works, it can get complicated in the two areas of NAT and SSL Deep Inspection. To match an application against a policy, some traffic has to pass through the FortiGate in order to be properly identified. Once that happens may end up getting mapped to a different policy, where the new policy will be appropriately enforced.

### NAT

In the case of NAT being used, the first policy that is triggered to identify the traffic might require NAT enabled for it to work correctly. i.e., without NAT enabled it may never be identified, and thus not fall through. Let's use a very simple example:

Policy 1: Block Youtube

Policy 2: Allow everything else (with NAT enabled)

Any new session established will never be identified immediately as Youtube, so it'll match policy #1 and let some traffic go to try and identify it. Without NAT enabled to the Internet, the session will never be setup and thus stuck here.

**Solution:**

- NAT for NGFW policies must be done via Central SNAT Map
- Central SNAT Map entries now have options for 'srcintf', 'dstintf' and 'action'.
- If no IP-pools are specified in the Central SNAT entry, then the outgoing interface address will be used.
- NGFW policies now must use a single default ssl-ssh-profile. The default ssl-ssh-profile can be configured under the system settings table.

**SSL**

In the case of SSL inspection, the issue is a bit simpler. For each policy there are 3 choices:

1. No SSL,
2. Certificate Only
3. Deep Inspection.

For 1. and 2. there is no conflict and the user could enable them inter-changeably and allow policy fallthrough.

The issue happens when:

- The first policy matched, uses **Certificate Only**
- After the application is detected, it re-maps the session to a new policy which has **Deep Inspection** enabled

This switching of behavior is the main cause of the issue.

**Solution:**

- Multiple SSL profiles have been replaced with a single page of settings
- The user can setup exemptions for destination web category, source IP or etc.

**CLI****Changes**

```
config system settings
  set inspection-mode flow
  set policy-mode [standard | ngfw]
```

Has been changed to:

```
config system settings
  set inspection-mode flow
  set ngfw-mode [profile-based | policy-based]
```

- ngfw-mode - Next Generation Firewall mode.
- profile-based - Application and web-filtering is configured using profiles applied to policy entries.
- policy-based - Application and web-filtering is configured as policy match conditions.

## Additions

### Setting the vdom default ssl-ssh-profile

```
config system settings
  set inspection-mode flow
  set ngfw-mode policy-based
  set ssl-ssh-profile <profile>
```

ssl-ssh-profile - VDOM SSL SSH profile.

### Setting srcintf, dstintf, action on the central-snat policy

```
config firewall central-snat-map
  edit <id>
    set srcintf <names or any>
    set dstintf <names or any>
    set action (permit | deny)
```

- `srcintf` - Source interface name.
- `dstintf` - Destination interface name.
- `action` - Action of central SNAT policy.

## GUI

### System settings, VDOM settings list/dialog:

- A field has been added to show the default `ssl-ssh-profile`

### IPv4/v6 Policy list and dialogs:

- In NGFW policy-based mode, there are added tool tips under NAT columns/fields to indicate that NAT must be configured via Central SNAT Map. Additionally, links to redirect to Central SNAT list were added.
- Default `ssl-ssh-profile` is shown in the policy list and dialog for any policies doing NGFW (`application, application-categories, url-categories`) or UTM (`av-profile etc.`) inspection.
  - Default `ssl-ssh-profile` is disabled from editing in policy list dialog

### Central SNAT Policy list and dialogs:

- In both `profile-based` & `policy-based ngfw-mode`, fields for `srcintf`, `dstintf` were added to Central SNAT policies entries.
- In `policy-based` mode only, a toggle-switch for **NAT Action** was added in Central SNAT policy dialog. The action is also configurable from the **Action** column in Central SNAT policy list.

### SSL/SSH Inspection list:

- In policy-based mode only, the navigation bar link to **SSL/SSH Inspection** redirects to the profiles list
- In policy-based mode only, the **SSL/SSH Inspection** list table indicates which profile is the current VDOM default. Additionally, options are provided in the list menu and context menu to change the current VDOM default.

### Support HTTP policy for flow-based inspection (411666)

It is possible to implement an HTTP-policy in a VDOM that is using the Flow-based inspection mode. Enabling the HTTP-policy causes the traffic to be redirected to WAD so that the traffic can be properly matched and processed.

### Support for CA chain downloading to improve certificate verification (369270)

During certificate verification, if the certificate chain is not complete and CA issuer information exists in the certificate, FortiOS attempts to download intermediate/root CAs from the HTTP server and attempts to perform chain verification. The downloaded CAs are saved in a cache (max 256) to be re-used for future certificate validation. CAs are removed from the cache if they are inactive or not needed for more than 1 hour.

CA chain downloading is used to improve verification results for certificates that are difficult to verify. The CAs are kept in the cache to improve performance.

## Managed FortiSwitch OS 3.6.0 (FortiOS 5.6.3)

New managed FortiSwitch features added to FortiOS 5.6.3 if the FortiSwitch is running FortiSwitch OS 3.6.0.

### Firewall policy now required for RADIUS traffic (434470)

In FortiLink mode, you must manually create a firewall policy to allow RADIUS traffic for 802.1x authentication from the FortiSwitch (for example, from the FortiLink interface) to the RADIUS server through the FortiGate.

### STP root guard (376015)

Enable root guard on all ports that should not be root bridges. Do not enable root guard on the root port. You must have STP enabled to be able to use root guard.

#### Using the FortiGate GUI

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Right-click on a port.
3. Select **Enable** or **Disable**.

#### Using the FortiGate CLI

```
config switch-controller managed-switch
  edit <switch-id>
    config ports
      edit <port name>
        set stp-root-guard {enabled | disabled}
      end
    end
  end
```

### STP BPDU guard (406182)

When BPDU guard is enabled on STP edge ports, any BPDUs received cause the ports to go down for a specified number of minutes. The BPDUs are not forwarded, and the network edge is enforced.

There are two prerequisites for using BPDU guard:

- You must define the port as an edge port with the `set edge-port enable` command.
- You must enable STP on the switch interface with the `set stp-state enabled` command.

### Using the FortiGate GUI

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Right-click on a port.
3. Select **Enable** or **Disable**.

### Using the FortiGate CLI

```
config switch-controller managed-switch
  edit <switch-id>
    config ports
      edit <port name>
        set stp-bpdu-guard {enabled | disabled}
        set stp-bpdu-guard-time <0-120>
      end
    end
  end
```

### FortiSwitch log message changes (438738)

More details are now provided in exported FortiSwitch logs, for example:

- New Switch-Controller user field and daemon-name ui fields.
- Removed Switch-Controller keyword from the msg field
- Changed UpdSwConf keyword in msg field to FortiSwitch in flcfgd logs
- Removed the VDOM keyword from the msg field in flcfgd logs
- Removed the Fortiswitch keyword before SN in the msg field
- Changed syslog to have switch SN first followed by a space and then the first word following with a capital (in the msg field)

Use the following CLI commands to enable the export of FortiSwitch logs and to set the level of logging included. The system logs all messages at and above the logging severity level you select. For example, if you select `error`, the system logs `error`, `critical`, `alert`, and `emergency` level messages.

```
config switch-controller switch-log
  set status (*enable | disable)
  set severity [emergency | alert | critical | error | warning | notification |
    *information | debug]
end
```

### Support FSW BPDU Guard (442921) (442922)

With standard STP, a device that sends BPDU(s) to any switch port becomes a member of that switch's STP network topology. In order to enforce a network edge, the access ports on the switch can be configured with BPDU guard. With BPDU guard enabled, the port does not forward BPDUs upstream (toward its root bridge). Instead, when a BPDU guard enabled port receives any BPDU, it immediately puts the port into a blocking state and alerts the user.

This prevents the access port from accepting the downstream device, removing it from the receiving switch's STP calculations. In order to unblock the port after bpdu guard has triggered, the user must execute a reset command.

After the port is reset, it will resume normal operation and return to a blocking state only if another BPDU is received.

BPDU guard is typically used in conjunction with Root Guard to enforce a specific network topology.

### Syntax

```
config switch-controller managed-switch
  edit <switch SN>
    config ports
      edit <port>
        set stp-bpdu-guard <enable | *disable>
        set stp-bpdu-guard-timeout <time> (0-120 in minutes)
      next
    end
  next
end

config switch-controller managed-switch
  edit <switch SN>
    config ports
      edit <port>
        set stp-root-guard <enable | *disable>
      next
    end
  next
end

diagnose switch-controller dump stp <switch SN> <instance>
diagnose switch-controller bpdu-guard-status <switch SN>
```

### Managed switch CLI features added to GUI (448722)

Added new optional columns "Edge Port", "LLDP Profile", "QoS Policy", "STP BPDU Guard", "STP Root Guard" in **WiFi & Switch Controller > FortiSwitch Ports**.

This would allow administrators to make changes to the features above to multiple switch ports at the same time.

### Added unit in help-text when setting max-rate/min-rate under switch-controller qos queue-policy (449487) (449869)

Modified the CLI help-text on the FortiGate to show priority under strict schedule when setting max-rate/min-rate under switch-controller qos queue-policy.

### Syntax

```
set priority-0
  queue-0 COS queue 0. (lowest priority)
  queue-1 COS queue 1.
  queue-2 COS queue 2.
  queue-3 COS queue 3.
  queue-4 COS queue 4.
  queue-5 COS queue 5.
  queue-6 COS queue 6.
  queue-7 COS queue 7. (highest priority)
```

## Added FortiSwitch factory-reset functionality to the FortiOS GUI (393205)

Added a **Factory Reset** button to the **WiFi & Switch Controller > Managed FortiSwitch** page when a FortiSwitch document is selected.

### Syntax

```
execute switch-controller factory-rest <switch sn>
```

## Managed FortiSwitch OS 3.6.0 (FortiOS 5.6.1)

New managed FortiSwitch features added to FortiOS 5.6.1 if the FortiSwitch is running FortiSwitch OS 3.6.0.

### Simplified method to convert a FortiSwitch to standalone mode (393205)

There is an easier way to convert a FortiSwitch from FortiLink mode to standalone mode so that it will no longer be managed by a FortiGate:

- `execute switch-controller factory-reset <switch-id>`  
This command returns the FortiSwitch to the factory defaults and then reboots the FortiSwitch. If the FortiSwitch is configured for FortiLink auto-discovery, FortiGate can detect and automatically authorize the FortiSwitch.
- `execute switch-controller set-standalone <switch-id>`  
This command returns the FortiSwitch to the factory defaults, reboots the FortiSwitch, and prevents the FortiGate from automatically detecting and authorizing the FortiSwitch.

You can disable FortiLink auto-discovery on multiple FortiSwitches using the following commands:

```
config switch-controller global
  set disable-discovery <switch-id>
end
```

You can also add or remove entries from the list of FortiSwitches that have FortiLink auto-discovery disabled using the following commands:

```
config switch-controller global
  append disable-discovery <switch-id>
  unselect disable-discovery <switch-id>
end
```

## Quarantines (410828)

Quarantined MAC addresses are blocked on the connected FortiSwitches from the network and the LAN.

**NOTE:** You must enable the quarantine feature in the FortiGate CLI using the `set quarantine enable` command. You can add MAC addresses to the quarantine list before enabling the quarantine feature, but the quarantine does not go into effect until enabled.

### Quarantining a MAC address

#### Using the FortiGate GUI

1. Select the host to quarantine.
  - Go to **Security Fabric > Physical Topology**, right-click on a host, and select **Quarantine Host on FortiSwitch**.

- Go to **Security Fabric > Logical Topology**, right-click on a host, and select **Quarantine Host on FortiSwitch**.
- Go to **FortiView > Sources**, right-click on an entry in the Source column, and select **Quarantine Host on FortiSwitch**.

2. Click **OK** to confirm that you want to quarantine the host.

### Using the FortiGate CLI

```
config switch-controller quarantine
  set quarantine enable
  edit <MAC_address>
    set description <string>
    set tags <tag1 tag2 tag3 ...>
  next
next
end
```

Option	Description
MAC_address	A layer-2 MAC address in the following format: 12:34:56:aa:bb:cc
string	Optional. A description of the MAC address being quarantined.
tag1 tag2 tag3 ...	Optional. A list of arbitrary strings.

### Viewing quarantine entries

Quarantine entries are created on the FortiGate that is managing the FortiSwitch.

### Using the FortiGate GUI

1. Go to **Monitor > Quarantine Monitor**.
2. Click **Quarantined on FortiSwitch**.

### Using the FortiGate CLI

Use the following command to view the quarantine list of MAC addresses:

```
show switch-controller quarantine
```

When the quarantine feature is enabled on the FortiGate, it creates a quarantine VLAN (qtn.<FortiLink\_port\_name>) on the virtual domain. The quarantine VLAN is applied to the allowed and untagged VLANs on all connected FortiSwitch ports.

Use the following command to view the quarantine VLAN:

```
show system interface qtn.<FortiLink_port_name>
```

Use the following command to view how the quarantine VLAN is applied to the allowed and untagged VLANs on all connected FortiSwitch ports:

```
show switch-controller managed-switch
```

## Releasing MAC addresses from quarantine

### Using the FortiGate GUI

1. Go to **Monitor > Quarantine Monitor**.
2. Click **Quarantined on FortiSwitch**.
3. Right-click on one of the entries and select **Delete** or **Remove All**.
4. Click **OK** to confirm your choice.

### Using the FortiGate CLI

Use the following commands to delete a quarantined MAC address:

```
config switch-controller quarantine
config targets
    delete <MAC_address>
end
```

When the quarantine feature is disabled, all quarantined MAC addresses are released from quarantine. Use the following commands to disable the quarantine feature:

```
config switch-controller quarantine
    set quarantine disable
end
```

## Assign untagged VLANs to a managed FortiSwitch port (410828)

Use the following commands to assign untagged VLANs to a managed FortiSwitch port:

```
config switch-controller managed-switch
    edit <managed-switch>
        config ports
            edit <port>
                set untagged-vlans <VLAN-name>
            next
        end
    next
end
```

## View, create, and assign multiple 802.1X policy definitions (408389 and 403901)

Previously, you could create one 802.1X policy for all managed FortiSwitches in a virtual domain. Now, you can create multiple 802.1X policies and assign a different 802.1X policy to each managed FortiSwitch port.

### View security policies for managed FortiSwitches

You can view security policies for managed FortiSwitches in two places:

- Go to **WiFi & Switch Controller > FortiSwitch Security Policies**.
- Go to **WiFi & Switch Controller > FortiSwitch Ports** and click the **+** next to a FortiSwitch. The security policy for each port is listed in the Security Policy column.

## Create and assign multiple 802.1X policy definitions for managed FortiSwitches

Previously, you could create one 802.1X policy for all managed FortiSwitches in a virtual domain. Now, you can create multiple 802.1X policies and assign a different 802.1X policy to each managed FortiSwitch port.

### To create an 802.1X security policy:

1. Go to **WiFi & Switch Controller > FortiSwitch Security Policies**.
2. Click **Create New**.
3. Enter a name for the new FortiSwitch security policy.
4. For the security mode, select **Port-based** or **MAC-based**.
5. Click **+** to select which user groups will have access.
6. Enable or disable guest VLANs on this interface to allow restricted access for some users.
7. Enter the number of seconds for authentication delay for guest VLANs. The range is 60-900 seconds.
8. Enable or disable authentication fail VLAN on this interface to allow restricted access for users who fail to access the guest VLAN.
9. Enable or disable MAC authentication bypass (MAB) on this interface.
10. Enable or disable EAP pass-through mode on this interface.
11. Enable or disable whether the session timeout for the RADIUS server will overwrite the local timeout.
12. Click **OK**.

### To apply an 802.1X security policy to a managed FortiSwitch port:

1. Go to **WiFi & Switch Controller > FortiSwitch Ports**.
2. Click the **+** next to a FortiSwitch.
3. In the Security Policy column for a port, click **+** to select a security policy.
4. Click **OK** to apply the security policy to that port.

## Override 802.1X settings

### To override the 802.1X settings for a virtual domain:

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Click on a FortiSwitch faceplate and click **Edit**.
3. In the Edit Managed FortiSwitch page, move the **Override 802-1X settings** slider to the right.
4. In the Reauthentication Interval field, enter the number of minutes before reauthentication is required. The maximum interval is 1,440 minutes. Setting the value to 0 minutes disables reauthentication.
5. In the Max Reauthentication Attempts field, enter the maximum times that reauthentication is attempted. The maximum number of attempts is 15. Setting the value to 0 disables reauthentication.
6. Select **Deauthenticate** or **None** for the link down action. Selecting **Deauthenticate** sets the interface to unauthenticated when a link is down, and reauthentication is needed. Selecting **None** means that the interface does not need to be reauthenticated when a link is down.
7. Click **OK**.

## Enable and disable switch-controller access VLANs through FortiGate (406718)

Access VLANs are VLANs that aggregate client traffic solely to the FortiGate. This prevents direct client-to-client traffic visibility at the layer-2 VLAN layer. Clients can only communicate with the FortiGate. After the client traffic

reaches the FortiGate, the FortiGate can then determine whether to allow various levels of access to the client by shifting the client's network VLAN as appropriate.

Use `enable` to allow traffic only to and from the FortiGate and to block FortiSwitch port-to-port traffic on the specified VLAN. Use `disable` to allow normal traffic on the specified VLAN.

```
config system interface
  edit <VLAN name>
    set switch-controller-access-vlan {enable | disable}
  next
end
```

### Override the admin password for all managed FortiSwitches (416261)

By default, each FortiSwitch has an admin account without a password. To replace the admin passwords for all FortiSwitches managed by a FortiGate, use the following commands:

```
config switch-controller switch-profile
  edit default
    set login-passwd-override {enable | disable}
    set login-passwd <password>
  next
end
```

If you had already applied a profile with the override enabled and the password set and then decide to remove the admin password, you need to apply a profile with the override enabled and use the `unset login-passwd` command; otherwise, your previously set password will remain in the FortiSwitch.

### Configure an MCLAG with managed FortiSwitches (366617)

To configure a multichassis LAG (MCLAG) with managed FortiSwitches:

1. For each MCLAG peer switch, log into the FortiSwitch to create a LAG:

```
config switch trunk
  edit "LAG-member"
    set mode lacp-active
    set mclag-icl enable
    set members "<port>" "<port>"
  next
```

## 2. Enable the MCLAG on each managed FortiSwitch:

```
config switch-controller managed-switch
  edit "<switch-id>"
    config ports
      edit "<trunk name>"
        set type trunk
        set mode {static | lacp-passive | lacp-active}
        set bundle {enable | disable}
        set members "<port>,<port>"
        set mclag {enable | disable}
      next
    end
  next
```

## 3. Log into each managed FortiSwitch to check the MCLAG configuration:

```
diagnose switch mclag
```

After the FortiSwitches are configured as MCLAG peer switches, any port that supports advanced features on the FortiSwitch can become a LAG port. When `mclag` is enabled and the LAG port names match, an MCLAG peer set is automatically formed. The member ports for each FortiSwitch in the MCLAG do not need to be identical to the member ports on the peer FortiSwitch.

## Configure QoS with managed FortiSwitches (373581)

Quality of Service (QoS) provides the ability to set particular priorities for different applications, users, or data flows. **NOTE:** FortiGate does not support QoS for hard or soft switch ports.

### To configure the QoS for managed FortiSwitches:

#### 1. Configure a Dot1p map.

```
config switch-controller qos dot1p-map
  edit <Dot1p map name>
    set description <text>
    set priority-0 <queue number>
    set priority-1 <queue number>
    set priority-2 <queue number>
    set priority-3 <queue number>
    set priority-4 <queue number>
    set priority-5 <queue number>
    set priority-6 <queue number>
    set priority-7 <queue number>
  next
end
```

#### 2. Configure a DSCP map.

```
config switch-controller qos ip-dscp-map
  edit <DSCP map name>
    set description <text>
    configure map <map_name>
      edit <entry name>
        set cos-queue <COS queue number>
```

```

        set diffserv {CS0 | CS1 | AF11 | AF12 | AF13 | CS2 | AF21 | AF22 | AF23
          | CS3 | AF31 | AF32 | AF33 | CS4 | AF41 | AF42 | AF43 | CS5 | EF |
          CS6 | CS7}
        set ip-precedence {network-control | internetwork-control | critic-ecp
          | flashoverride | flash | immediate | priority | routine}
        set value <DSCP raw value>
      next
    end
  end
end

```

### 3. Configure the egress QoS policy.

```

config switch-controller qos queue-policy
  edit <QoS egress policy name>
    set schedule {strict | round-robin | weighted}
    config cos-queue
      edit [queue-<number>]
        set description <text>
        set min-rate <rate in kbps>
        set max-rate <rate in kbps>
        set drop-policy {taildrop | random-early-detection}
        set weight <weight value>
      next
    end
  next
end

```

### 4. Configure the overall policy that will be applied to the switch ports.

```

config switch-controller qos qos-policy
  edit <QoS egress policy name>
    set default-cos <default CoS value 0-7>
    set trust-dot1p-map <Dot1p map name>
    set trust-ip-dscp-map <DSCP map name>
    set queue-policy <queue policy name>
  next
end

```

### 5. Configure each switch port.

```

config switch-controller managed-switch
  edit <switch-id>
    config ports
      edit <port>
        set qos-policy <CoS policy>
      next
    end
  next
end

```

## Reset PoE-enabled ports from the GUI (387417)

If you need to reset PoE-enabled ports, go to **WiFi & Switch Control > FortiSwitch Ports**, right-click on one or more PoE-enabled ports and select **Reset PoE** from the context menu.

You can also go to **WiFi & Switch Control > Managed FortiSwitch** and click on a port icon for the FortiSwitch of interest. In the FortiSwitch Ports page, right-click on one or more PoE-enabled ports and select **Reset PoE** from the context menu.

### Adding preauthorized FortiSwitches (382774)

After you preauthorize a FortiSwitch, you can assign the FortiSwitch ports to a VLAN.

#### To preauthorize a FortiSwitch:

1. Go to **WiFi & Switch Controller > Managed FortiSwitch**.
2. Click **Create New**.
3. In the New Managed FortiSwitch page, enter the serial number, model name, and description of the FortiSwitch.
4. Move the **Authorized** slider to the right.
5. Click **OK**.

The Managed FortiSwitch page shows a FortiSwitch faceplate for the preauthorized switch.

### Managed FortiSwitch OS 3.6.0 (FortiOS 5.6)

New managed FortiSwitch features added to FortiOS 5.6 if the FortiSwitch is running FortiSwitch OS 3.6.0.

#### IGMP snooping (387515)

The GUI and CLI support the ability to configure IGMP snooping for managed switch ports.

To enable IGMP snooping from the GUI, go to **WiFi & Switch Controller > FortiSwitch VLANs**, edit a VLAN and turn on **IGMP Snooping** under **Networked Devices**.

From the CLI, start by enabling IGMP snooping on the FortiGate:

```
config switch-controller igmp-snooping
  set aging-time <int>
  set flood-unknown-multicast (enable | disable)
end
```

Then enable IGMP snooping on a VLAN:

```
config system interface
  edit <vlan>
    set switch-controller-igmp-snooping (enable | disable)
  end
```

Use the following command to enable IGMP snooping on switch ports, and to override the global parameters for a specific switch.

```
config switch-controller managed-switch
  edit <switch>
    config ports
      edit port <number>
        set igmp-snooping (enable | disable)
        set igmps-flood-reports (enable | disable)
      next
    config igmp-snooping globals
      set aging-time <int>
      set flood-unknown-multicast (enable | disable)
    end
  next
```

end

### User-port link aggregation groups (378470)

The GUI now supports the ability to configure user port LAGs on managed FortiSwitches.

**To create a link aggregation group for FortiSwitch user ports:**

1. Go to **WiFi & Switch Controller > FortiSwitch Ports**
2. Click **Create New > Trunk**.
3. In the New Trunk Group page:
  - a. Enter a name for the trunk group
  - b. Select two or more physical ports to add to the trunk group
  - c. Select the mode: Static, Passive LACP, or Active LACP
4. Click **OK**.

### DHCP blocking, STP, and loop guard on managed FortiSwitch ports (375860)

The managed FortiSwitch GUI now supports the ability to enable/disable DHCP blocking, STP and loop guard for FortiSwitch user ports.

Go to **WiFi & Switch Controller > FortiSwitch Ports**. For any port you can select DHCP Blocking, STP, or Loop Guard. STP is enabled on all ports by default. Loop guard is disabled by default on all ports.

### Switch profile enhancements (387398)

Default switch profiles are bound to every switch discovered by the FortiGate. This means that an administrator can establish a password for this profile or create a new profile and bind that profile to any switch. Consequently, the password provided shall be configured on the FortiSwitch against the default "admin" account already present.

### Number of switches per FortiGate based on model (388024)

The maximum number of supported FortiSwitches depends on the FortiGate model:

FortiGate Model Range	Number of FortiSwitches Supported
Up to FortiGate-98 and FortiGate-VM01	8
FortiGate-100 to 280 and FortiGate-VM02	24
FortiGate-300 to 5xx	48
FortiGate-600 to 900 and FortiGate-VM04	64
FortiGate-1000 and up	128
FortiGate-3xxx and up, and FortiGate-VM08 and up	256

### Miscellaneous configuration option changes

- The default value of `dhcp-snooping` (also called DHCP-blocking) is changed from `trusted` in FortiOS 5.4 to `untrusted` in FortiOS 5.6.

- The default value of `edge-port` is changed from `disabled` in FortiOS 5.4 to `enabled` in FortiOS 5.6.0.
- The default value for DHCP snooping on the FortiLink VLAN (system interface) is changed from “enabled” in FortiOS 5.6.2 and earlier to “disabled” in FortiOS 5.6.3 and later. Note that, in the GUI, DHCP snooping is automatically changed to “enable” when the DHCP server is enabled on the interface.

### Additional GUI support

- Link aggregation of FortiSwitch ports
- DHCP trusted/untrusted, loop guard, and STP for FortiSwitch ports
- Connect to CLI support for FortiSwitch

## FortiView (5.6.3)

New FortiView features added to FortiOS 5.6.3.

### Support learning reports and FortiAnalyzer (415806)

Both backend and GUI have been updated to support learning reports from FortiAnalyzer.

Backend updates the query configure list; GUI updates learning report to use log display device setting.

### Added support to FortiView to sort by application risk and browsing time (249666)

Added ability to sort applications by threat level and by browsing time so that admin can quickly see and prioritize the riskier applications at the top of the list.

## FortiView (5.6.1)

New FortiView features added to FortiOS 5.6.1.

### FortiView Dashboard Widget (434179)

A new widget type has been added to the FortiGate Dashboard, that displays compact FortiView data. Supported FortiViews include Source, Destination, Application, Country, Interfaces, Policy, Wifi Client, Traffic Shaper, Endpoint Vulnerability, Cloud User, Threats, VPN, Websites, Admin, and System. All usual visualizations are supported.

Widgets can be saved directly to the Dashboard from a filtered page in FortiView, or configured in the CLI.

### Interface Categories (`srcintfrole`, etc) added to log data (434188)

In 5.6, logs and FortiView both sort log traffic into two interface categories: "Traffic from LAN/DMZ", and "Traffic from WAN." For greater compatibility and troubleshooting of FortiAnalyzer and FortiCloud setups, interface category fields that expose this information have been added to general log data in 5.6.1: `srcintfrole` and `dstintfrole` for better backend control and monitoring.

## FortiView (5.6)

New FortiView features added to FortiOS 5.6.

### Added Vulnerability score topology view (303786)

In **Physical Topology** and **Logical Topology** pages, there are two new views added: **Vulnerability**, and **Threat**. Drill-downs in these menus will now include Vulnerability/Threat information. In Vulnerability view, device bubbles are colored based on maximum vulnerability level, and bubble size is the vulnerability score. In Threat view, device bubbles are colored based on maximum threat level, and bubble size is the threat score.

### FortiView VPN tunnel map feature (382767)

The FortiView VPN page now displays VPN tunnel connections between devices, and offers more information about tunnels and devices on drill-down.

### Updated FortiView CSF topology pages (384188)

The FortiView **Physical Topology** and **Logical Topology** pages have been updated in 5.6.0 to reorganize and clarify larger deployments with servers and multi-directional traffic.

### Historical FortiView includes FortiAnalyzer (387423)

Data from associated FortiAnalyzer devices can now be selected as a log display option for Historical FortiView.

### FortiView menu reorganization (399713)

The order of FortiView pages has been reorganized in 5.6.0 based on the source interface of data being displayed:

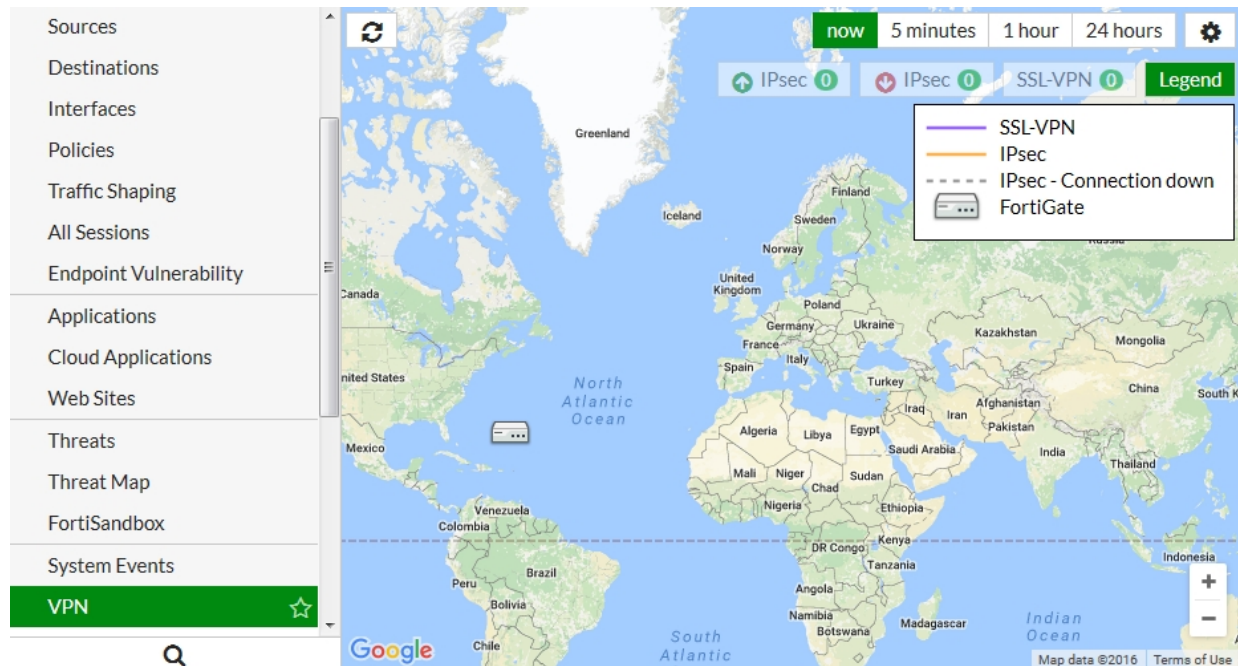

- Topology
- Traffic from LAN/DMZ
- Traffic from WAN
- All Segments

### Data Exchange with FortiAnalyzer (393891)

Rather than sending all CSF information via log messages, FortiGate and FortiAnalyzer will now directly pass CSF information (tree, interface roles, user devices, HA members), if the FAZ responds to notices that are sent when the data has changed.

### Google Maps Integration

FortiView now uses Google Maps to display location-related information. In this release the first view to use Google maps this component is the FortView VPN page. All current VPNs can be viewed on a fully scalable Google world map.

### FortiView usability and organization updates (306247)

Several organization changes have been made to make the FortiView menu order less cluttered, and more intuitive.

- **WiFi Client Monitor** is now in FortiView, but is hidden when there is no managed FortiAP or WiFi Radio.
- **Country** view has been merged into **Destinations** view.
- **Failed Authentication** and **Admin Login** views have been merged into **System Events** view.

## FortiGate VM enhancements for AWS, Azure, Google, SDN connectors and more (5.6.3)

The realm of virtual computing has become mainstream and not only does this mean that security appliances can also be virtual, there is also a requirement for security appliances in a virtual environment. These environments can be the publicly available platforms such as Amazon Web Services, Azure and Google Cloud Platform or they can be Software Defined Networks (SDN) such as those made by Cisco, HP, Nuage and OpenStack. For that reason, not only is the number of Virtual FortiOS variations growing along with what they can do, a number of the new features being introduced deal with integrating FortiOS into these environments.

In some cases the new feature isn't even part of the FortiOS code but a separate piece of software that not only allows the FortiOS-VM to be part of the virtual environment but allows the management software of the environment to manage the FortiOS-VM. Previously, these connectors to SDNs have been treated separately as specialized products with their own documentation. Because they are so integral to FortiOS in a world where virtual computing is becoming normal, this documentation is going to become more integrated into the normal FortiOS documentation.

Recipes are now being published for the cloud-based and SDN environments on the Fortinet Cookbook website.

- <http://cookbook.fortinet.com/amazon-web-services-aws/>
- <http://cookbook.fortinet.com/cisco-aci/>
- <http://cookbook.fortinet.com/microsoft-azure/>
- <http://cookbook.fortinet.com/nuage-vsp/>

## FGT\_VM64\_AZURE and FGT\_VM64\_AZUREONDEMAND platforms (356702)

FortiOS runs in the Azure Cloud and supports the Azure Security Center NGFW feature. The `waagent` daemon is used to configure the VM to communicate with the Azure Cloud fabric.

- The kernel UDF filesystem is needed to mount the cdrom disc on first boot.
- `libxml` is upgraded from v2.9 to v2.10

### CLI Changes:

Added: `azure-security-center` logging destination

```
config log [azure-security-center | azure-security-center2]
  config filter
    set status [enable | disable]
    set appliance-id
    set policy-saskey
    set policy-name
    set eventhub-name
    set servicebus-namespace
  config setting
    set severity (see below)
    set forward-traffic [enable | disable]
    set local-traffic [enable | disable]
    set multicast-traffic [enable | disable]
    set sniffer-traffic [enable | disable]
    set anomaly [enable | disable]
    set voip [enable | disable]
    set gtp [enable | disable]
    set dns [enable | disable]
    set filter (see below)
```

```
set filter-type [include | exclude]
```

`severity` option includes the following levels of severity notifications:

- emergency
- alert
- critical
- error
- warning
- notification
- information
- debug

The `filter` option is set by included the logid list and/or its level as filters. Possibilities include:

- logid(...)
- traffic-level(...)
- event-level(...)
- virus-level(...)
- webfilter-level(...)
- ips-level(...)
- emailfilter-level(...)
- anomaly-level(...)
- voip-level(...)
- dlp-level(...)
- app-ctrl-level(...)
- waf-level(...)
- gtp-level(...)
- dns-level(...)

#### Example 1

```
config log azure-security-center
config setting
set filter "logid(40704,32042)"
```

#### Example 2

```
config log azure-security-center
config setting
set filter "event-level(information)"
```

The available levels are as the following: emergency, alert, critical, error, warning, notice, information, debugdebug

### SDN Connector (404907)

FortiOS-VM is now supported in a Cisco ACI environment through the use of a SDN connector. The software can be found on the [Fortinet Service and Support site](#). The product name is FortiADC-Connector. Documentation can be found on the [Fortinet Documentation site](#) under the product heading of Fortinet Connectors

## FortiGate-VM performance improvements and optimization (416548)

Performance has been improved for FortiOS VM platforms by implementing new features to improve efficiency and resource utilization. As well, you can now configure interrupt affinity and packet distribution to optimize performance for your VM environment. Interrupt affinity allows you to align interrupts from interfaces to specific CPUs. Packet distribution allows you to configure FortiGate-VM to distribute processing to multiple CPUs.

### Configuring interrupt affinity

Use the following commands to configure interrupt affinity for two 10G interfaces (port2 and port3).

Interrupts from first interface are assigned to core #0 and those from the second interface are assigned to core #1.

```
config system affinity-interrupt
  edit 1
    set interrupt "port2-TxRx-0"
    set affinity-cpumask "0x1"
  next
  edit 2
    set interrupt "port2-TxRx-1"
    set affinity-cpumask "0x1"
  next
  edit 3
    set interrupt "port3-TxRx-0"
    set affinity-cpumask "0x2"
  next
  edit 4
    set interrupt "port3-TxRx-1"
    set affinity-cpumask "0x2"
end
```

### Configuring packet distribution

Use the following commands to configure packet redistribution to redistribute packets from core #0 and #1 to all other cores.

The example is based on VM08:

```
config system affinity-packet-redistribution
  edit 1
    set interface "port2"
    set affinity-cpumask "0xFC"
  next
  edit 2
    set interface "port3"
    set affinity-cpumask "0xFC"
end
```

## FortiGate-VM Models available for Google Cloud Platform (GCP) (422209)

The following FortiGate-VM models will be supported on Google Cloud Platform:

- FG-VM01
- FG-VM02

- FG-VM04
- FG-VM08

FG-WM00 is not supported.

Since GCP use netmask 32, static route must be configured on GCP VPC, instead of FGT.

Licenses will be interchangeable between platforms. A FG-VM04 license that functions in a VMware or Citrix environment can be also used in the GCP environment as well.

While an .out file will be necessary for upgrading, full downloadable images will not be needed for initial installation of the solution. GCP consists of pre-existing images that can be checked out of their library and deployed instantly. A difference between this environment and enterprise virtualization platforms is that machine size can never change. An n1-standard-4 has exactly 15 GB of RAM and 4 vCPUs. This can never be changed or edited by the end user or administrator.

The currently available GCP instances we are looking to support are as follows (these will/could change as vNIC values reveal themselves):

FG-VM	Equates to Instance Type	vCPU	RAM	Disks
FG-VM01-GC	n1-standard-1	1	3.75GB	16 (32 in Beta)
FG-VM02-GC	n1-standard-2	2	7.50 GB	16 (64 in Beta)
FG-VM04-GC	n1-standard-4	4	15 GB	16 (64 in Beta)
FG-VM08-GC	n1-standard-8	8	30 GB	16 (128 in Beta)
FG-VM16-GC	n1-standard-16	16	60 GB	16 (128 in Beta)
FG-VM32-GC	n1-standard-32	32	88 GB	16 (128 in Beta)
FG-VMUL-GC	any of the above and any new that could be created.			

Additional information from GCP: <https://cloud.google.com/compute/docs/images/building-custom-os>.

### NPU KVM image for FortiHypervisor (435326)

Currently, there are 2 separate images of FortiOS that can run on FortiHypervisor:

1. Standard KVM image -- this is the one all customers have access to via the Fortinet Support site and FortiGuard
2. NPU support image -- this is a special branch, not available on support site or FortiGuard.

When FHV tries to deploy a VM that it gets from FortiGuard, it can only retrieve #1 but not #2. NPU versions are now supported by and available for FortiHypervisor.

### FGT-VM AWS HA support (445721)

FortiGate-VMs in an Amazon Web Services environment support the use of HA.

This includes two parts:

1. HA with unicast heartbeat traffic.
2. AWS API supports to move secondary IPs and update routing tables.

**CLI Changes:**

Add: Unicast HA config

```
config system ha
    unicast-hb [enable|disable]
    unicast-hb-peerip <Unicast Heartbeat Peer IP>
end
```

**Closed-Network FGT-VM (451872) (455174)**

FortiGate-VM is not part of the FortiGuard Network for the purpose of upgrades.

**Logging enhancements on FG-VMX (452701)**

An event log is created when the Service Manager loses connectivity to a VMX instance. A unique serial number should be used for each VMX instance so that users can identify from the log which VMX instance is described.

**SDN Connector - AWS (454233)**

Improvements have been made in the support of FortiGate-VM integrating into the AWS environment.

1. `config aws setting` has been moved to the context of `config system sdn-connector`.  

```
config system sdn-connector
    edit <string>
        set access-key <AWS access key ID>
        set secret-key <AWS secret access key>
        set region <AWS region name>
        set vpc-id <AWS VPC ID>
    end
```
2. Update to the GUI SDN connector edit page that supports allowing configuration of the following fields:
  - AWS access key ID
  - AWS secret access key
  - AWS region name
  - AWS VPC ID
  - Update Interval
3. Change to address edit page to allow configuration of the **Filter** field for Dynamic AWS address.
4. Update to the dynamic address monitor API to get resolved address list for dynamic AWS addresses.

**NSX Connector Upgrade Support (454674) (458180)**

Support for NSX connector upgrade to SDN connectors.

**Change to `config system sdn-connector`:**

```
config nsx setting
```

**Change to `config firewall address`:**

```
set type nsx

set type dynamic
    set sdn nsx
```

When using the sdn nsx setting, the user should also use the nsx rest-api password.

### GUI fixes for the SDN Connector (458183) (459079) (459081)

- Update address list and policy list to show icon/tooltip of the dynamic address, the same way as FQDN address does.

#### Updates to SDN connector page

- Add back the **Enable Service** button from SVM Settings page (SVM only)
- Add back **VMX Statistics** list from SVM Settings page (SVM only)
- Add back api monitor for nsx service (SVM only)
- Remove **SVM Settings** page

#### Updates to Address List page

- Disable clone context menu for dynamic sdn address
- Add dynamic address details in colored labels
- Add tool-tip to name column; show invalid icon for unresolved dynamic address (the same way as FQDN address)

#### Update Policy List page

- add tool-tip to name column; show invalid icon for unresolved dynamic address (the same way as FQDN address)

## FortiGate VM (5.6.0)

New Virtual FortiOS features added to FortiOS 5.6.0.

### FGT-VM VCPUs (308297)

Fortinet has now launched licensing for FortiGate VMs that support larger than 8 vCPUs. The new models/licenses include:

- Support for up to 16 vCPU - FortiGate-VM16
- Support for up to 32 vCPU - FortiGate-VM32
- Support for unlimited vCPU - FortiGate-VMUL

Each of these models should be able to support up to 500 VDOMs.

### Improvements to License page (382128)

The page has been rewritten with some minor improvements such as:

- An indicator to show when a VM is waiting for authentication or starting up
- Shows VM status when license is valid
- Shows CLI console window when VM is waiting too long for remote registration of server

### Citrix XenServer tools support for XenServer VMs (387984)

This support allows users, with Citrix XenServer tools to read performance statistics from XenServer clients and do Xenmotion with servers in the same cluster

Since FortiGates don't support hardware hotplugging, the ability to do network interface of disk changes is not supported at this time.

---

There are no changes to the GUI, but there are some changes to the CLI.

A setting has been edited to control the debug level of the XenServer tools daemon

```
diag debug application xstoolsd <integer>
```

Integer = Debug level

An additional update has been added to set the update frequency for XenServer tools

```
config system global
  set xstools-update-frequency Xenserver <integer>
end
```

Enter an integer value from 30 to 300 (default = 60).

### **FOS VM supports more interfaces (393068)**

The number of virtual interfaces that the VM version of FortiOS supports has been raised from 3 to 10.

### **NSX security group importing (403975)**

A feature has been added to allow the importation of security group information from VMware's NSX firewall.

#### **CLI Changes:**

##### **nsx group list**

This is used to list NSX security Groups

##### **Syntax:**

```
execute nsx group list <name of the filter>
```

##### **nsx group import**

This is used to import NSX security groups.

##### **Syntax:**

```
execute nsx group import <vdom> <name of the filter>
```

##### **nsx group delete**

This is used to delete NSX security Groups

##### **Syntax:**

```
execute nsx group delete <vdom> <name of the filter>
```

**nsx.setting.update-period**

This is used to set the update period for the NSX security group

**Syntax:**

```
config.nsx.setting.update-period <0 - 3600 in seconds>
```

0 means disabled

**Default value:** 0

**Non-vdom VM models FGVM1V/FGVM2V/FGVM4V (405549)**

New models of the FortiGate-VM have been introduced. These match up with the existing FortiGate-VM models of FG-VM01, FG-VM02 and FG-VM04. The difference being that the new models don't support VDOMs.

Original FortiGate-VM	New FortiGate-VM without VDOM support
FG-VM01	FG-VM01v
FG-VM02	FG-VM02v
FG-VM04	FG-VM04v

### Hardware acceleration (5.6.3)

New hardware acceleration features added to FortiOS 5.6.3.

#### Bandwidth control between the ISF and NP6 XAUI ports (437911)

In some cases, the Internal Switch Fabric (ISF) buffer size may be larger than the buffer size of an NP6 XAUI port that receives traffic from the ISF. If this happens, burst traffic from the ISF may exceed the capacity of an XAUI port and sessions may be dropped.

You can use the following command to configure bandwidth control between the ISF and XAUI ports. Enabling bandwidth control can smooth burst traffic and keep the XAUI ports from getting overwhelmed and dropping sessions.

Use the following command to enable bandwidth control:

```
config system npu
    set sw-np-bandwidth {0G | 2G | 4G | 5G | 6G}
end
```

The default setting is 0G which means no bandwidth control. The other options limit the bandwidth to 2Gbps, 4Gbps and so on.

#### SNMP/CLI monitoring capabilities of NP6 session table and session drift (441532)

In some cases sessions processed by NP6 processors may fail to be deleted leading to a large number of idle sessions. This is called session drift. New monitoring capabilities have been added to allow you to use SNMP to be alerted when the number of idle sessions becomes high. The SNMP fields allow you to see which NP6 processor has the abnormal number of idle sessions and you can use a diagnose command to delete them.

You can use the following diagnose command to determine if drift is occurring:

```
diagnose npu np6 sse-drift-summary
NPU    drv-drift
-----
np6_0  0
np6_1  0
-----
Sum    0
-----
```

The command output shows a drift summary for all the NP6 processors in the system, and shows the total drift. Normally the sum is 0. The previous command output, from a FortiGate-1500D, shows that the 1500D's two NP6 processors are not experiencing any drift.

If the sum is not zero, then extra idle sessions may be accumulating. You can use the following command to delete those sessions:

```
diagnose npu np6 sse-purge-drift <np6_id> [<time>]
```

Where <np6\_id> is the number (starting with NP6\_0 with a np6\_id of 0) of the NP6 processor for which to delete idle sessions. <time> is the age in seconds of the idle sessions to be deleted. All idle sessions this age and older are deleted. The default time is 300 seconds.

The `diagnose npu np6 sse-stats <np6_id>` command output also includes a `drv-drift` field that shows the total drift for one NP6 processor.

For SNMP monitoring, the following MIB fields have been added. These fields allow you to use SNMP to monitor more session table information for NP6 processors including drift for each NP6 processor.

```
FORTINET-FORTIGATE-MIB::fgNPUNumber.0 = INTEGER: 2
FORTINET-FORTIGATE-MIB::fgNPUName.0 = STRING: NP6
FORTINET-FORTIGATE-MIB::fgNPUDrvDriftSum.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUIIndex.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUIIndex.1 = INTEGER: 1
FORTINET-FORTIGATE-MIB::fgNPUSessionTblSize.0 = Gauge32: 33554432
FORTINET-FORTIGATE-MIB::fgNPUSessionTblSize.1 = Gauge32: 33554432
FORTINET-FORTIGATE-MIB::fgNPUSessionCount.0 = Gauge32: 0
FORTINET-FORTIGATE-MIB::fgNPUSessionCount.1 = Gauge32: 0
FORTINET-FORTIGATE-MIB::fgNPUDrvDrift.0 = INTEGER: 0
FORTINET-FORTIGATE-MIB::fgNPUDrvDrift.1 = INTEGER: 0
```

## Hardware acceleration (5.6.1)

New hardware acceleration features added to FortiOS 5.6.1.

### Optionally disable NP6 offloading of traffic passing between 10Gbps and 1Gbps interfaces (392436)

Due to NP6 internal packet buffer limitations, some offloaded packets received at a 10Gbps interface and destined for a 1Gbps interface can be dropped, reducing performance for TCP and IP tunnel traffic. If you experience this performance reduction, you can use the following command to disable offloading sessions passing from 10Gbps interfaces to 1Gbps interfaces:

```
config system npu
    set host-shortcut-mode host-shortcut
end
```

Select `host-shortcut` to stop offloading TCP and IP tunnel packets passing from 10Gbps interfaces to 1Gbps interfaces. TCP and IP tunnel packets passing from 1Gbps interfaces to 10Gbps interfaces are still offloaded as normal.

If `host-shortcut` is set to the default `bi-directional` setting, packets in both directions are offloaded.

## Hardware acceleration (5.6)

New hardware acceleration features added to FortiOS 5.6.

### Improved visibility of SPU and nTurbo hardware acceleration (389711)

All hardware acceleration hardware has been renamed Security Processing Units (SPUs). This includes NPx and CPx processors.

SPU and nTurbo data is now visible in a number of places on the GUI. For example, the Active Sessions column pop-up in the firewall policy list and the Sessions dashboard widget:

You can also add SPU filters to many FortiView pages.

### NP4Lite option to disable offloading ICMP traffic in IPsec tunnels (383939)

In some cases ICMP traffic in IPsec VPN tunnels may be dropped by the NP4Lite processor due to a bug with the NP4Lite firmware. You can use the following command to avoid this problem by preventing the NP4Lite processor from offloading ICMP sessions in IPsec VPN tunnels. This command is only available on FortiGate models with NP4Lite processors, such as the FortiGate/FortiWiFi-60D.

```
config system npu
    set process-icmp-by-host {disable | enable}
end
```

The option is disabled by default and all ICMP traffic in IPsec VPN tunnels is offloaded where possible. If you are noticing that ICMP packets in IPsec VPN tunnels are being dropped you can disable this option and have all ICMP traffic processed by the CPU and not offloaded to the NP4Lite.

### NP6 IPv4 invalid checksum anomaly checking (387675)

The following new options have been added to NP6 processors to check for IPv4 checksum errors in IPv4, TCP, UDP, and ICMP packets.

```
config system np6
    edit {np6_0 | np6_1 | ...}
        config fp-anomaly
            set ipv4-csum-err {drop | trap-to-host}
            set tcp-csum-err {drop | trap-to-host}
            set udp-csum-err {drop | trap-to-host}
            set icmp-csum-err {drop | trap-to-host}
        end
    end
```

You can use the new options to either drop packets with checksum errors (the default) or send them to the CPU for processing. Normally you would want to drop these packets.

As well, note that when configuring NP6 anomaly protection, the separate options `config fp-anomaly-v4` and `config fp-anomaly-v6` have been combined under `config fp-anomaly`.

### Stripping clear text padding and IPsec session ESP padding (416950)

In some situations, when clear text or ESP packets in IPsec sessions may have large amounts of layer 2 padding, the NP6 IPsec engine may not be able to process them and the session may be blocked.

If you notice dropped IPsec sessions, you could try using the following CLI options to cause the NP6 processor to strip clear text padding and ESP padding before sending the packets to the IPsec engine. With padding stripped, the session can be processed normally by the IPsec engine.

Use the following command to strip ESP padding:

```
config system npu
  set strip-esp-padding enable
  set strip-clear-text-padding enable
end
```

Stripping clear text and ESP padding are both disabled by default.

## High Availability (5.6.1)

New High Availability features added to FortiOS 5.6.1.

### HA cluster Uptime on HA Status dashboard widget (412089)

The HA Status dashboard widget now displays how long the cluster has been operating (Uptime) and the time since the last failover occurred (State Changed). You can hover over the State Changed time to see the event that caused the state change.

You can also click on the HA Status dashboard widget to configure HA settings or to get a listing of the most recent HA events recorded by the cluster.

HA Status	
Mode	Active-Passive
Group	External-HA-Cluster
Master	✓ External-Primary
Slave	✓ External-Backup
Uptime	29:22:51:05
State Changed	08:00:07:10

### FGSP with static (non-dialup) IPsec VPN tunnels and controlling IKE routing advertisement (402295)

Until FortiOS 5.6.1, the FortiGate Session Life Support Protocol (FGSP) only supported IPsec tunnel synchronization for dialup (or dynamic) IPsec VPN tunnels. FortiOS 5.6.1 now also supports IPsec tunnel synchronization for static IPsec VPN tunnels. No special FGSP or IPsec VPN configuration is required. You can configure static IPsec VPN tunnels normally and create a normal FGSP configuration.

An additional feature has been added to support some FGSP configurations that include IPsec VPNs. A new CLI option allows you to control whether IKE routes are synchronized to all units in the FGSP cluster.

```
config system cluster-sync
  edit 0
    set slave-add-ike-routes {enable | disable}
  end
```

Enable to synchronize IKE routes, disable if you do not need to synchronize IKE routes. Enabling routing synchronization is optional but doing so increases synchronization overhead and bandwidth usage. If you have problems with IPsec VPN tunnel synchronization you may want to enable synchronizing routes otherwise you could leave it disabled to improve performance and save bandwidth.

## VRRP support for synchronizing firewall VIPs and IP Pools (0397824)

FortiOS VRRP HA now supports failover of firewall VIPs and IP Pools when the status of a virtual router (VR) changes. This feature introduces a new proxy ARP setting to map VIP and IP Pool address ranges to each VR's Virtual MAC (VMAC). After failover, the IP Ranges added to the new primary VR will be routed to the new primary VR's VMAC.

Use the following command to add a proxy ARP address range and a single IP address to a VR added to a FortiGate's port5 interface. The address range and single IP address should match the address range or single IP for VIPs or IP Pools added to the port5 interface:

```
config system interface
edit port5
config vrrp
edit 1
config proxy-arp
edit 1
set ip 192.168.62.100-192.168.62.200
next
edit 2
set ip 192.168.62.225
end
```

## High Availability (5.6)

New High Availability features added to FortiOS 5.6.

### Multicast session failover (293751)

FGCP HA multicast session synchronization supports multicast session failover. To configure multicast session failover, use the following command to change the multicast TTL timer to a smaller value than the default. The recommended setting to support multicast session failover is 120 seconds (2 minutes). The default setting is 600 seconds (10 minutes).

```
config system ha
set multicast-ttl 120
end
```

The multicast TTL timer controls how long to keep synchronized multicast routes on the backup unit (so they are present on the backup unit when it becomes the new primary unit after a failover). If you set the multicast TTL lower the multicast routes on the backup unit are refreshed more often so are more likely to be accurate. Reducing this time causes route synchronization to happen more often and could affect performance.

### Performance improvement when shutting down or rebooting the primary unit (380279)

In previous versions of FortiOS, if you entered the `execute reboot` or `execute shutdown` command on the primary unit, a split brain configuration could develop for a few seconds while the primary unit was shutting down. This would happen because the heartbeat packets would stop being sent by the primary unit, while it was still able to forward traffic. When the heartbeat packets stop the backup unit becomes the primary unit. The result was a split brain configuration with two primary units both capable of forwarding traffic.

This wouldn't happen all the time, but when it did network traffic would be delayed until the primary unit shut down completely. To resolve this issue, in FortiOS 5.6 when you run the `execute reboot` or `execute shutdown` command on the primary unit, the primary unit first becomes the backup unit before shutting down

allowing the backup unit to become the new primary unit and avoiding the split brain scenario. This behavior only happens when you manually run the `execute reboot` or `execute shutdown` command from the primary unit.

### VRRP failover process change (390938)

In a FortiOS 5.6 VRRP configuration, when the master cannot reach its next hop router (vrdst) it sends packets to the configured backup router(s). These packets set the priority of the master to be lower than the backup router(s). So a backup router now becomes the new master and takes over processing traffic.

Use the `vrdst-priority` option to set the lower priority that the master sends to the backup routers. The following CLI syntax resets the master's priority to 10 if it can no longer connect to its next hop router.

```
config system interface
edit port10
config vrrp
set vrip 10.31.101.200
set priority 255
set vrdst 10.10.10.1
set vrdst-priority 10
end
```

### Display cluster up time and history (get system ha status command changes)(394745)

The `get system HA status` command now displays cluster uptime and history:

```
get system status
Version: FortiGate-5001D v5.6.0,build1413,170121 (interim)
...
Current HA mode: a-p, master
Cluster uptime: 3 days, 4 hours, 3 minutes, 46 seconds
...
```

### In-band HA management Interface (401378)

You can use the following command to add a management interface to an individual cluster unit interface that is also connected to a network and processing traffic. The in-band management interface is an alternative to the reserved HA management interface feature and does not require reserving an interface just for management access.

```
config system interface
edit port1
set management-ip 172.20.121.155/24
end
```

The management IP address is accessible from the network that the cluster interface is connected to. This setting is not synchronized so each cluster unit can have their own management IP addresses. You can add a management IP address to each cluster unit interface. You can use the `execute ha manage` command to connect to individual cluster units.

The `management-ip` can be on the same subnet as the interface you are adding it to but cannot be on the same subnet as other cluster unit interfaces.

### Up to four dedicated HA management interfaces supported (378127)

You can now add up to four dedicated HA management interfaces. Just like all FortiGate interfaces, these management interfaces must be on a different subnet from any other FortiGate interface. You can also configure

a separate default gateway for each interface.

Use the following command to add two dedicated HA management interfaces:

```
config system ha
  set ha-mgmt-status enable
  config ha-mgmt-interfaces
    edit 1
      set interface port4
      set gateway 10.10.10.1
    next
    edit 2
      set interface port5
      set gateway 4.5.6.7
  end
```

### FGSP support for automatic session sync after peer reboot (365851)

New options allow you to configure your FGSP cluster to resume sessions more smoothly after a failed FortiGate rejoins the cluster. In some cases when a failed FortiGate in the cluster comes back up it may begin processing sessions before the session table has been synchronized to it from the other FortiGate in the cluster. When this happens, the FortiGate may drop packets until the session synchronization is complete.

### Shutting down interfaces during session synchronization

This new feature allows you to shut some interfaces down on the failed FortiGate when it is starting up so that it will not accept packets until session synchronization is complete. Then the interfaces are brought up and traffic can flow. While the interfaces are down, the FortiGate that had not failed keeps processing traffic.

Use the following command to select the interfaces to shutdown while waiting for session synchronization to complete:

```
config system cluster-sync
  edit 1
    set down-intfs-before-sess-sync port1 port2
  end
```

### Heartbeat monitoring

If the FortiGate that was running fails before session synchronization is complete, the FortiGate that is restarting would not be able to complete session synchronization and would not turn on its shutdown interfaces. To prevent this from happening FGSP now includes heartbeat monitoring. Using heartbeat monitoring the FortiGate that is waiting for session synchronization to finish can detect that the other FortiGate is down and turn on its interfaces even if session synchronization is not complete. You can use the following command to change the heartbeat interval (hb-interval) and lost heartbeat threshold (hb-lost-threshold) to change heartbeat monitoring timing.

```
config system cluster-sync
  edit 1
    set hb-interval 2
    set hb-lost-threshold 3
  end
```

## NTP over Dedicated HA management interfaces (397889)

If you set up dedicated management interfaces on each cluster unit, if NTP is enabled, the primary unit contacts an NTP server using the dedicated management interface. System time is then synchronized to the backup units through the HA heartbeat.

Example CLI:

```
config system interface
  edit port5
    set ip 172.16.79.46 255.255.255.0
  end

config system ha
  set group-name FGT-HA
  set mode a-p
  set ha-mgmt-status enable
  config ha-mgmt-interfaces
    edit 1
      set interface port5
      set gateway 172.16.79.1
    end
  set ha-direct enable
end

config system ntp
  set ntpsync enable
  set syncinterval 5
end
```

## IPsec VPN (5.6.3)

New IPsec VPN features added to FortiOS 5.6.3.

### IPsec performance improvements for VM (439030)

In IPsec AES-GCM and AES-CBC-SHA mode, this feature leverages Intel AES-NI instructions to accelerate cipher and GCM operations, and uses Intel SSSE3 instructions to accelerate SHA1/SHA256 HMAC operations.

New entries to call Intel aesni directly:

- supported algorithms include: aesni, aesni-gcm, sha1/256/384/512-ssse3/avx/avx2
- some necessary additions, such as aes-gcm generic functions for non-aesni uses

This feature removes the old aes-gcm implementation using Linux Crypto API so that all the software crypto algorithms are under the Crypto\_ftnt umbrella.

Two new diagnose commands have been introduced in this feature:

```
diagnose vpn ipsec driver    (shows software crypto drivers in use)
diagnose vpn ipsec cpu      (shows crypto CPU distribution)
```

### Improved support for dynamic routing over dynamic IPsec interfaces (435152) (446498) (447569)

Solutions have been introduced to resolve the following issues:

- IPv6 RIP does not successfully exchange routes over ADVPN if the hub has 'set net-device disable'.
- BGP over an IPsec tunnel established by an IKE mode-cfg client connected to IKE mode-cfg server with 'set net-device disable' cannot establish.
- Multicast traffic does not flow over a 'set type dynamic' IPsec interface with 'set net-device disable'.

For 'set type dynamic' + 'set net-device disable' + 'set mode-cfg enable' + 'set add-route disable' then do `_not_` allocate a /30 (/126 for IPv6) as is done when 'set net-device enable', instead allocate a single IP address to the peer.

When the 'set type dynamic' tunnel negotiates, then add an IPsec peer route with the peer's allocated IP address pointing at the newly negotiated tunnel. Note this is an IPsec peer route not a regular route. A regular route is *not* added (unlike the case of 'set net-device enable').

'Config router static' / 'set device xxx' can now refer to a 'set type dynamic' IPsec interface. This allows the admin to define a static route covering the address range of the pool from which peer IP addresses will be allocated.

### BMRK IPsec UDP performance for AES256GCM drops after AES-NI checked in (452164)

This new feature fixes the aesni-cbc errors and precomputed the per-SA constant elements for aesni-gcm.

#### 1. aesni-cbc

When ECO 106922 was checked in, there was a known issue that the aesni-cbc driver wasn't working. The solution at that time was aesni plus generic cbc.

With this ECO, we fixed the errors in Intel's aesni-cbc driver so that we can fully leverage the aesni-cbc benefits. The aesni-cbc is faster than aesni plus generic cbc because:

- a. it can do cbc in one go with its 128-bits xmm registers.
- b. it can decrypt 4 blocks at the same time instead of one. It uses alternating AESDEC(Intel's aes instruction) on different blocks to speed up the calculations.

QA's tests show that with this, we can boost aes-cbc-sha1's throughput by 10+%.

## 2. AES fall-back function changed to Intel's x86\_64 assembly from C generic function

When fpu is not available, aesni can't be used and must fall back to a generic function. The assembly aes function should be slightly faster than the C generic one.

This would also slight boost aes throughput for those that don't have aesni but have a x86\_64 cpus.

## 3. aesni-gcm pre-computations

There are some elements in the aesni-gcm algo that maintain constant per-SA. This ECO moves these calculations to the prepare() function so that these calculations are only done once per-SA instead of per-packet.

QA's tests show that this helps to stabilize the 1500D aesni-gcm throughput and make it maintain above 1Gbps (packet size 1360).

## 4. Added counter reset function for diagnose commands:

```
diagnose vpn ipsec driver clear
diagnose vpn ipsec cpu clear
```

## IPsec dial-up interface sharing (379973)

This feature makes it possible to use a single interface for all instances that spawn via a given phase1. Instead of creating an interface per instance, all traffic will run over the single interface and any routes that need creating will be created on that single interface.

A new CLI option "net-device [enable|disable]" is added in the phase1-interface command sets. The default is "disable" so that the new feature kicks in for all the new configurations. An upgrade feature will add a "set net-device enable" for all the existing configurations so that they will keep the old behavior. Please see the CLI Syntax section below for more details.

Under the new single-interface scheme, instead of relying on routing to guide traffic to the specific instance as currently happens, all traffic will flow to the specific device and IPsec will need to take care of locating the correct instance for outbound traffic. For this purpose, another new CLI option "tunnel-search" is created. The option is only available when the above "net-device" option is "disable".

There are two options for "tunnel-search", corresponding to the two ways to select the tunnel for outbound traffic. One is "selectors", meaning selecting a peer using the IPSec selectors (proxy-ids). The other is "nexthop" where all the peers use the same default selectors (0/0) while using some routing protocols such as BGP, OSPF, RIPng, etc to resolve the routing. The default for "tunnel-search" is "selectors".

## Syntax

```
config vpn ipsec phase1-interface
  edit xxx
    set net-device [enable|disable] Enable to create a kernel device for every dialup instance
  next
end
config vpn ipsec phase1-interface
  edit xxx
    set net-device disable
    set tunnel-search [selectors|nexthop] Search for tunnel in selectors or using nexthops
```

```

    next
end

```

## IPsec VPN (5.6.1)

New IPsec VPN features added to FortiOS 5.6.1.

### Support for Brainpool curves specified in RFC 6954 for IKE (412795)

Added support for Brainpool curves specified in [RFC 6954](#) (originally RFC 5639) for IKE. Four new values are added for VPN phase1 and phase2 DH groups.

The allocated transform IDs are 27, 28, 29, 30:

- 27 - Brainpool 224-Bit Curve
- 28 - Brainpool 256-Bit Curve
- 29 - Brainpool 384-Bit Curve
- 30 - Brainpool 512-Bit Curve

### Syntax

```

config vpn ipsec phase1/phase1-interface
    edit <name>
        set dhgrp {1 | 2 | 5 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 27 | 28 | 29 | 30}
    next
end
config vpn ipsec phase2/phase2-interface
    edit <name>
        set dhgrp {1 | 2 | 5 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 27 | 28 | 29 | 30}
    next
end

```

### Removed "exchange-interface-ip" option from "vpn ipsec phase1" (411981)

The command `exchange-interface-ip` only works for interface-based IPsec VPN (`vpn ipsec phase1-interface`), and so it has been removed from policy-based IPsec VPN (`vpn ipsec phase1`).

### IKEv2 ancillary RADIUS group authentication (406497)

This feature provides for the IDi information to be extracted from the IKEv2 AUTH exchange and sent to a RADIUS server, along with a fixed password configurable via CLI, to perform an additional group authentication step prior to tunnel establishment. The RADIUS server may return framed-IP-address, framed-ip-netmask, and dns-server attributes, which are then applied to the tunnel.

It should be noted, unlike Xauth or EAP, this feature does not perform individual user authentication, but rather treats all users on the gateway as a single group, and authenticates that group with RADIUS using a fixed password. This feature also works with RADIUS accounting, including the `phase1 acct-verify` option.

### Syntax

```

config vpn ipsec phase1-interface
    edit <name>
        set mode-cfg enable
        set type dynamic
        set ike-version 2
    end
end

```

```

    set group-authentication {enable | disable}
    set group-authentication-secret <password>
  next
end

```

## IPsec mode-cfg can assign IPs from firewall address and sharing IP pools (393331)

This feature adds the ability for users to configure assign-IPs from firewall addresses/groups.

Previously, different policies accessing the same network needed to ensure that non-overlapping IP-ranges were assigned to policies to avoid the same IP address being assigned to multiple clients. With this feature, the address `name` is used to identify an IP pool and different policies can refer to the same IP pool to check for available IPs, thus simplifying the task of avoiding IP conflicts.

### Syntax

```

config vpn ipsec phase1-interface
  edit <name>
    set mode-cfg enable
    set type dynamic
    set assign-ip-from {range | dhcp | name}
    set ipv4-name <name>
    set ipv6-name <name>
  next
end

```

## Improve interface-based dynamic IPsec up/down time (379937)

This feature makes it possible to use a single interface for all instances that spawn via a given phase1. Instead of creating an interface per instance, all traffic will run over the single interface and any routes that need creating will be created on that single interface.

A new CLI option `net-device` is added in the `phase1-interface` command sets. The default is `disable` so that the new feature kicks in for all the new configurations. An upgrade feature will add a `set net-device enable` for all the existing configurations so that they will keep the old behavior.

Under the new single-interface scheme, instead of relying on routing to guide traffic to the specific instance, all traffic will flow to the specific device and IPsec will need to take care of locating the correct instance for outbound traffic. For this purpose, another new CLI option `tunnel-search` is created. The option is only available when the above `net-device` option is set to `disable`.

There are two options for `tunnel-search`, corresponding to the two ways to select the tunnel for outbound traffic. One is `selectors`, meaning selecting a peer using the IPsec selectors (proxy-ids). The other is `nexthop` where all the peers use the same default selectors (0/0) while using some routing protocols such as BGP, OSPF, RIPng, etc. to resolve the routing. The default for `tunnel-search` is `selectors`.

### Syntax

```

config vpn ipsec phase1-interface
  edit <name>
    set net-device {enable | disable}
    set tunnel-search {selectors | nexthop}
  next
end

```

### Hide psksecret option when peertype is dialup (415480)

In aggressive mode and IKEv2, when peertype is dialup, pre-shared key is per-user based. There is no need to configure the psksecret in the phase1 setup. Previously, if left unconfigured, CLI would output psksecret error and fail to create the phase1 profile.

To prevent psksecret length check running on the configuration end, the psksecret option will be hidden. Prior to Mantis 397712, the length check passed because it was incorrectly checking the length of encrypted password which is always 204 length long.

Peertype dialup option removed for main mode.

### New enforce-ipsec option added to L2TP config (423988)

A new `enforce-ipsec` option is added in L2TP configuration to force the FortiGate L2TP server to accept only IPsec encrypted connections.

#### Syntax

```
config vpn l2tp
    set eip 50.0.0.100
    set sip 50.0.0.1
    set status enable
    set enforce-ipsec-interface {disable | enable}    (default = disable)
    set usrgrp <group_name>
end
```

### IPsec VPN Wizard improvements (368069)

Previously, when using wan-load-balance (WLB) feature, and when configuring an IPsec tunnel with the wizard, the setting 'incoming interface' list does not contain the wan-load-balance nor the wan2 interface. Disabling the WLB permits the configuration.

The solution in 5.6.1 is as follows:

- (368069) The IPsec VPN wizard now allows users to select members of virtual-wan-link (VWL) as IPsec phase1-interface. Before saving, if the phase1 interface is a VWL member, then the Wizard automatically sets the virtual-wan-link as the destination interface in the L2TP policy.
- (246552) List VPN tunnels for VWL members if VWL is set as the destination interface in policy-based IPsec VPN.

### IPsec manual key support removed from GUI (436041)

The majority of customers are not using policy-based IPsec today, and beyond that, very few are using manual key VPN. As a result, the IPsec manual key feature is removed from the GUI; the feature store option is removed as well.

### Added GUI support for local-gw when configuring custom IPsec tunnels (423786)

Previously, the `local-gw` option was not available on the GUI when configuring a custom IPsec tunnel. This feature adds the `local-gw` setting to the IPsec VPN Edit dialog. The user is able to choose the primary or secondary IP address from the currently selected interface, or specify an ip address manually. Both `local-gw` and `local-gw6` are supported.

### Moved the dn-format CLI option from phase1 config to vdom settings (435542)

Previous fix for `dn-format` didn't take into account that, at the time `isakmp_set_peer_identifier` is used, we don't have a connection and haven't matched our gateway yet, so we can't use that to determine the `dn-format` configuration setting.

The solution was to move the `dn-format` CLI option from `phase1 config` to `vdom settings`. It is renamed to `ike-dn-format`.

### FGT IKE incorrect NAT detection causes ADVPN hub behind VIP to not generate shortcuts (416786)

When ADVPN NAT support was added, only spokes behind NAT was considered. No thought was given to a hub behind a VIP or the problems that occurred due to the way that FortiOS clients behind NAT enable NAT-T even when it is not required.

The solution in 5.6.1 is as follows:

- Moved shortcut determination out of the kernel and up to IKE. The shortcut message now contains the ID of both tunnels so that IKE can check the NAT condition of both.
- Added IKE debug to cover sending the initial shortcut query. The lack of this previously meant it could be awkward to determine if the offer had been converted into a query correctly.
- Added "nat:" output in `diag vpn ike gateway list` output to indicate whether this device or the peer is behind NAT.
- Tweaked the `diag vpn tunnel list` output so that the auto-discovery information now includes symbolic as well as numeric values, which makes it easier to see what type of auto-discovery was enabled.

## IPsec VPN (5.6)

New IPsec VPN features added to FortiOS 5.6.

### Improvement to stats crypto command output (403995)

The CLI command `get vpn ipsec stats crypto` now has a better format for the information it shows in differentiating between NP6 lite and SOC3 (CP). To further avoid confusion, all engine's encryption (encrypted/decrypted) and integrity (generated/validated) information is shown under the same heading, not separate headings.

### Improved certificate key size control commands (397883)

Proxy will choose the same SSL key size as the HTTPS server. If the key size from the server is 512, the proxy will choose 1024. If the key size is bigger than 1024, the proxy will choose 2048.

As a result, the `firewall ssl-ssh-profile` commands `certname-rsa`, `certname-dsa`, and `certname-ecdsa` have been replaced with more specific key size control commands under `vpn certificate` setting.

#### CLI syntax

```
config vpn certificate setting
  set certname-rsa1024 <name>
  set certname-rsa2048 <name>
  set certname-dsa1024 <name>
```

```
set certname-dsa2048 <name>
set certname-ecdsa256 <name>
set certname-ecdsa384 <name>
end
```

### Support bit-based keys in IKE (397712)

As per FIPS-CC required standards, as well as [RFC 4306](#), IKE supports pre-shared secrets to be entered as both ASCII string values and as hexadecimal encoded values. This feature parses hex encoded input (indicated by the leading characters **0x**) and converts the input into binary data for storage.

With this change, the `psksecret` and `psksecret-remote` entries under the IPsec VPN CLI command `config vpn ipsec phase1-interface` have been amended to differentiate user input as either ASCII string or hex encoded values.

### IKEv2 asymmetric authentication (393073)

Support added for IKEv2 asymmetric authentication, allowing both sides of an authentication exchange to use different authentication methods, for example the initiator may be using a shared key, while the responder may have a public signature key and certificate.

A new command, `authmethod-remote`, has been added to `config vpn ipsec phase1-interface`.

For more detailed information on authentication of the IKE SA, see [RFC 5996 - Internet Key Exchange Protocol Version 2 \(IKEv2\)](#).

### Allow mode-cfg with childless IKEv2 (391567)

An issue that prevented `childless-ike` from being enabled at the same time as `mode-cfg` has been resolved. Both options can now be enabled at once under `config vpn ipsec phase1-interface`.

### IKEv2 Digital Signature Authentication support (389001)

FortiOS supports the use of Digital Signature authentication, which changes the format of the Authentication Data payload in order to support different signature methods.

Instead of just containing a raw signature value calculated as defined in the original IKE RFCs, the Auth Data now includes an ASN.1 formatted object that provides details on how the signature was calculated, such as the signature type, hash algorithm, and signature padding method.

For more detailed information on IKEv2 Digital Signature authentication, see [RFC 7427 - Signature Authentication in the Internet Key Exchange Version 2 \(IKEv2\)](#).

### Passive static IPsec VPN (387913)

New commands have been added to `config vpn ipsec phase1-interface` to prevent initiating VPN connection. Static IPsec VPNs can be configured in tunnel mode, without initiating tunnel negotiation or rekey.

To allow a finer configuration of the tunnel, the `rekey` option is removed from `config system global` and added to `config vpn ipsec phase1-interface`.

### CLI syntax

```
config vpn ipsec phase1-interface
edit <example>
```

```
set rekey {enable | disable}
set passive-mode {enable | disable}
set passive-tunnel-interface {enable | disable}
end
```

## Phase 2 wizard simplified (387725)

Previously, for a site-to-site VPN, phase 2 selectors had their static routes created in the IPsec VPN wizard by adding IP addresses in string format. Now, since addresses and address groups are already created for these addresses, the address group can be used in the route directly. This means that the route can be modified simply by modifying the address/groups that were created when the VPN was initially created.

With this change, the VPN wizard will create less objects internally, and reduce complexity.

In addition, a blackhole route will be created by default with a higher distance-weight set than the default route. This is to prevent traffic from flowing out of another route if the VPN interface goes down. In these instances, the traffic will instead be silently discarded.

## Unique IKE ID enforcement (383296)

All IPsec VPN peers now connect with unique IKE identifiers. To implement this, a new `phase1` CLI command has been added (`enforce-unique-id`) which, when enabled, requires all IPsec VPN clients to use a unique identifier when connecting.

### CLI syntax

```
config vpn ipsec phase1
edit <name>
set enforce-unique-id {keep-new | keep-old | disable} Default is disable.
next
end
```

Use `keep-new` to replace the old connection if an ID collision is detected on the gateway.

Use `keep-old` to reject the new connection if an ID collision is detected.

## FortiView VPN tunnel map feature (382767)

A geospatial map has been added to FortiView to help visualize IPsec and SSL VPN connections to a FortiGate using Google Maps. Adds geographical-IP API service for resolving spatial locations from IP addresses.

This feature can be found under **FortiView > VPN**.

## Childless IKEv2 initiation (381650)

As documented in [RFC 6023](#), when both sides support the feature, no child IPsec SA is brought up during the initial AUTH of the IKEv2 negotiation. Support for this mode is not actually negotiated, but the responder indicates support for it by including a `CHILDLESS_IKEV2_SUPPORTED` Notify in the initial `SA_INIT` reply. The initiator is then free to send its AUTH without any SA or TS payloads if it also supports this extension.

### CLI syntax

```
config vpn ipsec phase1-interface
edit ike
set ike-version 2
set childless-ike enable
next
end
```

Due to the way configuration payloads (IKEV2\_PAYLOAD\_CONFIG) are handled in the current code base, mode-cfg and childless-ike aren't allowed to be enabled at the same time. Processing config payloads for mode-cfg requires a child ph2handle to be created, but with childless-ike we completely avoid creating the child ph2 in the first place which makes the two features incompatible. It may be possible to support both in the future, but a deeper rework of the config payload handling is required.

### Allow peertype dialup for IKEv2 pre-shared key dynamic phase1 (378714)

Restored `peertype dialup` that was removed in a previous build (when IKEv2 PSK gateway re-validation was not yet supported).

If `peertype` is `dialup`, IKEv2 AUTH verify uses user password in the user group "usrgrp" of phase1. The "psksecret" in phase1 is ignored.

#### CLI syntax

```
config vpn ipsec phase1-interface
  edit "name"
    set type dynamic
    set interface "wan1"
    set ike-version 2
    set peertype dialup
    set usrgrp "local-group"
  next
end
```

### IPsec default phase1/phase1-interface peertype changed from 'any' to 'peer' (376340)

Previously, when `authmethod` was changed to `signature`, `peertype` automatically changed to `peer` and required a peer to be set. This change was done to try to provide a more secure initial configuration, while allowing the admin to set `peertype` back to `any` if that's what they really wanted. The default value was kept at `any` in the CLI. However, this caused problems with copy/pasting configurations and with FMG because if `peertype any` wasn't explicitly provided, the CLI was switched to `peertype peer`.

This patch changes the default `peertype` to `peer` now; `peertype any` is considered non-default and will be printed out on any config listing. Upgrade code has been written to ensure that any older build that was implicitly using `set peertype any` has this setting preserved.

### IPsec GUI bug fixes (374326)

Accept type "Any peer ID" is available when creating IPsec tunnel with `authmethod`, pre-shared key, `ikev1` main mode/aggressive mode, and `ikev2`.

### Support for IKEv2 Message Fragmentation (371241)

Added support for IKEv2 Message Fragmentation, as described in [RFC 7383](#).

Previously, when sending and IKE packets with IKEv1, the whole packet is sent once, and it is only fragmented if there is a retransmission. With IKEv2, because [RFC 7383](#) requires each fragment to be individually encrypted and authenticated, we would have to keep a copy of the unencrypted payloads around for each outgoing packet, in case the original single packet was never answered and we wanted to retry with fragments. So with this

implementation, if the IKE payloads are greater than a configured threshold, the IKE packets are preemptively fragmented and encrypted.

**CLI syntax**

```
config vpn ipsec phase1-interface
  edit ike
    set ike-version 2
    set fragmentation [enable|disable]
    set fragmentation-mtu [500-16000]
  next
end
```

**IPsec monitoring pages now based on phase 1 proposals not phase 2 (304246)**

The IPsec monitor, found under **Monitor > IPsec Monitor**, was in some instances showing random uptimes even if the tunnel was in fact down.

Tunnels are considered as "up" if at least one phase 2 selector is active. To avoid confusion, when a tunnel is down, **IPsec Monitor** will keep the **Phase 2 Selectors** column, but hide it by default and be replaced with **Phase 1** status column.

## IPv6 (5.6.3)

New IPv6 features added to FortiOS 5.6.3.

### IPv6 RADIUS support (402437, 439773)

Added support for IPv6 RADIUS authentication. When configuring the FortiGate interface and the RADIUS server (under `config system interface` and `config user radius` respectively), the server IP address can be set as IPv6.

### Added support for IPv6 Fortisandbox (424290) (447153)

FortiOS can now communicate with a FortiSandbox if the FortiSandbox has an IPv6 IP address.

### IPv6 captive portal support (435435)

Captive portal now supports IPv6 addresses; works with remote RADIUS authentication and WiFi interfaces.

## IPv6 (5.6)

New IPv6 features added to FortiOS 5.6.

### FortiGate can reply to an anycast probe from the interface's unicast address (308872)

A new setting has been added within the CLI that can enable the FortiGate to reply to an anycast probe from the FortiGate's unicast IP address.

```
config system global
  set ipv6-allow-anycast-probe [enable|disable]
end
```

**Enable:** Enable probing of IPv6 address space through Anycast, by responding from the unicast IP address

**Disable:** Disable probing of IPv6 address space through Anycast

### Secure Neighbor Discovery (355946)

Additional settings have been added to the configuration for interfaces with IPv6 so that they comply more closely to the parameters of RFC 3971

The context of the new settings is

```
config system interface
  edit <interface>
  config ipv6
```

The new options with IPv6 are:

#### **ndmode**

Neighbor discovery mode

```
set ndmode [basic | SEND]
```

**Basic:** Does not support SEND.

**SEND**-compatible: Supports SEND.

#### **nd-cert**

Neighbor discovery certificate

```
set nd-cert <string of Name of certificate to be used>
```

Example string: "Fortinet\_Factory local"

#### **n-security-level**

Neighbor discovery security level

```
set nd-security-level <integer>
```

- Integer values from 0 - 7
- 0 = least secure
- 7 = most secure
- default = 0

#### **nd-timestamp-delta -**

Neighbor discovery timestamp delta value

```
set nd-timestamp-delta <integer of time in seconds>
```

- Range: 1 - 3600 sec
- default = 300

#### **nd-timestamp-fuzz**

Neighbor discovery timestamp fuzz factor

```
set nd-timestamp-fuzz <integer of time in seconds>
```

- Range: 1 - 60 sec
- default = 1

### **Additional related technical information**

#### **Kerenl**

- Redirects ICMPv6 packets to user space if they require SEND options verification or build.

#### **Radvd**

- Verifies NS/RS SEND options including CGA, RSA, Timestamp, NONCE, etc. Daemon also creates neighbor cache for future timestamp checking, any entry gets flushed in 4 hours.
- Helps kernel build NA/RA SEND options including CGA, RSA, Timestamp, NONCE, etc. CGA parameters are kept in cache for each interface. CGA modifier is kept in CMDB.

**Diagnose command for radvd**

```
diag test application radvd
```

- Shows statistics
- Toggles message dump

**Add multicast-PMTU to allow FGT to send ICMPv6 Too Big Message (373396)**

New multicast-PMTU feature added to better comply with RFC 4443.

Normally, a “Packet Too Big” icmp6 message is sent by a routing device in response to a packet that it cannot forward because the packet is larger than the MTU of the outgoing link. For security reasons, these message may be disabled because attackers can use the information about a victim's ip address as the source address to do IP address spoofing.

In FortiOS's implementation of this function, a setting in the CLI, has been added to make this behavior optional on the FortiGate.

The syntax for the option is:

```
config router multicast6
  set multicast-PMTU [enable|disable]
end
```

## Logging and Reporting (5.6.3)

New logging and reporting features added to FortiOS 5.6.3.

### Improve FortiAnalyzer storage usage on Log Settings page (409658)

This feature improves FortiAnalyzer storage usage information in log settings to include more detailed per-ADOM information as follows:

- (1) FAZ ADOM (Name)  
Size / Used
- (2) Indexed Logs  
Used / Available  
Data Policy Days Configured / Actual
- (3) Compressed Logs  
Used / Available  
Data Policy Days Configured / Actual

### Range change for maximum log age (440633)

The value range for "maximum-log-age" under "config log disk setting" has been limited to 0-3650.

### New connect and disconnect event logs for FSSO server status change (446263)

Connect and disconnect event logs for FSSO server status changes have been added according to the following:

- When FSSO server status changes from disconnected to connected, record one connected event.
- When FSSO server status changes from connected to disconnected, record one disconnected event and send one FSSO server disconnected alert email when set.

These logs must be enabled in the CLI.

#### Syntax

```
config alertemail setting
  set FSSO-disconnect-logs
```

### Security Fabric audit result logging to FortiGuard (452588)

The CLI now includes an option for the user to enable (by default) or disable FortiGuard security fabric audit result submission.

If enabled, every time a user runs the Security Fabric audit test on the FortiGate, the audit result will be sent to FortiGuard. When disabled, no audit data is sent to FortiGuard.

Security Audit categories have been reorganized and renamed to reflect the categories as they are in the security audit matrix.

#### Syntax

```
config system global
  set fortiguard-audit-result-submission [enable | disable]
end
```

### Config log disk uploadtime units change (400999)

Instructions for upload time under "config log disk setting" has been clarified by adding the phrase 'daily upload' and mentioning that this is the Hour. The help text also now includes the acceptable range for more clarity.

### Log field extension policy-name and meta-field (455441)

An option to include the policy name field has been added to traffic logs (log-policy-name). Likewise, an option to add a meta-field tag to all logs has also been added (custom-field and custom-log-fields; see below). This meta-field could be used for identifying the fortigate sending the logs, for example.

These options can only be enabled in the CLI.

#### Syntax

```
config log setting
    set log-policy-name [enable | disable]
end
config log custom-field
    edit "aaa"
        set name "fieldda"
        set value "111"
    next
end
config log setting
    set custom-log-fields "aaa"
end
```

### Rename logtime to eventtime (454445)

The "logtime" field in logs has been renamed to "eventtime" to avoid confusion. The logtime is the timestamp that miglogd receives the message.

## Logging and Reporting (5.6.1)

New logging and reporting features added to FortiOS 5.6.1.

### Usability Updates to Reports Page (383684)

The **Reports** page has been updated in 5.6.1, to include both FortiCloud and Local Reports in a single location. Configuring of report schedules is also available on this page. The page will display whichever format is enabled, or allow switching between both if both Local and FortiCloud are in use.

### Interface Categories (srcintfrole, etc) added to log data (434188)

In 5.6, logs and FortiView both sort log traffic into two interface categories: "Traffic from LAN/DMZ", and "Traffic from WAN." For greater compatibility and troubleshooting of FortiAnalyzer and FortiCloud setups, interface category fields that expose this information have been added to general log data in 5.6.1: srcintfrole and dstintfrole for better backend control and monitoring.

## Logging and Reporting (5.6)

New logging and reporting features added to FortiOS 5.6.

### All string values in log messages are enclosed in double quotes (399871)

In previous versions, some string log fields have double quotes and some do not. FortiOS 5.6 adds double-quotes to all string fields in all log messages.

Some example log messages:

```
date=2017-01-27 time=10:46:26 logid="0001000014" type="traffic"
subtype="local" level="notice" vd="vd1" srcip=172.16.200.1 srcport=17856
srcintf=unknown-0 dstip=192.168.100.206 dstport=53 dstintf="port1"
sessionid=1461 proto=17 action="accept" policyid=0 dstcountry="Reserved"
srccountry="Reserved" trandisp="noop" service="DNS" app="DNS" duration=180
sentbyte=92 rcvdbyte=0 sentpkt=1 rcvdpkt=0 appcat="unscanned"

date=2017-01-27 time=10:36:34 logid="0107045071" type="event"
subtype="endpoint" level="notice" vd="vd1" logdesc="FortiClient Vulnerability
Scan" scantime=1467851105 fctuid="A8BA0B12DA694E47BA4ADF24F8358E2F"
user="test-user" srcip=192.168.25.26 srcname="test-pc"
srcmac="01:02:03:04:05:06" devtype="Windows PC" vulnid=25894
vulnname="Security Vulnerability CVE-2016-0636 in Oracle JDK"
vulncat="Applications" severity="critical" cveid="CVE-2016-0636"
vendorurl="http://www.oracle.com/technetwork/topics/security/alert-cve-2016-
0636-2949497.html" msg="Endpoint Vulnerability Scan."
```

### Client and server certificates included in Application control log messages (406203)

When SSL/TLS traffic triggers an application control signature, the application control log messages now include information about the signatures used by the session. This includes the client certificate issuer, the name in the server certificate, and the server certificate issuer.

### DNS Logging (401757)

FortiOS logging now includes the Detailed DNS log message type. DNS events were previously recorded as event logs. In FortiOS 5.6 DNS log messages are a new category that also includes more DNS log messages to provide additional detail about DNS activity through the FortiGate. You can enable DNS logging from the CLI using the following command (shown in this example for memory logging):

```
config log memory filter
    set dns enable
end
```

DNS log messages include details of each DNS query and response. DNS log messages are recorded for all DNS traffic though the FortiGate and originated by the FortiGate.

The detailed DNS logs can be used for low-impact security investigation. Most network activity involves DNS activity of some kinds. Analyzing DNS logs can provide a lot of details about the activity on your network without using flow or proxy-based resource intensive techniques.

### Added Policy Comment logging option (387865)

As an alternative to custom log fields, the functionality has been added to log a policy's comment field in all traffic log files that use that policy, in order to sort/isolate logs effectively with larger deployments and VDOMs. The feature is disabled by default.

```
config log setting
    set log policy comment [enable/disable]
```

### FortiAnalyzer encryption option name change (399191)

For clarity, and because the default options for `config log fortianalyzer setting` have now changed, the option `default` has now been changed to `high-medium` in the following CLI commands:

```
config log fortianalyzer setting
    set enc-algorithm [high/high-medium/low]
config log fortianalyzer override-setting
    set enc-algorithm [high/high-medium/low]
config log fortiguard setting
    set enc-algorithm [high/high-medium/low]
config log fortiguard override-setting
    set enc-algorithm [high/high-medium/low]
```

## Maximum values changes

Maximum values changes in FortiOS 5.6.3:

- Merged FGT 90E/91E into trunk (386658).
- Merged FGT 3960E/3980E into 5.6 and trunk (435854).

Maximum values changes in FortiOS 5.6.1:

- The maximum number of SSIDs (CLI command `config wireless-controller vap`) for FortiGate models 600C, 600D, 800C, 800D, and 900D increased from 356 to 512 (414202).
- The maximum number DLP sensors (CLI command `config dlp sensor / config filter`) for models 1000C, 1000D, 1200D, 1500D, 1500DT, 3240C, and 3600C decreased from 10,000 to 3,000. (371270)
- The maximum number DLP sensors (CLI command `config dlp sensor / config filter`) for models 3000D, 3100D, 3200D, 3700D, 3700DX, 3800D, 3810D, 3815D, 5001C, and 5001D decreased from 50,000 to 4,000. (371270)

Maximum values changes in FortiOS 5.6:

- The maximum number of wireless controller QoS Profiles is per VDOM (388070).

## Modem (5.6.1)

New modem features added to FortiOS 5.6.1.

### New modem features (422266)

New FortiOS 5.6.1 modem features include:

- The ability to edit wireless profiles stored on EM7x modems from FortiOS.
- GPS support.
- MIB for internal LTE modems.
- Syslog messages for internal LTE modems.
- More status information displayed by the `diagnose sys lte-modem` command
- New modem-related MIB entities.

### `config system lte-modem` command changes

The `mode`, `interface`, and `holddown-timer` options of the `config system lte-modem` command have been removed. These options are no longer needed. Instead, use SD-WAN for redundant interfaces.

The `config system lte-modem` command includes the following options

`status` Enable/disable USB LTE/WIMAX device.

`extra-init` Extra initialization string to USB LTE/WIMAX device.

`manual-handover` Enable/Disable manual handover from 3G to LTE network. If enabled, the FortiGate switches the modem firmware to LTE mode if the modem itself fails to do so after 5 loops.

`force-wireless-profile` Force the modem to use the configured wireless profile index (1 - 16), 0 if don't force. If your FortiGate includes an LTE modem or if an LTE modem is connected to it you can use the `execute`

`lte-modem` command to list the LTE modem profiles. Use this command to select one of these wireless profiles.

Wireless profiles contain detailed LTE modem data session settings. In each modem, a maximum of 16 wireless profiles can be stored, any data connections are initiated using settings from one of the stored wireless profiles. To make a data connection, at least one profile must be defined. Here is a sample wireless profile table stored in one of the internal modems:

```
FG30EN3U15000025 # execute lte-modem wireless-profile list
```

ID	Type	Name	APN	PDP_Type	Authen	Username
*1	0	profile1	vzwims	3	0	
2	0	profile2	vzwadmin	3	0	
3	0	profile3	VZWINTERNET	3	0	
4	0	profile4	vzwapp	3	0	
5	0	profile5	vzw800	3	0	
9	0	profile9	vzwims	2	0	
10	0	profile10	vzwadmin	0	0	
11	0	profile11	VZWINTERNET	0	0	
12	0	profile12	vzwapp	3	0	
13	0	profile13		0	0	

Profile Type:

```
0 ==> QMI_WDS_PROFILE_TYPE_3GPP
1 ==> QMI_WDS_PROFILE_TYPE_3GPP2
* ==> Default 3GPP Profile, # ==> Default 3GPP2 Profile
```

Profile PDP Type:

```
0 ==> QMI_WDS_PDP_TYPE_IPV4
1 ==> QMI_WDS_PDP_TYPE_PPP
2 ==> QMI_WDS_PDP_TYPE_IPV6
3 ==> QMI_WDS_PDP_TYPE_IPV4_OR_IPV6
```

Authentication:

```
0 ==> QMI_WDS_AUTHENTICATION_NONE
1 ==> QMI_WDS_AUTHENTICATION_PAP
2 ==> QMI_WDS_AUTHENTICATION_CHAP
3 ==> QMI_WDS_AUTHENTICATION_PAP|QMI_WDS_AUTHENTICATION_CHAP
```

`authtype` Authentication type for PDP-IP packet data calls.

`apn` Log in APN string for PDP-IP packet data calls.

`modem-port` Modem port index (0 - 20).

`network-type` Set wireless network.

`auto-connect` Enable/disable Modem auto connect.

`gpsd-enabled` Enable/disable GPS daemon.

`data-usage-tracking` Enable/disable data usage tracking.

`gps-port` Modem port index (0 - 20). Specify the index for GPS port, by default it is set to 255 which means to use the system default.

### execute lte-modem command changes

The following options are available for the `execute lte-modem` command:

`cold-reboot` Cold reboot LTE Modem, which means power off the internal modem and power it on again after 1 second.

`get-modem-firmware` get-modem-firmware

`get-pri-firmware` get-pri-firmware

`power-off` Power off LTE Modem.

`power-on` Power on LTE Modem.

`purge-billing-data` Purge all existing LTE Modem billing data.

`reboot` Warm reboot LTE Modem.

`set-operation-mode` Set LTE Modem operation mode to online or offline.

`wireless-profile` wireless-profile

`cold-reboot`, `power-off`, `power-on`, `set-operation-mode`, and `wireless-profile` are new in FortiOS 5.6.1.

### New execute lte-modem wireless-profile command

The following options are available for the `execute lte-modem wireless-profile` command:

`create` Create a wireless profile. You use the `create` command to create an LTE modem profile by providing a name and supplying settings for the profile. The command syntax is:

```
execute lte-modem wireless-profile create <name> <type> <pdp-type> <apn-name> <auth-type>
    [<user> <password>]
```

`<name>` Wireless profile name of 1 to 16 characters.

`<type>` Wireless profile type:

- 0 for 3GPP profiles.
- 1 for 3GPP2 profiles.

`<pdp-type>` Wireless profile PDP type.

- 0 for IPv4
- 1 for PPP
- 2 for IPv6
- 3 for IPv4v6

`<apn-name>` Wireless profile APN name, 0 to 32 characters.

`<auth-type>` Wireless profile authentication type.

- 0 for no authentication.
- 1 for PAP
- 2 for CHAP
- 3 for PAP and CHAP

[<user> <password>] Wireless profile user name and password (1 to 32 characters each). Not required if <auth-type> is 0.

For example, use the following command to create an LTE modem 3GPP IPv4 profile named myprofile6. This profile uses the APN profile named p6apn that uses PAP and CHAP authentication.

```
execute lte-modem wireless-profile create myprofile 0 0 myapn 3 myname mypasswd
```

**delete <profile-number>** Delete a wireless profile from the Modem. Specify profile ID of the profile to delete.

**list** List all the wireless profiles stored in the Modem. If the modem is busy the list may not display. If this happens just repeat the command. It may take a few attempts.

**modify** Modify a wireless profile using the same settings as the create command except the first option is the profile ID. You can find the profile ID for each profile by listing the profiles using the `execute lte-modem wireless-profile list` command. For example, to modify the profile created above to change it to an IPv4v6 profile, change the APN profile to yourapn, and set the authentication type to PAP enter the following command (assuming the profile ID is 6):

```
execute lte-modem wireless-profile modify 6 myprofile 0 3 yourapn 1 myname mypasswd
```

**test** Test wireless profiles.

### Static mode for wwan interface removed (440865)

When configuring the wireless modem wwan interface from the CLI the `mode` can only be set to DHCP. Static addressing for the wwan interface is not supported so the `static` option has been removed.

## Networking (5.6.3)

New networking features added to FortiOS 5.6.3.

### Static Route GUI page updates (268344)

Updates have been made to the **New Static Route/Edit Static Route** page (under **Network > Static Routes**) so as to avoid the device interface being selected first before the gateway. The admin can now specify the gateway first, then the device interface will populate automatically based on the gateway. In addition, if the gateway is not in the same subnet as the selected interface, a warning message will appear.

### Advanced Routing GUI updates (413433, 445075)

Fixed an issue where an interface was not able to be deleted in the GUI under **Network > Multicast > Multicast Routing**.

### VXLAN interfaces can be attached to loopback interfaces (436773)

Support has been added for VXLAN unicast devices to be "binded" to the loopback interface as its underlying interface:

- The IP address of the loopback interface would be taken as the source IP for its outgoing VXLAN packets, so that the peer knows where to reply.
- Among parameters passing to kernel, the ifindex of the loopback interface is not actually passed down to kernel, so that the kernel can freely choose the physical outgoing interface.

VXLAN traffic can be routed across multiple physical links, providing resistance to single points of failure.

### New option to configure DHCP renew time (440923)

Support has been added to allow you to set a minimum DHCP renew time in seconds (under `config system interface`). Note that this entry is only available when `mode` is set to `dhcp`.

#### Syntax

```
config system interface
  edit {name}
    set dhcp-renew-time <seconds>
  next
end
```

Set the DHCP renew time range between 300-604800 (or five minutes to seven days). You can use the renew time provided by the server by setting this entry to 0.

### Show/add IPv6 address for CLI "get" under interface and CLI "fnsysctl/sysctl ifconfig interface\_id" (442988, 230480)

Client IPv6 DHCP addresses were only available to view in the CLI by using `diagnose ipv6 address list`, but are also now available by entering `get` in the interface (under `config system interface`).

Similarly, static IPv6 addresses were available to view under `diagnose ipv6 address list` and by entering `get` under the interface, but are also now available by entering `fnsysctl/sysctl ifconfig interface_id`.

## DHCP Option 82 on Fortigate DHCP relay - RFC3046 (451456)

Support has been added to enable or disable DHCP relay option 82 (under config system interface), as referenced in [RFC3046](#): "Overall adding of the DHCP relay agent option SHOULD be configurable, and SHOULD be disabled by default".

### Syntax

```
config system interface
  edit {name}
    set dhcp-relay-agent-option {enable | disable}
  next
end
```

## Networking (5.6.1)

New networking features added to FortiOS 5.6.1.

### IPv6 Router Advertisement options for DNS enhanced with recursive DNS server option (399406)

This feature is based on [RFC 6106](#) and it adds the ability to obtain DNS search list options from upstream DHCPv6 servers and the ability to send them out through either Router Advertisement or FortiGate's DHCP server.

FortiOS 5.6 supported the following:

To get the information from the upstream ISP server:

```
config system interface
  edit wan1
    config ipv6
      set dhcp6-prefix-delegation enable
    next
  next
end
```

To use Routing Advertisement to send the DNS search list:

```
config system interface
  edit port 1
    config IPv6
      set ip6-address 2001:10::/64
      set ip6-mode static
      set ip6-send-adv enable
      config ip6-delegated-prefix-list
      edit 1
        set upstream-interface WAN
        set subnet 0:0:0:11::/64
        set autonomous-flag enable
        set onlink-flag enable
      next
    next
  end
end
```

To use DHCPv6 server to send DNS search list:

```
config system dhcp6 server
  edit 1
    set interface port2
    set upstream-interface WAN
    set ip-mode delegated
    set dns-service delegated
    set dns-search-list delegated // this is a new command
    set subnet 0:0:0:12::/64
  next
end
```

In FortiOS 5.6.1 this feature has been enhanced to include the recursive DNS server option that sends the IPv6 recursive DNS server option to downstream clients with static prefix RA.

The new options include `rdnss` and `dnssl` in the following syntax:

```
config system interface
  edit port1
    config ipv6
      config ip6-prefix-list
        edit 2001:db8::/64
          set autonomous-flag enable
          set onlink-flag enable
          set rdnss 2001:1470:8000::66 2001:1470:8000::72
          set dnssl fortinet.com fortinet.ca
        end
      end
    end
  end
```

### Temporarily mask interface failure (435426)

In some situations during normal operation, attached network equipment may cause a FortiGate interface to appear to have disconnected from the network. And in some cases you may not want the FortiGate interface to detect and respond to the apparent interruption. For example, when Lawful Intercept (LI) devices are inserted/removed from the network path using a switch mechanism the signal is entirely interrupted. That interruption is seen by the FortiGate as an interface failure.

When the network path is interrupted, the FortiGate normally declares that the interface is down. All services using the interface are notified and act accordingly.

This new feature allows the FortiGate interface to temporarily delay detecting that the interface is down. If the connection is restored during the delay period, the FortiGate ignores the interface down condition and services using the interface resume without apparent interruption.

Use the following command to enable and configure the down time for a FortiGate interface:

```
config system interface
  edit port1
    set disconnect-threshold <delay>
  end
```

`<delay>` is the time to wait before sending a notification that this interface is down or disconnected (0 - 1000 ms, default = 0).

### Policy Routes now appear on the routing monitor (411841)

You can go to **Monitor > Routing Monitor** and select Policy to view the active policy routes on your FortiGate.

Refresh	Edit Route	Static & Dynamic <b>Policy</b>					
IP Version	From	Source	To	Destination	Gateway IP	Protocol	Action
4	mgmt1	10.10.10.0/255.255.255.0	Any	0.0.0.0/0.0.0.0	172.20.121.2	Any	Route

### Control how the system behaves during a routing change (408971)

FortiOS allows you to dynamically make routing changes while the FortiGate unit is processing traffic. Routing changes that affect the routing used for current sessions may affect how the FortiGate continues to process the session after the routing change has been made.

Using the following command you can control whether FortiOS keeps (preserves) the routing for the sessions that are using the route or causes the changed routing table to be applied to active sessions, possibly causing their destinations to change.

```
config system interface
  edit port2
    set preserve-session-route {enable | disable}
  end
```

If enabled (the default), all sessions passing through port2 are allowed to finish without being affected by the routing changes. If disabled, when a route changes the new routing table is applied to the active sessions through port2 which may cause their destinations to change.

## Networking (5.6)

New networking features added to FortiOS 5.6.

### New command to get transceiver signal strength (205138)

On most FortiGate models with SFP/SFP+ interfaces you can use the following command to display information about the status of the transceivers installed in the SFP/SFP+ interfaces of the FortiGate.

The command output lists all of SFP/SFP+ interfaces and if they include a transceiver the output displays information about it. The command output also includes details about transceiver operation that can be used to diagnose transmission problems.

```
get system interface transceiver
```

```
...
```

```
Interface port14 - Transceiver is not detected.
```

```
Interface port15 - SFP/SFP+
```

```
Vendor Name   : FIBERXON INC.
Part No.      : FTM-8012C-SLG
Serial No.    : 101680071708917
```

```
Interface port16 - SFP/SFP+
```

```
Vendor Name   : FINISAR CORP.
Part No.      : FCLF-8521-3
Serial No.    : PS62ENQ
```

SFP/SFP+	Temperature	Voltage	Optical	Optical	Optical
Interface	(Celsius)	(Volts)	Tx Bias	Tx Power	Rx Power
			(mA)	(dBm)	(dBm)

```
-----
port15      N/A      N/A      N/A      N/A      N/A
port16      N/A      N/A      N/A      N/A      N/A
++ : high alarm, + : high warning, - : low warning, -- : low alarm, ? : suspect.
```

## New BGP local-AS support (307530)

Use the following command to configure BGP local-AS support:

```
config router bgp
  config neighbor
    edit "neighbor"
      ...
      set local-as 300
      set local-as-no-prepend disable|enable
      set local-as-replace-as disable|enable
    end
```

Enable `local-as-no-prepend` if you do not want to prepend local-as to incoming updates.

Enable `local-as-replace-as` to replace a real AS with local AS in outgoing updates.

## Interface setting removed from SNMP community (310665)

The SNMP GUI has been cleaned up by removing the **Interface** setting.

## RPF checks can be removed from the state evaluation process (311005)

You can remove stateful firewall RPF state checks without fully enabling asymmetric routing. State checks can be disabled on specific interfaces. The following command shows how to disable state checks for traffic received by the wan1 interface.

Disabling state checks makes a FortiGate unit less secure and should only be done with caution.

```
config system interface
  edit wan1
    set src-check disable
  end
```

## BGP graceful-restart-end-on-timer, stale-route, and linkdown-failover options (374140)

If `graceful-end-on-timer` is enabled, the BGP graceful restart process will be stopped upon expiration of the restart timer only.

If `linkdown-failover` is enabled for a BGP neighbor, the neighbor will be down when the outgoing interface is down.

If `stale-route` is enabled for a BGP neighbor, the route learned from the neighbor will be kept for the `graceful-stalepath-time` after the neighbor is down due to hold timer expiration or TCP connection failure.

```
config router bgp
  set graceful-end-on-timer disable|enable
  config neighbor
    edit 192.168.1.1
```

```

        set linkdown-failover disable|enable
        set stale-route disable|enable
    graceful-end-on-timer stops BGP graceful restart process on timer only.

```

`linkdown-failover` and `stale-route` are options to bring down BGP neighbors upon link down and to keep routes for a period after the neighbor is down.

## FQDNs can be destination addresses in static routes (376200)

FQDN firewall addresses can now be used as destination addresses in a static route.

From the GUI, to add a FQDN firewall address (or any other supported type of firewall address) to a static route in the firewall address configuration you must enable the **Static Route Configuration** option. Then when configuring the static route set **Destination** to **Named Address**.

From the CLI, first configure the firewall FQDN address:

```

config firewall address
    edit 'Fortinet-Documentation-Website'
        set type fqdn
        set fqdn docs.fortinet.com
        set allow-routing enable
    end

```

Then add the FQDN address to a static route.

```

config router static
    edit 0
        set dstaddr Fortinet-Documentation-Website
        ...
    end

```

## Priority for Blackhole routes (378232)

You can now add a priority to a blackhole route to change its position relative to kernel routes in the routing table. Use the following command to add a blackhole route with a priority:

```

config router static
    edit 23
        set blackhole enable
        set priority 200
    end

```

## New DDNS refresh interval (383994)

A new DDNS option has been added to configure the FortiGate to refresh DDNS IP addresses by periodically checking the configured DDNS server.

```

config system ddns
    edit 1
        set ddns-server FortiGuardDDNS
        set use-public-ip enable
        set update-interval seconds
    end

```

The default `update-interval` is 300 seconds and the range is 60 to 2592000 seconds.

### Support IPv6 blackhole routes on GUI (388599)

IPv6 blackhole routes are now supported from GUI, go to **Network > Static Routes** and select **Create New > IPv6 Route**.

Choose **Blackhole** for **Device** field.

**New Static Route**

Destination IP/Mask:

Device: ☐ Blackhole

Administrative Distance :

Comments:  0/255

Status: ☒ Enabled ☐ Disabled

### SSL-VPN can use a WAN link load balancing interface (396236)

Virtual-wan-link interface can now be set as a destination interface in SSLVPN policy.

Also SSL-VPN interface can now be set as a source interface for WAN LLB.

### DDNS support for noip.com (399126)

Noip.com, and provider for Dynamic DNS has been added as a supported option for a `ddns-server`.

#### CLI

```
config system ddns
  edit <ddns_ip>
    set ddns-server
      [dyndns.org|dyns.net|ods.org|tzo.com|vavic.com|dipdns.net|now.net.cn||dhs.org|ea
      sydns.com|genericDDNS|FortiGuardDDNS|noip.com]
```

### IPv6 Router Advertisement options for DNS (399406)

This feature is based on [RFC 6106](#) and it adds the ability to obtain DNS search list options from upstream DHCPv6 servers and the ability to send them out through either Router Advertisement or FortiGate's DHCP server.

#### Configuration example:

To get the information from the upstream ISP server:

```
config system interface
  edit wan1
    config ipv6
      set dhcp6-prefix-delegation enable
    next
```

```
next
end
```

To use Routing Advertisement to send the DNS search list:

```
config system interface
edit port 1
config IPv6
set ip6-address 2001:10::/64
set ip6-mode static
set ip6-send-adv enable
config ip6-delegated-prefix-list
edit 1
set upstream-interface WAN
set subnet 0:0:0:11::/64
set autonomous-flag enable
set onlink-flag enable
next
next
end
end
```

To use DHCPv6 server to send DNS search list:

```
config system dhcp6 server
edit 1
set interface port2
set upstream-interface WAN
set ip-mode delegated
set dns-service delegated
set dns-search-list delegated // this is a new command
set subnet 0:0:0:12::/64
next
end
```

## WAN LLB to SD-WAN on GUI (403102)

To be more consistent with current terminology, the term **WAN LLB** has been changed in the GUI to the more recognizable **SD-WAN**.

## New RFCs

The following RFCs are now supported by FortiOS 5.6.3 or the support for these RFCs has been enhanced in FortiOS 5.6.3:

- [RFC 7627](#) Transport Layer Security (TLS) Session Hash and Extended Master Secret Extension (443870)

The following RFCs are now supported by FortiOS 5.6.1 or the support for these RFCs has been enhanced in FortiOS 5.6.1:

- [RFC 6954](#) Using the Elliptic Curve Cryptography (ECC) Brainpool Curves for the Internet Key Exchange Protocol Version 2 (IKEv2) (412795)
- [RFC 6106](#) IPv6 Router Advertisement Options for DNS Configuration (399406)
- [RFC 4787](#) Network Address Translation (NAT) Behavioral Requirements for Unicast UDP (408875)
- Improved enforced secure-renegotiation checks support for [RFC 5746](#) Transport Layer Security (TLS) Renegotiation Indication Extension (422133)
- [RFC 7627](#) Transport Layer Security (TLS) Session Hash and Extended Master Secret Extension (422133)

The following RFCs are now supported by FortiOS 5.6 or the support for these RFCs has been enhanced in FortiOS 5.6:

- [RFC 7427](#) Signature Authentication in the Internet Key Exchange Version 2 (IKEv2) (389001)
- [RFC 7348](#) Virtual eXtensible Local Area Network (VXLAN) or VTEP (289354)
- [RFC 5996 \(section 2.15\)](#) IKEv2 asymmetric authentication (393073)
- [RFC 6106](#) IPv6 Router Advertisement Options for DNS (399406)
- [RFC 7383](#) Internet Key Exchange Protocol Version 2 (IKEv2) Message Fragmentation (371241)
- [RFC 3971](#) IPv6 Secure Neighbor Discovery (SEND) (355946)
- [RFC 6023](#) Childless IKEv2 Initiation (381650)

## Sandbox Integration (5.6.1)

New sandbox integration features added to FortiOS 5.6.1.

### New file extension lists for determining which file types to send to FortiSandbox (379326)

This feature introduces two new file extension lists:

- File extensions to submit to FortiSandbox even though the AV engine says they are unsupported.
- File extensions to exclude from submitting to FortiSandbox even though the AV engine says they are supported.

These lists are configured on the FortiSandbox, not the FortiGate, and are dynamically loaded on the FortiGate via quarantine.

These lists are only file extensions and not file types detected by the AV engine using magic bytes. Pattern matching is done on the extension of the filename only.

---

### Syntax

```
diag sys scanunit reload-fsa-ext
```

### FortiSandbox integration with AntiVirus in quick mode (436380)

FortiSandbox options in an AntiVirus Security Profile in quick scanning mode can now be enabled with CLI commands.

#### CLI syntax

```
config antivirus profile
  edit default
    set ftgd-analytics disable/everything
    set analytics-max-upload 10
    set analytics-wl-filetype 0
    set analytics-bl-filetype 0
    set analytics-db enable/disable
    set scan-mode quick
  end
```

### Security Fabric (5.6.3)

New Security Fabric features added to FortiOS 5.6.3.

## Security Profiles (5.6.3)

New security profile features added to FortiOS 5.6.3.

### Added multiple ports and port range support in the explicit ftp/web proxy (402775)

Added multiple ports and port range support in the explicit ftp/web proxy:

- added new monitor api endpoint for checking whether a list of TCP port ranges is being used, sample usage:  
/api/v2/monitor/system/check-port-availability?port\_ranges=[{"start":8080,"end":8080},{"start":400,"end":600}, {"start":1,"end":200}]&service=webproxy
- added GUI support for port ranges in web-proxy and ftp-proxy settings

### Block access to unsupported FortiClient endpoints (457695)

You can use the following command to deny registration of unsupported FortiClients endpoints. An unsupported FortiClient endpoint means the endpoint is running FortiClient but for some reason not all of the criteria are available to identify the endpoint, or the endpoint may be running an unsupported version of FortiClient. Information required that is not available could include the endpoint's IP address or MAC address is not visible.

```
config endpoint-control setting
    set forticlient-dereg-unsupported-client {enable | disable}
end
```

### Exempt list fix (381762)

The FortiClient Monitor page now shows exempt device types, as opposed to just the device category. FortiOS can now differentiate the three cases both from backend and GUI.

#### Backend changes

Differentiate the three cases:

- exempt by custom device
- exempt by device category
- exempt by device group

#### GUI changes

##### 1. Monitor > FortiClient Monitor page:

- show device exempt reasons as any combination of device, device category, device group, source address.

##### 2. Update REST monitor api

- (URI: /api/v2/monitor/user/device/select?compliance\_visibility=true)
- update "exempt\_reason" field from string to array of strings in json result

## Security Profiles (5.6.1)

New security profile features added to FortiOS 5.6.1.

### FortiGuard WAN IP blacklist service is now online (404859)

The FortiGuard WAN IP blacklist service was not online in FortiOS 5.6.0. In FortiOS 5.6.1, a notification appears on the **Dashboard** when WAN IP is blacklisted. Clicking on the notification brings up the blacklist details.

### Application Control GUI improvements (279956)

An **All Categories** button on the **Security Profiles > Application Control** page makes it easier to apply an action (Monitor, Allow, Block, Quarantine) to all categories at once.

Note that the **All Categories** selector goes blank when any of the actions to be applied to individual categories is manually changed to something different than what was selected for all the categories. The **Unknown Application** action will match the **All Categories** action unless that action is Quarantine, which is unsupported for unknown applications.

### Industrial Application Control signatures (434592)

The application control category Industrial is now controlled by a FortiGuard license and the default disable mask is no longer needed. The special category is also no longer used.

### GUI updates to reflect package and license changes for IPS, Application Control and Industrial signatures (397010)

The following changes have been made to the GUI to reflect changes in the signature databases:

- Application Control signature database information is displayed under on the **System > FortiGuard** page in the FortiCare section.
- The IPS package version and license status are shown in a separate section in **System > FortiGuard** page. A link to manually upload the IPS database signatures has been added.
- The Industrial package version and license status are shown in a separate section in **System > FortiGuard** page. A link to manually upload the Industrial database signatures is available. Access to the Industrial database is provided with the purchase of the FortiGuard Industrial Security Service. The row item for this license will not appear if you are not subscribed.
- Botnet category is no longer available when searching the Application Signatures list.

### Improved FortiClient monitor display (378288)

The GUI for the **Monitor > FortiClient Monitor** page has been revised.

- new dropdown option: **Online Only** or **Include Offline**. The default is **Online Only**.
- new dropdown option
  - **Sending FortiTelemetry Only** (default)
  - **Include All FortiTelemetry States**
  - **Not Sending FortiTelemetry Only**
- update: **Compliance** status for offline device is **N/A**
- update: offline status indicator to grey
- new compliance status text after the icon in **Compliance** column
- Moved **Compliance** column after **Status** column
- Combined unregistered endpoint devices with not registered devices

## FortiSandbox integration with AntiVirus in quick mode (436380)

FortiSandbox options in an AntiVirus Security Profile in quick scanning mode can now be enabled with CLI commands.

### CLI syntax

```
config antivirus profile
  edit default
    set ftgd-analytics disable/everything
    set analytics-max-upload 10
    set analytics-wl-filetype 0
    set analytics-bl-filetype 0
    set analytics-db enable/disable
    set scan-mode quick
  end
```

## Pre-configured parental controls for web filtering (399715)

Pre-configured filters based on the Motion Picture Association of America (MPAA) ratings can now be added to the Web Filter Security Profile. This feature is already available on FortiCloud and uses the same ratings categories.

## Anti-Spam GUI updates (300423)

Changes made to the Anti-Spam profile update the GUI to reflect FortiOS 5.6 style.

## Security Profiles (5.6)

New security profile features added to FortiOS 5.6.

### New FortiGuard Web Filter categories (407574)

New categories added to FortiGuard Web Filter sub-categories:

- Under Security Risk:
  - Newly Observed Domain (5.90)
  - Newly Registered Domain (5.91)
- Under General Interest - Business
  - Charitable Organizations (7.92)
  - Remote Access (7.93)
  - Web Analytics (7.94)
  - Online Meeting (7.95)

Newly observed domain (NOD) applies to URLs whose domain name is not rated and were observed for the first time in the past 30 minutes.

Newly registered domain (NRD) applies to URLs whose domain name was registered in the previous 10 days.

### Overall improvement to SSL inspection performance (405224)

The enabling / disabling of proxy cipher / kxp hardware acceleration in CP8/CP9 required restarting of the WAD daemon for the change to take effect; this bug has been repaired.

## New CLI commands

The FortiGate will use the `ssl-queue-threshold` command to determine the maximum queue size of the CP SSL queue. In other words, if the SSL encryption/decryption task queue size is larger than the threshold, the FortiGate will switch to use CPU rather than CP. If less, it will employ CP.

```
config firewall ssl setting
    set ssl-queue-threshold <integer>
end
```

The integer represents the maximum length of the CP SSL queue. Once the queue is full, the proxy switches cipher functions to the main CPU. The range is 0 - 512 and the default is 32.

## FortiClient Endpoint license updates (401721)

FortiClient endpoint licenses for FortiOS 5.6.0 can be purchased in multiples of 100. There is a maximum client limit based on the FortiGate's model. FortiCare enforces the maximum limits when the customer is applying the license to a model.

If you are using the ten free licenses for FortiClient, support is provided on the Fortinet Forum ([forum.fortinet.com](https://forum.fortinet.com)). Phone support is only available for paid licenses.

Model(s)	Maximum client limit
VM00	200
FGT/FWF 30 to 90 series	200
FGT 100 to 400 series	600
FGT 500 to 900 series, VM01, VM02	2,000
FGT 1000 to 2900 series	20,000
FGT 3000 to 3600 series, VM04	50,000
FGT 3700D and above, VM08 and above	100,000

Older FortiClient SKUs will still be valid and can be applied to FortiOS 5.4 and 5.6.

If you are using the ten free licenses for FortiClient, support is provided on the Fortinet Forum ([forum.fortinet.com](https://forum.fortinet.com)). Phone support is only available for paid licenses.

## FortiClient Vulnerability Exemption Setting (407230)

A new CLI command provides a manual override for client computers with vulnerabilities that cannot be fixed.

### CLI Syntax

New command to enable/disable compliance exemption for vulnerabilities that cannot be auto patched. Default is `disable`.

```

config endpoint-control profile
  edit <profile-name>
    config forticlient-winmac-setting
      set forticlient-vuln-scan enable
      set forticlient-vuln-scan-exempt [enable|disable]
    end
  next
end

```

## DNS profile supports safe search (403275)

Users can take advantage of pre-defined DNS doctor rules to edit DNS profiles and provide safe search for Google, Bing, and YouTube.

### To add safe search to a DNS profile - GUI

1. Go to **Security Profiles > DNS Filter**.
2. Edit the default filter or create a new one.
3. Enable **Enforce 'Safe Search on Google, Bing, YouTube**.
4. Select **Strict** or **Moderate** level of restriction for **YouTube Access**.

### To add safe search to a DNS profile - CLI

```

config dnsfilter profile
  edit "default"
    set safe-search enable
    set youtube-restrict {strict | moderate} (only available is safe-search enabled)
  next
end

```

## Application control and Industrial signatures separate from IPS signatures (382053)

IPS, Application control and industrial signatures have been separated. The get system status command shows the versions of each signature database:

```

get system status
Version: FortiGate-5001D v5.6.0,build1413,170121 (interim)
Virus-DB: 42.00330(2017-01-23 01:16)
Extended DB: 1.00000(2012-10-17 15:46)
Extreme DB: 1.00000(2012-10-17 15:47)
IPS-DB: 6.00741(2015-12-01 02:30)
IPS-ETDB: 0.00000(2001-01-01 00:00)
APP-DB: 6.00741(2015-12-01 02:30)

```

## Changes to default SSL inspection configuration (380736)

SSL inspection is mandatory in the CLI and GUI and is enabled by default.

### GUI Changes

- Updated edit dialogues for IPv4/IPv6 Policy and Explicit Proxy Policy
  - SSL/SSH inspection data displayed in muted palette
  - disabled the toggle button for this option

- set the default profile as "certificate-inspection"
- Updated list pages for IPv4/IPv6 Policy and Explicit Proxy Policy
  - Add validation for "ssl-ssh-profile" when configuring UTM profiles
- Updated SSL/SSH Inspection list page
  - disabled delete menu on GUI for default ssl profiles
  - changed "Edit" menu to "View" menu for default ssl profiles
  - added implicit class (grayed) the default ssl profile entries
- Updated SSL/SSH Inspection edit dialog
  - disabled all the inputs for default ssl profiles except download/view trusted certificate links
  - changed button to "Return" for default ssl profiles to return the list page
- Updated Profile Group edit dialog
  - removed checkbox for "ssl-ssh-profile" option, make it always required.

### CLI changes

1. `ssl-ssh-profile` default value is `certificate-inspection` when applicable in table `firewall.profile-group`, `firewall.policy`, `firewall.policy6`, `firewall.explicit-proxy-policy`
2. make default profiles "certificate-inspection", "deep-ssl-inspection" read only in table `firewall.ssl-ssh-profile`

### Block Google QUIC protocol in default Application Control configuration (385190)

QUIC is an experimental protocol from Google. With recent Google Chrome versions (52 and above), and updated Google services, more than half of connections to Google servers are now in QUIC. This affects the accuracy of Application Control. The default configuration for Application control blocks QUIC.

Users may enable QUIC with CLI commands.

#### CLI Syntax

```
config application list
edit <profile-name>
set options allow-quic
end
```

### Botnet database changes (390756)

Starting in FortiOS 5.6, FortiGate units and FortiGuard Distribution Servers (FDS) will use object IDs IBDB and DBDB to download and update the Botnet database. Botnet protection will be part of the AntiVirus contract.

FortiOS 5.4 uses object IDs IRDB and BDDb.

### Fortinet Security Fabric audit check for endpoint vulnerability and unauthorized FAP and FSW (401462)

The new Security Fabric Audit feature allows for the display of endpoint vulnerability status in real-time. Users can see:

- FortiClient devices that have critical vulnerabilities detected.
- Discovered FortiSwitches that have not yet been authorized.
- Discovered FortiAPs that have not yet been authorized.

## Change to CLI commands for configuring custom Internet services (397029)

Custom internet services are no longer configured through use of the commands `config application internet-service` and `config application internet-service-custom` in the CLI.

These commands are replaced by `config firewall internet-service` and `config firewall internet-service-custom`.

### CLI Syntax - examples

```
config firewall internet-service 1245324
  set name "Fortinet-FortiGuard"
  set reputation 5
  set icon-id 140
  set offset 1602565
  config entry
    edit 1
      set protocol 6
      set port 443
      set ip-range-number 27
      set ip-number 80
    next
    edit 2
      set protocol 6
      set port 8890
      set ip-range-number 27
      set ip-number 80
    next
    edit 3
      set protocol 17
      set port 53
      set ip-range-number 18
      set ip-number 31
    next
    edit 4
      set protocol 17
      set port 8888
      set ip-range-number 18
      set ip-number 31
    next
  end
end
```

```
config firewall internet-service-custom
  edit "custom1"
    set comment "custom1"
    config entry
      edit 1
        set protocol 6
        config port-range
          edit 1
            set start-port 30
            set end-port 33
          next
        next
      next
    end
  end
```

```

        end
        set dst "google-drive" "icloud"
    next
end
next
end

```

### Enable "sync-session-ttl" in "config ips global" CLI by default (399737)

`sync-session-ttl` is now set to `enable` by default in order to:

- enhance detection of P2P traffic. Efficient detection of P2P is important on hardware accelerated platforms
- ensure that IPS and the kernel use the same ttl
- ensure that IPS sessions time out sooner

### CASI functionality moved into application control (385183, 372103)

Cloud Access Security Inspection (CASI) is merged with Application Control resulting in changes to the GUI and the CLI.

#### GUI Changes

- Toggle option added to quickly filter CASI signatures in the Application Signatures list.
- Application Overrides table now shows any parent-child hierarchy using the `--parent` metadata on signatures. Deleting a parent app also deletes its child apps. And conversely, adding a child app will add all its parent apps but with implicit filter action.
- A policy breakdown is shown on existing application control profiles for policies using the profile. The breakdown indicates which policies are using a deep inspection.
- A breakdown is shown for application categories and filter overrides to indicate the number of CASI and non-CASI signatures. A lock icon is shown for applications requiring deep inspection.

#### CLI Changes

Commands removed:

- `config application casi profile`
- `casi profile in config firewall policy`
- `casi profile in config firewall policy6`
- `casi-profile-status and casi-profile under config firewall sniffer`
- `casi-profile-status and casi-profile under config firewall interface-policy`

### New diagnose command to delete avatars (388634)

Commands to delete avatars by FortiClient UID or avatar name have been added to the CLI.

the two following commands has been added to diagnose endpoint avatar:

- `diagnose endpoint avatar delete <ftcl_uid>`
- `diagnose endpoint avatar delete <ftcl_uid> <username>`

The attribute `delete` did not exist before. The values `<fctl_uid>` and `<user_name>` describe a set of avatars. If only `<fctl_uid>` is defined, all avatars belonging to this FortiClient UID that are not being used will be removed. If both values are defined, the avatar belonging to them will be removed unless they are being used in which case this call will cause an error to user.

### Fortinet bar option disabled in profile protocol options when VDOM is in flow-based inspection mode (384953)

In order to prevent the Fortinet Bar from being enabled and redirecting traffic to proxy (WAD) when a VDOM is in flow-based mode, the Fortinet Bar option is disabled in profile protocol options.

### SSL/SSH profile certificate handling changes (373835)

In order to support DSA and ECDSA key exchange (in addition to RSA) in SSL resign and replace mode, CLI commands for `deep-inspection` have changed. The `certname` command in `ssl-ssh-profile` has been removed.

To select from the list of available certificates in the system, use the CLI below.

```
edit deep-inspection
  set server-cert-mode re-sign
  set certname-{rsa | dsa | ecdsa}
```

### Restricting access to YouTube (replacement for the YouTube Education filter feature) (378277)

Previous versions of FortiOS supported YouTube for Schools (YTfS). As of July 1, 2016 this feature is no longer supported by YouTube. Instead you can use the information in the YouTube support article [Restrict YouTube content on your network or managed devices](#) to achieve the same result. FortiOS supports applying **Strict** or **Moderate** restrictions using HTTP headers as described in this article.

In FortiOS 5.6 with inspection mode set to proxy-based, in a Web Filter profile under **Search Engines** you can select **Restrict YouTube Access** and select either **Strict** or **Moderate**.

### Enhancements to IPS Signatures page (285543)

The IPS signatures list page now shows which IPS package is currently deployed. Users can also change their IPS package by linking directly to the FortiGate's **System > FortiGuard** page from the IPS Signatures list page.

### DLP sensor GUI changes (307225)

The DLP sensor for file size has been corrected to indicate that the file size has to be greater than the number of KB entered. Previously, the GUI incorrectly showed that the files size could be greater than or equal to the number of KB entered.

## Web Filter profile page GUI updates (309012)

The GUI for the **Web Filter** security profile and **Web Profile Overrides** pages are changed.

### Web Filter profile page

- removed multilist for override user group and profile
- replaced FortiGuard categories actions icons with font icons
- added tooltip for **Allow users to override blocked categories** to explain the policy group dependency

### Web Profile Overrides page

- removed multilist of user, user group, original profile, new profile
- duplicate profile for new profile (for bug #284239)

## Web Filter Quota traffic can no longer be set to 0 (374380)

To fix a bug in older major release, the CLI has been changed so that minimum traffic quota does not allow 0 as an entry. The value entered must be in the range of 1 - 4,294,967,295; if 0 is entered, then an error message will be returned.

### CLI Commands:

```
config webfilter profile
  edit default
    config ftgd-wf
      config quota
        edit 1
          set type traffic
          set value {a number in the range of 1 - 4,294,967,295}
```

## Webcache-https and SSL deep inspection profile configuration changes (381101)

In older releases, the CLI blocked the configuration of the SSL deep inspection profile when webcache-https was enabled. This bug is fixed in FortiOS 5.6.0.

## FortiGate conserve mode changes (242562, 386503)

The following changes were made to rework **conserve mode** and facilitate its implementation:

- Implemented CLI commands to configure **extreme**, **red**, and **green** memory usage thresholds in percentages of total RAM. Memory used is the criteria for these thresholds, and set at 95% (extreme), 88% (red) and 82% (green).
- Removed structure `av_conserve_mode`, other changes in kernel to obtain and set memory usage thresholds from the kernel
- Added conserve mode diagnostic command `diag hardware sysinfo conserve`, which displays information about memory conserve mode.
- Fixed conserve mode logs in the kernel
- Added conserve mode stats to the proxy daemon through command `diag sys proxy stats all | grep conserve_mode`

### New custom IPS and Application Control Signatures list (280954)

You can now create IPS and Application control custom signatures by going to **Security Profiles > Custom Signatures**. From here you can create and edit all custom IPS and Application Control signatures.

### Default inspection mode set to flow-based (377392)

In FortiOS 5.6.0, the following changes were made to inspection mode:

- factory default sets the FortiGate to flow-based inspection with VDOM disabled
- whenever a VDOM is created, the default inspection mode is flow-based

You must use the CLI to set the FortiGate to proxy-based inspection. To change the inspection mode back to flow-based inspection, you may use the GUI or the CLI.

```
config system settings
    edit <name_str>
        set inspection-mode {proxy | flow}
    end
```

## Server Load balancing (5.6.1)

New load balancing features added to FortiOS 5.6.1.

### Add server load balancing real servers on the Virtual Server GUI page (416709)

In previous versions of the FortiOS GUI, after adding a Virtual Server you would go to **Policy & Objects > Real Servers** to add real servers and associate each real server with a virtual server.

In FortiOS 5.6.1 you now go to **Policy & Objects > Virtual Servers**, configure a virtual server and then from the same GUI page add real servers to the virtual server. In addition, on the Virtual Server GUI page the option **Outgoing Interface** is renamed **Interface** and the load balancing method **Source IP Hash** has been renamed **Static**.

## Edit Virtual Server

Name

Comments  0/255

## Network

Type

Interface

Virtual Server IP

Virtual Server Port

Load Balancing Method

Persistence  **HTTP Cookie**

Health Check

	HTTP check	✕
	Ping-check	✕
		+

HTTP Multiplexing  ☐

Preserve Client IP ☐

## Real Servers

<div> <span>+ Create New</span> <span> Edit</span> <span> Delete</span> </div>				
IP Address	Port	Weight	Max Connections	Mode
10.10.10.1	80	10	0	Active
10.10.10.2	80	10	0	Active
10.10.10.3	80	10	0	Active

## Server Load balancing (5.6)

New load balancing features added to FortiOS 5.6.

### IPv6, 6to4, and 4to6 server load balancing (280073)

Sever load balancing is supported for:

- IPv6 VIPs (`config firewall vip6`)
- IPv6 to IPv4 (6to4) VIPs (`config firewall vip64`)
- IPv4 to IPv6 (4to6) VIPs (`config firewall vip46`)

Configuration is the same as IPv4 VIPs, except support for advanced HTTP and SSL related features is not available. IPv6 server load balancing supports all the same server types as IPv4 server load balancing (HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL, TCP, UDP, and IP). IPv4 to IPv6 and IPv6 to IPv4 server load balancing supports fewer server types (HTTP, TCP, UDP, and IP).

### **Improved Server load balancing GUI pages (404169)**

Server load balancing GUI pages have been updated and now include more functionality and input verification.

## **Session-aware Load Balancing (SLBC) (5.6.1)**

New SLBC features added to FortiOS 5.6.1.

### **FortiController-5000 series independent port splitting (42333)**

FortiOS 5.6.1 supports splitting some 40G FortiController front panel fiber channel front panel interfaces in to 10G ports. In previous versions of FortiOS this configuration was not supported and all FortiController fiber channel front panel interfaces had to operate at the same speed.

## SSL VPN (5.6.3)

New SSL VPN features added to FortiOS 5.6.3.

### Virtual desktop option no longer supported (442044)

The SSL VPN web portal no longer supports the virtual desktop and its option has been removed from the interface.

### Option to disable FortiClient download in web portal (439736)

You can use the following commands to enable or disable allowing SSL VPN users to download FortiClient from the SSL VPN web portal. If `forticlient-download` is enabled, you can select the download method (`direct` or over the `ssl_vpn`). You can also optionally specify a custom URL for downloading the Windows and Mac OS versions of FortiClient.

#### Syntax

```
config vpn ssl web portal
  edit <portal name>
    set forticlient-download {enable | disable}
    set forticlient-download-method {direct | ssl-vpn}
    set customize-forticlient-download-url {enable | disable}
    set windows-forticlient-download-url <url>
    set macos-forticlient-download-url <url>
  end
```

### Upgraded OpenSSL to 1.1.x (412033) (...)

OpenSSL has been upgraded to 1.1 to provide more cryptographic algorithms. All 3rd-party libraries that depend on OpenSSL have also been updated. OpenLDAP has been upgraded to 2.4.45 to be compatible with OpenSSL 1.1. Furthermore, the `ssl_v3` attribute has been removed from `vpn.ssl.settings` and `global.admin-https-ssl-version`.

## SSL VPN (5.6.1)

New SSL VPN features added to FortiOS 5.6.1.

### Added a button to send Ctrl-Alt-Delete to the remote host for VNC and RDP desktop connections (401807)

Previously, users were unable to send **Ctrl-Alt-Delete** to the host machine in an SSL VPN remote desktop connection.

FortiOS 5.6.1 adds a new button that allows users to send **Ctrl-Alt-Delete** in remote desktop tools (also fixes 412456, preserving the SSL VPN realm after session timeout prompts a logout).

### Improved SSL VPN Realms page (0392184)

Implemented minor functional changes to the dialog on the **SSL VPN > Realms** page:

- URL preview uses info message similar to that seen on the SSL VPN settings dialog.
- Virtual-Host input is now visible when set in the CLI.

- Added help tooltip describing what the virtual-host property does.

### Customizable FortiClient Download URL in SSL VPN Web Portal (437883)

A new attribute, `customize-forticlient-download-url`, is added to `vpn.ssl.web.portal`.

The added attribute indicates whether to support a customizable download URI for FortiClient. This attribute is disabled by default. If enabled, two other attributes, `windows-forticlient-download-url` and `macos-forticlient-download-url`, will appear through which the user can customize the download URL for FortiClient.

#### Syntax

```
config vpn ssl web portal
  edit <portal>
    set customize-forticlient-download-url {enable | disable}
    set windows-forticlient-download-url <custom URL for Windows>
    set macos-forticlient-download-url <custom URL for Mac OS>
  next
end
```

### SSL VPN SSO Support for HTML5 RDP (417248)

This feature adds support for SSO from the SSL VPN portal to an RDP bookmark. If SSO is used, then the credentials used to login to SSL VPN will be automatically used when connecting to a remote RDP server.

#### Syntax

```
conf vpn ssl web user-bookmark
  edit <name>
    config bookmarks
      edit <name>
        set apptype rdp
        set host "x.x.x.x"
        set port <value>
        set sso [disable | auto]
      next
    end
  next
end
```

## SSL VPN (5.6)

New SSL VPN features added to FortiOS 5.6.

### Remote desktop configuration changes (410648)

If NLA security is chosen when creating an RDP bookmark, a username and password must be provided. However there may be instances where the user might want to use a blank password, despite being highly unrecommended. If a username is provided but the password is empty, the CLI will display a warning. See example CLI below, where the warning appears as a caution before finishing the command:

```
config vpn ssl web user-group-bookmark
  edit <group-name>
    config bookmarks
      edit <bookmark-name>
```

```

        set apptype rdp
        set host 172.16.200.121
        set security nla
        set port 3389
        set logon-user <username>
    next
end

```

**Warning: password is empty. It might fail user authentication and remote desktop connection would be failed.**

end

If no username (logon-user) is specified, the following warning message will appear:

```

Please enter user name for RDP security method NLA. object set operator error, -2010
discard the setting Command fail. Return code -2010

```

### SSL VPN supports WAN link load balancing interface (396236)

This new feature allows you to set `virtual-wan-link` as the destination interface in a firewall policy (when SSL VPN is the source interface) for WAN link load balancing in the GUI and in the CLI. This lets you log into a FortiGate via SSL VPN for traffic inspection and then have outbound traffic load balanced by WAN link load balancing.

#### Syntax

```

config firewall policy
    edit <example>
        set dstintf virtual-wan-link
    end

```

### SSL VPN login timeout to support high latency (394583)

With long network latency, the FortiGate can timeout the client before it can finish negotiation processes, such as DNS lookup and time to enter a token. Two new CLI commands under `config vpn ssl settings` have been added that allow the login timeout to be configured, replacing the previous hard timeout value. The second command can be used to set the SSL VPN maximum DTLS hello timeout.

#### Syntax

```

config vpn ssl settings
    edit <example>
        set login-timeout [10-180] Default is 30 seconds.
        set dtls-hello-timeout [10-60] Default is 10 seconds.
    end

```

### SSL VPN supports Windows 10 OS check (387276)

A new CLI field has been added to the `os-check-list` under `config vpn ssl web portal` to allow OS checking for Windows 10.

#### Syntax

```

config vpn ssl web portal
    edit <example>
        set os-check enable
        config os-check-list windows-10
            set action {deny | allow | check-up-to-date}
        end
    end

```

```
end
end
```

### SSL VPN DNS suffix per portal and number of portals (383754)

A new CLI command under `config vpn ssl web portal` to implement a DNS suffix per SSL VPN portal. Each suffix setting for each specific portal will override the `dns-suffix` setting under `config vpn ssl settings`.

This feature also raises bookmark limits and the number of portals that can be supported, depending on what FortiGate series model is used:

- 650 portals on 1000D series
- 1300 portals on 2000E series
- 2600 portals on 3000D series

The previous limit for 1000D series models, for example, was 256 portals.

#### Syntax

```
config vpn ssl web portal
  edit <example>
    set dns-suffix <string>
  end
```

### New SSL VPN timeout settings (379870)

New SSL VPN timeout settings have been introduced to counter 'Slowloris' and 'R-U-Dead-Yet' vulnerabilities that allow remote attackers to cause a denial of service via partial HTTP requests.

The FortiGate solution is to add two attributes (`http-request-header-timeout` and `http-request-body-timeout`).

#### Syntax

```
config vpn ssl settings
  set http-request-header-timeout [1-60] (seconds)
  set http-request-body-timeout [1-60] (seconds)
end
```

### Personal bookmark improvements (377500)

You can now move and clone personal bookmarks in the GUI and CLI.

#### Syntax

```
config vpn ssl web user-bookmark
  edit 'name'
    config bookmarks
      move bookmark1 after/before
      clone bookmark1 to
    next
  end
```

### New controls for SSL VPN client login limits (376983)

Removed the limitation of SSL VPN user login failure time, by linking SSL VPN user setting with `config user settings` and provided a new option to remove SSL VPN login attempts limitation. New CLI allows the administrator to configure the number of times wrong credentials are allowed before SSL VPN server blocks an IP address, and also how long the block would last.

#### Syntax

```
config vpn ssl settings
  set login-attempt-limit [0-10] Default is 2.
  set login-block-time [0-86400] Default is 60 seconds.
end
```

### Unrated category removed from ssl-exempt (356428)

The "Unrated" category has been removed from the SSL Exempt/Web Category list.

### Clipboard support for SSL VPN remote desktop connections (307465)

A remote desktop clipboard viewer pane has been added which allows user to copy, interact with and overwrite remote desktop clipboard contents.

## System (5.6.3)

New system administration features added to FortiOS 5.6.3.

## System (5.6.1)

New system administration features added to FortiOS 5.6.1.

### Use self-sign as default GUI certificate if BIOS cert is using SHA-1 (403152)

For increased security, SHA-1 certificate has been replaced by self-sign certificate as the default GUI certificate, if the BIOS certificate is using SHA-1.

### Administrator timeout override per access profile (413543)

The GUI is often used for central monitoring. To do this requires the inactivity timeout to be increased, to avoid an admin having to constantly log in over again. This new feature allows the **admintimeout** value, under `config system accprofile`, to be overridden per access profile.

Note that this can be achieved on a per-profile basis, to avoid the option from being unintentionally set globally.

#### CLI Syntax - Configure admin timeout

```
config system accprofile
  edit <name>
    set admintimeout-override {enable | disable}
    set admintimeout <0-480> - (default = 10, 0 = unlimited)
  next
end
```

### New execute script command (423159)

A new `execute` command has been introduced to merge arbitrary configlets into the running configuration from script. The command's authentication can be carried out using either username and password or with a certificate. This command supports FTP/TFTP and SCP.

An important benefit of this feature is that if the configuration in the script fails (i.e. a syntax error), the system will revert back to running configurations without interrupting the network.

#### CLI Syntax - Load script from FTP/TFTP/SCP server to firewall

```
execute restore scripts <ftp | tftp |
  scp> <dir / filename in server> <server ip> <username> <password>
```

## System (5.6)

New system administration features added to FortiOS 5.6.

### Remove CLI commands from 1-CPU platforms (405321)

Two CLI commands that set CPU affinity have been removed from 1-CPU platforms since they do not have any impact on these platforms. The commands are `config system global > set miglog-affinity` and `config system global > set av-affinity <string>`.

### New SNMP trap for bypass events (307329)

When bypass mode is enabled or disabled on FortiGate units that are equipped with bypass interfaces and support AMC modules, a new SNMP trap is generated and logs bypass events.

### Implement SNMP support for NAT Session monitoring which includes new SNMP OIDs (383661)

FortiOS 5.6 implements a new feature providing SNMP support for NAT session monitoring. The resulting new SNMP object identifier (OID) is:

FORTINET-FORTIGATE-

MIB:fortinet.fnFortiGateMib.fgFirewall.fgFwIppools.fgFwIppTables.fgFwIppStatsTable.fgFwIppStatsEntry  
1.3.6.1.4.1.12356.101.5.3.2.1.1

Additionally, there are eight new items:

- .fgFwIppStatsName .1
- .fgFwIppStatsType .2
- .fgFwIppStatsStartIp .3
- .fgFwIppStatsEndIp .4
- .fgFwIppStatsTotalSessions .5
- .fgFwIppStatsTcpSessions .6
- .fgFwIppStatsUdpSessions .7
- .fgFwIppStatsOtherSessions .8

### New extended database version OIDs for AV and IPS (402162)

New extended database version OIDs ensure accurate display of the AntiVirus and IPS databases in use when you go to **System > FortiGuard**.

### Administrator password encryption hash upgraded from SHA1 to SHA256 (391576)

The encryption for administrator passwords is upgraded from SHA1 to SHA256.

Downgrades from FortiOS 5.6->5.4->5.2->5.0 will keep the administrator password usable. If you need to downgrade to FortiOS 4.3, remove the password before the downgrade, then login after the downgrade and re-set password.

### Allow multiple FortiManager addresses when configuring central management (388083)

Central management configuration can now support multiple FortiManager addresses. This feature is mainly to help the case where the FortiGate unit is behind NAT.

### FortiGuard can determine a FortiGate's location from its public IP address (393972)

A new CLI command allows users to determine a FortiGate's location from its public IP address through FortiGuard.

The new CLI command is `diagnose system waninfo`.

### Deletion of multiple saved configurations supported (308936)

The FortiGate will save multiple configurations and images when `revision-backup-on-logout` and `revision-image-auto-backup` are enabled in `config system global`.

The deletion of multiple saved configurations is now possible due to changes in the CLI command `execute revision delete config <revision ID>`. Where the command only allowed for one revision ID at a time, it now allows almost ten.

### New CLI option to limit script output size (388221)

The new CLI command `set output-size` limits the size of an auto script in megabytes and prevents the memory from being used up by the script's output.

#### CLI Syntax

```
config system auto-script
  edit <script name>
    set output-size <integer>
  next
end
```

Enter an integer value from 10 to 1024. Default is 10.

### Enable / disable logging of SSL connection events (375582)

New CLI commands are added to give the user the option to enable or disable logging of SSL connection events.

#### CLI Syntax

```
config system global
  set log-ssl-connection {enable | disable}
end
```

Default is `disable`.

### Enabling or disabling static key ciphers (379616)

There is a new option in `system global` to enable or disable static key ciphers in SSL/TLS connections (e.g., AES128-SHA, AES256-SHA, AES128-SHA256, AES256-SHA256). The default is `enable`.

#### CLI Syntax

```
config system global
  set ssl-static-key-ciphers {enable | disable}
end
```

## Enhancements to IPS Signatures page (285543)

The IPS signatures list page now shows which IPS package is currently deployed. You can also change the IPS package by hovering over the information icon next to the IPS package name. Text appears that links directly to the FortiGate's **System > FortiGuard** page from the IPS Signatures list page.

## Combine multiple commands into a CLI alias (308921)

You can add one or more CLI command to a CLI alias, then use the `alias` command to run the alias that you have created to execute the stored commands. For example, create the following `alias` to run the `get system status` command:

```
config system alias
  edit "version"
    set command "get system status"
  end
```

Then you can use the following command to run the alias:

```
alias version
```

You can use command abbreviations (for example: `g sys stat` instead of `get system status`). Use quotes around the syntax if there are spaces (there usually are).

You can enter `alias` followed by a `?` to view the aliases that you have added.

You can add multiple commands to an alias by pressing **Ctrl-Enter** after the first line. Press enter at the end of subsequent lines. And the end of the last line add second quote and press Enter to end the command.

```
config system alias
  edit "debug_flow"
    set command "diag debug enable"
    diag debug flow show console enable"
  end
```

You can include config commands in an alias as well, for example, create the following alias to bring the port1 and port2 interfaces down:

```
config system alias
  edit port12down
    set command "config system interface
    edit port1
    set status down
    next
    edit port2
    set status down
    end"
  end
```

You can combine `config`, `execute`, `get`, and `diagnose` commands in the same alias, for example:

```
config system alias
  edit "show-info"
    set command "show full-configuration alertemail setting
    get sys status
    dia sys top"
  end
```

## Traffic shaping (5.6.3)

### Support schedule on traffic shaping policy (450337)

In FortiOS 5.6, a new traffic "shaping-policy" feature was added, but it lacked the ability to apply different shaping profiles at different times. This feature addresses this issue by adding a "schedule" attribute to the shaping policy.

This feature is currently only available via the CLI, and you can use this feature to apply a reoccurring schedule to your traffic shaping policies. The default recurring schedule options available are **always** or **none**. You can also create new schedules or schedule groups under **Policy & Objects > Schedules**. This allows you to create custom recurring or one-time schedules that can then be applied to your traffic shaping policies using the commands below.

#### Syntax

```
config firewall shaping-policy
  edit <shaping policy ID>
    set schedule {always | none}
  end
```

## VDOMs (5.6.0)

This section describes new VDOM features added to FortiOS 5.6

### Dashboard changes

The option to enable VDOMs is no longer part of the **System Information** widget. To enable VDOMs, you must now go to **System > Settings**.

### Firewall Service Cache improvement

The Firewall Service Cache will now have separate caches for each VDOM, to improve the speed of cache searches.

## VoIP/SIP (5.6)

This chapter describes new VoIP and SIP features added to FortiOS 5.6.

### SIP strict-register enabled by default in VoIP Profiles (380830)

If `strict-register` is disabled, when REGISTER is received by a FortiGate, the source address (usually the IP address of PBX) and ports (usually port 5060) are translated by NAT to the external address of the FortiGate and port 65476. Pinholes are then opened for SIP and RTP. This tells the SIP provider to send incoming SIP traffic to the external address of the FortiGate on port 65476.

This creates a security hole since the port is open regardless of the source IP address so an attacker who scans all the ports by sending REGISTER messages to the external IP of the FortiGate will eventually have one register go through.

When `strict-register` is enabled (the new default) the pinhole is smaller because it will only accept packets from the SIP server.

Enabling `strict-register` can cause problems when the SIP registrar and SIP proxy server are separate entities with separate IP addresses.

### SIP diagnose command improvements (376853)

A diagnose command has been added to the CLI that outputs VDOM data located in the voipd daemon.

```
diagnose sys sip-proxy vdom
```

### Example

```
(global) # diagnose sys sip-proxy vdom
VDOM list by id:
vdom 0 root (Kernel: root)
vdom 1 dmngmt-vdom (Kernel: dmngmt-vdom)
vdom 2 test2 (Kernel: test2)
vdom 3 test3 (Kernel: test3)
vdom 4 vdoma2 (Kernel: vdoma2)
vdom 5 vdomb2 (Kernel: vdomb2)
vdom 6 vdomc2 (Kernel: vdomc2)
vdom 7 vdoma (Kernel: vdoma)
vdom 8 vdomb (Kernel: vdomb)
vdom 9 vdomc (Kernel: vdomc)
```

```
VDOM list by name:
vdom 1 dmngmt-vdom (Kernel: dmngmt-vdom)
vdom 0 root (Kernel: root)
vdom 2 test2 (Kernel: test2)
vdom 3 test3 (Kernel: test3)
vdom 7 vdoma (Kernel: vdoma)
vdom 4 vdoma2 (Kernel: vdoma2)
vdom 8 vdomb (Kernel: vdomb)
vdom 5 vdomb2 (Kernel: vdomb2)
vdom 9 vdomc (Kernel: vdomc)
vdom 6 vdomc2 (Kernel: vdomc2)
```

### WiFi (5.6.3)

New WiFi features added to FortiOS 5.6.3.

#### Allow admin with write permission to see plain text WiFi password (249787, 434513, 452834, 458211, 458285)

Add support for admins with write permission to read plain text password. Admins can view these plain text passwords (`captive-portal-radius-secret` and `passphrase`) under `config wireless-controller vap`. Note that security must be set as a WPA-personal setting.

#### WiFi Health Monitor page updates (392574, 392585, 404341, 417039, 434141, 440709)

The **WiFi Health Monitor** page list of active clients now shows their MAC address entries (similar to the **WiFi Client Monitor** page), making client information easier to view when opening the **Active Client** widget.

#### FortiAP LED Schedules (436227)

Support has been added for WTP profile LED schedules.

Use the command below (`led-schedule`) to assign recurring firewall schedules for illuminating LEDs on the FortiAP. This entry is only available when `led-state` is enabled, at which point LEDs will be visible when at least one of the schedules is valid.

Separate multiple schedule names with a space, as configured under `config firewall schedule group` and `config firewall schedule recurring`.

#### Syntax

```
config wireless-controller wtp-profile
  edit {name}
    set led-state {enable | disable}
    set led-schedules <name>
  next
end
```

#### Sharing Tunnel SSIDs within a single managed AP between VDOMs as a Virtual AP for multi-tenancy (439751)

Support has been added for the ability to move a tunnel mode VAP into a VDOM, similar to an interface/VLAN in VDOMs.

FortiAP is registered into the root VDOM. Within a customer VDOM, customer VAPs can be created/added. In the root VDOM, the customer VAP can be added to the registered FortiAP. Any necessary firewall rules and interfaces can be configured between the two VDOMs.

#### Syntax

```
config wireless-controller global
  set wtp-share {enable | disable}
end
```

### 30D/30E models support two normal-mode FAPs (446122)

Fixed an issue that blocked FortiGate 30D and 30E models from supporting two normal-mode FortiAPs.

### MAC Bypass for Captive Portal (448296)

Support has been added to provide a MAC address bypass for authenticated clients. Previously, when clients were authenticated with bridged SSID and their MAC addresses were known, they were not redirected to the External Captive Portal.

A new portal type has been added, under `config wireless-controller vap`, to provide successful MAC authentication Captive Portal functionality.

#### Syntax

```
config wireless-controller vap
  edit {name}
    set portal-type {cmcc-macauth}
  next
end
```

### WiFi Health Monitor fixes (449341)

An issue has been addressed where the **Client Count** widget (under **WiFi Health Monitor**) showed wrong options for the timeline selection.

The fixes include:

- Fixed timeline selection options to correct values.
- Updated time filter parameters with correct arguments in the **Login Failures** widget.
- Added local radio to **AP Status** widget details.
- Fixed **Login Failures** widget, where the SSID name was improperly formatted if it contained HTML characters.

### Various bug fixes (452975, 455218, 453161, 405117, 453533, 453535, 184384)

Various fixes have been implemented to address a variety of issues:

The fixes include:

- Removed code to avoid repeated printing "parse dhcp options" after upgrade or reboot.
- Removed code that supported FAP-C221E, C226E, and C21D, as their product names changed.
- Changed the text for incorrect WiFi CLI help descriptions.
- Fixed background scan settings for FAP 222C, 223C, 321C, C220C, C225C, C23JD, and C24JE.
- Set WTP entry with "discovered" state to built-in in order to skip them, as only managed FAPs can be counted toward FAP capacity.

### Configure how a FortiWiFi WiFi interface in client mode selects a WiFi band (455305)

For an FortiWiFi WiFi interface operating in client mode, you can use the following option to configure the WiFi band that the interface can connect to. You can configure the interface to connect to any band, just to the 5G band or to prefer connecting to the 5G band.

## Syntax

```
config system interface
  edit {name}
    set wifi-ap-band {any | 5g-preferred | 5g-only}
  next
end
```

## WiFi (5.6.1)

New WiFi features added to FortiOS 5.6.1.

### Support for various FortiAP models (416177) (435638) (424483)

FortiAP units FAP-U321EV, FAP-U323EV, FAP-S221E, FAP-S223E, FAP-222E, FAP-221E, and FAP-223E are supported by FortiOS 5.6.1.

As part of this support, new CLI attributes have been added under `config wireless-controller wtp-profile` to manage their profiles.

### CLI syntax

```
config wireless-controller wtp-profile
  edit <model>
    config platform
      set type <model>
    end
    set ap-country <code>
    config radio-1
      set band 802.11n
    end
    config radio-2
      set band 802.11ac
    end
  next
end
```

### New Managed AP Groups and Dynamic VLAN Assignment (436267)

The FortiGate can create FortiAP Groups, under **WiFi & Switch Controller > Managed Devices > Managed FortiAPs** by selecting **Create New > Managed AP Group**, where multiple APs can be managed. AP grouping allows specific profile settings to be applied to many APs all at once that belong to a certain AP group, simplifying the administrative workload.

Note that each AP can only belong to one group.

In addition, VLANs can be assigned dynamically based on the group which an AP belongs. When defining an SSID, under **WiFi & Switch Controller > SSID**, a setting called **VLAN Pooling** can be enabled where you can either assign the VLAN ID of the AP group the device is connected to, to each device as it is detected, or to always assign the same VLAN ID to a specific device. Dynamic VLAN assignment allows the same SSID to be deployed to many APs, avoiding the need to produce multiple SSIDs.

## GUI support for configuring multiple pre-shared keys for SSID interfaces (406321)

Multiple pre-shared keys can be created per SSID. When creating a new SSID, enable **Multiple Pre-shared Keys** under **WiFi Settings**.

## FortiAP Bluetooth Low Energy (BLE) Scan (438274)

The FortiGate can configure FortiAP Bluetooth Low Energy (BLE) scan, incorporating Google's BLE beacon profile known as Eddystone, used to identify groups of devices and individual devices.

Currently, only the FAP-S221E, FAP-S223E, and FAP-222E models support this feature.

As part of this support, new CLI attributes have been added under `config wireless-controller timers` and `config wireless-controller wtp-profile`, including a new CLI command, `config wireless-controller ble-profile`.

### CLI syntax - Configure BLE profiles

```
config wireless-controller ble-profile
  edit <name>
    set comment <comment>
    set advertising {ibeacon | eddystone-uid | eddystone-url}
    set ibeacon-uuid <uuid>
    set major-id <0 - 65535> - (default = 1000)
    set minor-id <0 - 65535> - (default = 1000)
    set eddystone-namespace <10-byte namespace>
    set eddystone-instance <device id>
    set eddystone-url <url>
    set txpower <0 - 12> - (default = 0)
    set beacon-interval <40 - 3500> - (default = 100)
    set ble-scanning {enable | disable} - (default = disable)
  next
end
```

Note that `txpower` determines the transmit power level on a scale of 0-12:

<b>0:</b> -21 dBm	<b>1:</b> -18 dBm	<b>2:</b> -15 dBm	<b>3:</b> -12 dBm	<b>4:</b> -9 dBm
<b>5:</b> -6 dBm	<b>6:</b> -3 dBm	<b>7:</b> 0 dBm	<b>8:</b> 1 dBm	<b>9:</b> 2 dBm
<b>10:</b> 3 dBm	<b>11:</b> 4 dBm	<b>12:</b> 5 dBm		

### CLI syntax - Configure BLE report intervals

```
config wireless-controller timers
  set ble-scan-report-intv - (default = 30 sec)
end
```

### CLI syntax - Assign BLE profiles to WTP profiles

```
config wireless-controller wtp-profile
```

```
edit <name>
    set ble-profile <name>
next
end
```

### WiFi client monitor page search enhanced (440709)

WiFi Client Monitor page (**Monitor > WiFi Client Monitor**) now supports search function.

## WiFi (5.6)

New WiFi features added to FortiOS 5.6.

### Captive Portal Authentication with FortiAP in Bridge Mode (408915)

The FortiGate can operate as a web captive portal server to serve the captive portal local bridge mode.

A new CLI command has been added under `config wireless-controller vap` to set the captive portal type to CMCC, a wireless cipher.

#### CLI syntax

```
config wireless-controller vap
edit <name>
    set portal-type { ... | cmcc }
next
end
```

### 802.11kv(r) support (405498, 395037)

New CLI commands have been added under `config wireless-controller vap` to set various 802.11kv settings, or Voice Enterprise (802.11kv) and Fast Basic Service Set (BSS) Transition (802.11r), to provide faster and more intelligent roaming for the client.

#### CLI syntax

```
config wireless-controller vap
edit <name>
    set voice-enterprise {enable | disable}
    set fast-bss-transition {enable | disable}
    set ft-mobility-domain
    set ft-r0-key-lifetime [1-65535]
    set ft-over-ds {enable | disable}
next
end
```

### External Captive Portal authentication with FortiAP in Bridge Mode (403115, 384872)

New CLI commands have been added under `config wireless-controller vap` to set various options for external captive portal with FortiAP in Bridge Mode. The commands set the standalone captive portal server category, the server's domain name or IP address, secret key to access the RADIUS server, and the standalone captive portal Access Controller (AC) name.

Note that these commands are only available when **local-standalone** is set to **enable** and **security** is set to **captive-portal**.

**CLI syntax**

```

config wireless-controller vap
  edit <name>
    set captive-portal-category {FortiCloud | CMCC} Default is FortiCloud.
    set captive-portal-radius-server <server>
    set captive-portal-radius-secret <password>
    set captive-portal-ac-name <name>
  next
end

```

**Japan DFS support for FAP-421E/423E/S421E/S423E (402287, 401434)**

Korea and Japan Dynamic Frequency Selection (DFS) certification has been added for FAP-421E/423E/S421E/S423E. DFS is a mechanism that allows WLANs to select a frequency that does not interfere with certain radar systems while operating in the 5 GHz band.

**802.3az support on WAVE2 WiFi APs (400558)**

A new CLI command has been added under `config wireless-controller wtp-profile` to enable or disable use of Energy-Efficient Ethernet (EEE) on WTP, allowing for less power consumption during periods of low data activity.

**CLI syntax**

```

config wireless-controller wtp-profile
  edit <profile-name>
    set energy-efficient-ethernet {enable|disable}
  end

```

**CLI command update made in wids-profile (400263)**

The CLI command `rogue-scan` under `config wireless-controller wids-profile` has been changed to `sensor-mode` and allows easier configuration of radio sensor mode. Note that while `foreign` enables radio sensor mode on foreign channels only, `both` enables the feature on foreign and home channels.

**CLI syntax**

```

config wireless-controller wids-profile
  edit <example>
    set sensor-mode {disable|foreign|both}
  end

```

**Channel utilization, FortiPresence support on AP mode, QoS enhancement for voice (399134, 377562)**

A new CLI command has been added, `config wireless-controller qos-profile`, to configure quality of service (QoS) profiles where you can add WiFi multi-media (WMM) control and Differentiated Services Code Point (DSCP) mapping.

Note that:

- `call-capacity` and `bandwidth-admission-control` are only available when `call-admission-control` is set to enable.

- bandwidth-capacity is only available when bandwidth-admission-control is set to enable.
- All DSCP mapping options are only available when dscp-wmm-mapping is set to enable.
- wmm is already set to enable by default. If wmm is set to disable, the following entries are *not* available: wmm-uapsd, call-admission-control, and dscp-wmm-mapping.

### CLI syntax

```
config wireless-controller qos-profile
edit <example>
    set comment <comment>
    set uplink [0-2097152] Default is 0 Kbps.
    set downlink [0-2097152] Default is 0 Kbps.
    set uplink-sta [0-2097152] Default is 0 Kbps.
    set downlink-sta [0-2097152] Default is 0 Kbps.
    set burst {enable|disable} Default is disable.
    set wmm {enable|disable} Default is enable.
    set wmm-uapsd {enable|disable} Default is enable.
    set call-admission-control {enable|disable} Default is disable.
    set call-capacity [0-60] Default is 10 phones.
    set bandwidth-admission-control {enable|disable} Default is disable.
    set bandwidth-capacity [1-600000] Default is 2000 Kbps.
    set dscp-wmm-mapping {enable|disable} Default is disable.
    set dscp-wmm-vo [0-63] Default is 48 56.
    set dscp-wmm-vi [0-63] Default is 32 40.
    set dscp-wmm-be [0-63] Default is 0 24.
    set dscp-wmm-bk [0-63] Default is 8 16.
```

QoS profiles can be assigned under the `config wireless-controller vap` command using `qos-profile`.

FortiCloud managed APs can now be applied a bandwidth restriction or rate limitation based on SSID. For instance if guest and employee SSIDs are available, you can rate limit guest access to a certain rate to accommodate for employees. This feature also applies a rate limit based on the application in use, as APs are application aware.

### FAP-U421E and FAP-U423E support (397900)

Two Universal FortiAP models support FortiOS 5.6. Their default profiles are added under `config wireless-controller wtp-profiles`, as shown below:

### CLI syntax

```
config wireless-controller wtp-profile
edit "FAPU421E-default"
    config platform
        set type U421E
    end
    set ap-country US
    config radio-1
        set band 802.11n
    end
    config radio-2
        set band 802.11ac
    end
next
end
```

```

config wireless-controller wtp-profile
  edit "FAPU423E-default"
    config platform
      set type U423E
    end
    set ap-country US
    config radio-1
      set band 802.11n
    end
    config radio-2
      set band 802.11ac
    end
  next
end

```

### Minor reorganization of WiFi GUI entries (396497)

**WiFi & Switch Controller** GUI entries **Managed FortiAPs**, **SSID**, **FortiAP Profiles**, and **WIDS Profiles** have been reorganized.

### Multiple PSK support for WPA personal (393320, 264744)

New CLI commands have been added, under `config wireless-controller vap`, to configure multiple WiFi Protected Access Pre-Shared Keys (WPA-PSKs), as PSK is more secure without all devices having to share the same PSK.

Note that, for the following multiple PSK related commands to become available, `vdom`, `ssid`, and `passphrase` all have to be set first.

#### CLI syntax

```

config wireless-controller vap
  edit <example>
    set mpsk {enable|disable}
    set mpsk-concurrent-clients [0-65535] Default is 0.
    config mpsk-key
      edit key-name <example>
        set passphrase <wpa-psk>
        set concurrent-clients [0-65535] Default is empty.
        set comment <comments>
      next
    end
  next
end

```

Use the `mps-k-concurrent-clients` entry to set the maximum number of concurrent connected clients for each `mps-k` entry. Use the `mps-k-key` configuration method to configure multiple `mps-k` entries.

### Table size of qos-profile has VDOM limit (388070)

The command `config wireless-controller qos-profile` now has VDOM table limit; there is no longer an unlimited number of entries within each VDOM.

### Add "dhcp-lease-time" setting to local-standalone-nat VAP (384229)

When a Virtual Access Point (VAP) has been configured for a FortiAP, a DHCP server is automatically configured on the FortiAP side with a hard lease time. A new CLI command under `config wireless-controller vap` has been added to customize the DHCP lease time for NAT IP address. This is to solve issues where the DHCP IP pool was exhausted when the number of clients grew too large for the lease time span.

Note that the new command, `dhcp-lease-time`, is only available when `local-standalone` is set to `enable`, then setting `local-standalone-nat` to `enable`.

#### CLI syntax

```
config wireless-controller vap
  edit <example>
    set local-standalone {enable|disable}
    set local-standalone-nat {enable|disable}
    set dhcp-lease-time [300-8640000] Default is 2400 seconds.
  end
```

### New CLI command to configure LDPC for FortiAP (383864)

Previously, LDPC value on FortiAP could only be changed on FortiAP local CLI. Syntax has been added in FortiOS CLI under the 'wireless-controller.vap' entry to configure the LDPC value on FortiAP.

#### CLI Syntax

```
configure wireless-controller vap
  edit 1
    set ldpc [enable|rx|tx|disable]
  end
```

### New region code/SKU for Indonesia (382926)

A new country region code, F, has been added to meet Indonesia's WiFi channel requirements. Indonesia previously belonged to region code W.

### FortiAP RMA support added (381936)

New CLI command `fortiap` added under `exe replace-device` to replace an old FortiAP's serial number with a new one.

#### CLI Syntax

```
execute replace-device fortiap <old-fortiap-id> <new-fortiap-id>
```

### Support fixed-length 64-hex digit for WPA-Personal passphrase (381030)

WPA-Personal passphrase now supports a fixed-length of 64 hexadecimal digits.

### Allow FortiGates to manage cloud-based FortiAPs (380150)

FortiGates can now manage cloud-based FortiAPs using the new `fapc-compatibility` command under `wireless-controller` setting.

If enabled, default FAP-C wtp-profiles will be added. If disabled, FAP-C related CMDDB configurations will be removed: wtp-group in vap's vlan-pool, wtp-group, ws, wtp, wtp-profile.

### CLI syntax

```
config wireless-controller setting
  set country CN
  set fapc-compatibility [enable|disable]
end
```

You will receive an error message when trying to change `country` while `fapc-compatibility` is enabled. You need to disable `fapc-compatibility` before changing to an FAPC unsupported country.

### Use IPsec instead of DTLS to protect CAPWAP tunnels (379502)

This feature is to utilize FortiAP hardware to improve the throughput of tunneled data traffic by using IPsec when data security is enabled.

"AES-256-CBC & SHA256" algorithm and "dh\_group 15" are used for both CAPWAP IPsec phase1 and phase 2.

FAP320B will not support this feature due to its limited capacity of free flash.

### New option added to support only one IP per one endpoint association (378207)

When users change configuration, the radiusd will reset all configurations and refresh all logons in the kernel. All these actions are done in the one loop. A CLI option has been added to enable/disable replacement of an old IP address with a new IP address for the same endpoint on RADIUS accounting start.

### CLI Syntax

```
configure user radius
  edit radius-root
    set rsso-ep-one-ip-only [enable|disable]
  next
end
```

### FAP-222C-K DFS support (377795)

Dynamic Frequency Selection (DFS) bands can now be configured for FortiAP 222C-K.

Note that this FortiAP model has the Korean region code (K), but `ap-country` under `config wireless-controller wtp-profile` still needs to be set to KR.

### CLI syntax

```
config wireless-controller wtp-profile
  edit <K-FAP222C>
    config platform
      set type <222C>
    end
    set ap-country KR
    config radio-2
      set band <802.11ac>
      set vap-all <disable>
```

```

        set vaps "vap-vd-07"
        set channel "52" "56" "60" "64" "100" "104" "108" "112" "116" "120" "124" "128"
            "132" "136" "140"
    end
next
end

```

### Dynamic VLAN support in standalone mode (377298)

Dynamic VLAN is now supported in standalone mode. Previously, dynamic VLAN only worked in local bridge mode.

### CLI-only features added to GUI (376891)

Previously CLI-only features have been added to the GUI under **FortiAP Profiles**, **Managed FortiAPs**, and **SSID**. Also fixed issue where the correct value is displayed when viewing the **WIDS Profile** notification icon under **FortiAP Profiles**.

### Managed AP GUI update (375376)

Upgraded Managed FortiAPs dialog page to a newer style, including icons for SSID and LAN port.

### Bonjour gateway support (373659)

Bonjour gateway now supported for WiFi networks.

#### Syntax

```

config wireless-controller bonjour-profile
edit 0
    set comment "comment"
    config policy-list
    edit 1
        set description "description"
        set from-vlan [0-4094] Default is 0.
        set to-vlan [0-4094|all] Default is all.
        set services [all|airplay|afp|bit-
            torrent|ftp|ichat|itunes|printers|samba|scanners|ssh|chromecast]
    next
end
next
end

```

### FAP421E/423E wave2 support (371374)

Previously removed wave2 FAP421E and FAP423E models have been reinstated and are now supported again. The models are available again through the CLI and GUI. These models are listed under the **Platform** dropdown menu when creating a new FortiAP Profile under **WiFi & Switch Controller > FortiAP Profiles**.

#### CLI syntax

```

config wireless-controller wtp-profile
edit <example>
    config platform
        set type <...|421E|423E>
    end
end

```

## WiFi Health Monitor GUI changes (308317)

The Wifi Health Monitor page has been improved, including the following changes:

- Flowchart used for diagrams
- Chart used for interference and AP clients
- Removed spectrum analysis
- Added functionality to upgrade FortiAP firmware
- Added option to view both 2.4GHz and 5GHz data simultaneously

## AP Profile GUI page updates (298266)

The AP Profile GUI page has been upgraded to a new style including AngularJS code.

## 1+1 Wireless Controller HA (294656)

Instances of failover between FortiAP units was too long and lead to extended periods of time where WiFi users were without network connection. Because WiFi is considered a primary network connection in today's verticals (including enterprise, retail, education, warehousing, healthcare, government, and more), it is necessary for successful failover to occur as fast as possible.

You can now define the role of the primary and secondary controllers on the FortiAP unit, allowing the unit to decide the order in which the FortiAP selects the FortiGate. This process was previously decided on load-based detection, but can now be defined by each unit's pre-determined priority. In addition, heartbeat intervals have been lowered to further improve FortiAP awareness and successful failover.

### Syntax

```
config wireless-controller inter-controller
  set inter-controller-mode {disable | l2-roaming | 1+1} Default is disable.
  set inter-controller-key <password>
  set inter-controller-pri {primary | secondary} Default is primary.
  set fast-failover-max [3-64] Default is 10.
  set fast-failover-wait [10-86400] Default is 10.
  config inter-controller-peer
    edit <name>
      set peer-ip <ip-address>
      set peer-port [1024-49150] Default is 5246.
      set peer-priority {primary | secondary} Default is primary.
    next
  end
end
```

## Support for duplicate SSID names on tunnel and bridge mode interfaces (278955)

When `duplicate-ssid` is enabled in the CLI, this feature allows VAPs to use the same SSID name in the same VDOM. When disabled, all SSIDs in WLAN interface will be checked—if duplicate SSIDs exist, an error message will be displayed. When `duplicate-ssid` is enabled in the CLI, duplicate SSID check is removed in "Edit SSID" GUI page.

### Syntax

```
config wireless-controller setting
  set duplicate-ssid [enable|disable]
```

```
next  
end
```

### **Controlled failover between wireless controllers (249515)**

Instances of failover between FortiAP units was too long and lead to extended periods of time where WiFi users were without network connection. Because WiFi is considered a primary network connection in today's verticals (including enterprise, retail, education, warehousing, healthcare, government, and more), it is necessary for successful failover to occur as fast as possible.

Administrators can now define the role of the primary and secondary controllers on the FortiAP unit, allowing the unit to decide the order in which the FortiAP selects the FortiGate. This process was decided on load-based detection, but can now be defined by each unit's pre-determined priority. In addition, heartbeat intervals have been lowered to further improve FortiAP awareness and successful failover.

## Chapter 2 - Getting Started

- [Installation](#) discusses installing a FortiGate in your network.
- [Using the GUI](#) highlights features of the graphical user interface (GUI).
- [Using the CLI](#) provides a high level overview of the command line interface (CLI) for FortiOS.
- [FortiExplorer for iOS](#) provides instructions for connecting to a FortiGate using the FortiExplorer for iOS app.
- [FortiGate Inspection Mode](#) summarizes proxy-based and flow-based inspection modes.
- [Fortigate LED Specifications](#) presents a short guide to LED status indicators.
- [Basic Administration](#) explains basic tasks for setting up a new FortiGate and for updating firmware.
- [Resources](#) provides a list of documents to help you with more advanced FortiGate configurations.

### Differences between Models

Before you get started, note that not all FortiGate models have the same features. This is especially true of the desktop or entry-level models: FortiGate / FortiWiFi models 30 to 90. If you are using one of these FortiGate models, you may have some difficulties accessing certain features.

Preliminary information on [entry-level models](#) is available below:

The entry-level, or desktop, models can connect to the internet in two simple steps. They also have a number of features that are only available using the CLI, rather than appearing in the GUI.

- [Quick installation using DHCP](#)
- [CLI-only features](#)

Consult your model's Quick Start Guide, [hardware manual](#), or the [Feature / Platform Matrix](#) for further information about features that vary by model.

---

Fortinet's Cookbook site has a section on [hardware](#) that provides how-to recipes and articles on features that are unique to certain models.

FortiGate models differ principally by the names used and the features available:

- Naming conventions may vary between FortiGate models. For example, on some models the hardware switch interface used for the local area network is called **lan**, while on other units it is called **internal**.
- Certain features are not available on all models. Additionally, a particular feature may be available only through the CLI on some models, while that same feature may be viewed in the GUI on other models.

If you believe your FortiGate model supports a feature that does not appear in the GUI, go to **System > Feature Visibility** and confirm that the feature is enabled. For more information, see [Feature Visibility on page 295](#).

## What's New in FortiOS 5.6

This chapter describes new features added to FortiOS 5.6.0, 5.6.1, and 5.6.3.

### FortiOS 5.6.3

These features first appeared in FortiOS 5.6.3.

#### Administrator password changes (414927)

The existing Change Password dialog that appears in the GUI is updated to reflect the new look of the password change prompt at login.

- Added inline validation for checking password policy and password reuse
- Changed style to match new login prompt password change
- Fixed issue where fDialog would close slide out on submission failure

#### Support FortiOS to allow user to select domain when logging a FG into FortiCloud (452350)

Support has been added to show a list of all possible FortiCloud domains that the FortiGate can be served by.

#### Syntax

```
execute fortiguard-log domain
```

This command is typically used for testing purposes, and so it will not appear when entering `execute fortiguard-log ?`.

### FortiOS 5.6.1

These features first appeared in FortiOS 5.6.1.

#### VM License visibility improvement (423347)

VM License GUI items have changed as follows:

- Added VM widget to **Global > Dashboard**. Includes the following:
  - License status and type.
  - CPU allocation usage.
  - License RAM usage.
  - VMX license information (if the VM supports VMX).
  - If the VM license specifies 'unlimited' the progress bar is blank.
  - If the VM is in evaluation mode, it is yellow (warning style) and the dashboard show evaluation days used.
- Widget is shown by default in the dashboard of a FortiOS VM device.
- Removed VM information from License widget at **Global > Dashboard**.
- License info and **Upload License** button provided on page **Global > System > FortiGuard**.
- Updated 'Upload VM License' page:

- Added license RAM usage and VMX instance usage.
- Replaced file input component.

## CLI Syntax

```
config sys admin
  edit <name>
    config gui-dashboard
      edit <1>
        set name <name>
        config widget
          edit <2>
            set type {vminfo | ...} <- new option
            set x-pos <2>
            set y-pos <1>
            set width <1>
            set height <1>
          next
        end
      next
    end
  next
end
```

## FortiView Dashboard Widget (434179)

Added a new widget type to the dashboard for top level FortiView. FortiView widgets have report-by, sort-by, visualization, timeframe properties, and filters subtable in the CLI.

Supported FortiViews include Source, Destination, Application, Country, Interfaces, Policy, Wifi Client, Traffic Shaper, Endpoint Vulnerability, Cloud User, Threats, VPN, Websites, and Admin and System Events.

Bubble, table, chord chart, and country visualizations are supported in the widget.

Widgets can be saved from a filtered FortiView page on to a dashboard.

## Syntax

```
config system admin
  config gui-dashboard
    config widget
      set type fortiview
      set report-by {source | destination | country | intfpair | srcintf | dstintf |
        policy | wificlient | shaper | endpoint | application | cloud | web | threat
        | system | unauth | admin | vpn}
      set timeframe {realtime | 5min | hour | day | week}
      set sort-by <string>
      set visualization {table | bubble | country | chord}
      config filters
        set key <filter_key>
        set value <filter_value>
      end
    end
  end
end
end
```

Where:

- `report-by` = Field to aggregate the data by.
- `timeframe` = Timeframe period of reported data.
- `sort-by` = Field to sort the data by.
- `visualization` = Visualization to use.

### Controls added to GUI CLI console (422623)

FortiOS 5.6.1 introduces new options in the browser CLI console to export the console history. Options are now available to **Clear console**, **Download**, and **Copy to clipboard**.

### FortiExplorer icon enhancement (423838)

FortiOS icons and colors are now exportable in the GUI shared project and FortiExplorer now uses these icons and colors. This change improves the icon colors only for the FortiExplorer GUI theme (seen only when accessing a web GUI page from within the FortiExplorer iOS app).

The following locations were affected: Policy List, Policy Dialogue, Address List, Address Dialogue, Virtual IP list, Virtual IP Dialogue.

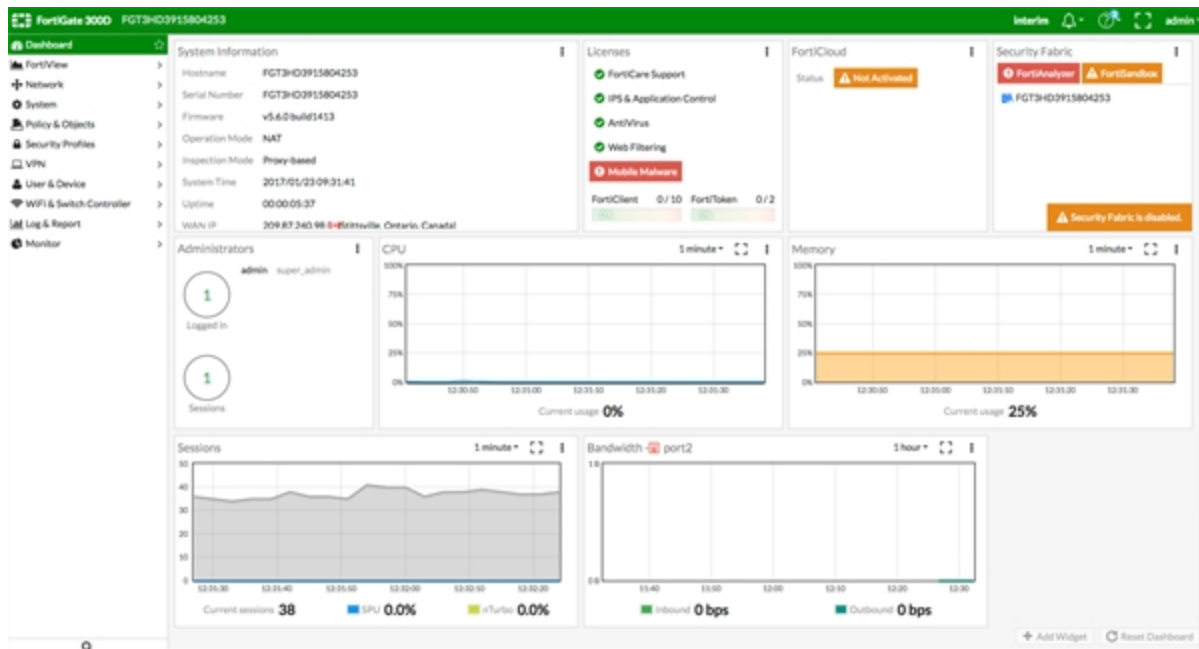

## FortiOS 5.6

These features first appeared in FortiOS 5.6.

The FortiOS 5.6 **Dashboard** has a new layout with a Network Operations Center (NOC) view with a focus on alerts. Widgets are interactive; by clicking or hovering over most widgets, the user can get additional information or follow links to other pages.

Enhancements to the GUI dashboard and its widgets are:

- Multiple dashboard support.
- VDOM and global dashboards.
- Updated resize control for widgets.
- Notifications moved to the top header bar (moved existing dashboard notifications to the header and added additional ones).
- Reorganization of **Add Widget** dialog.
- New **Host Scan Summary** widget.
- New **Vulnerabilities Summary** widget that displays endpoint vulnerability information much like the FortiClient Enterprise Management Server (EMS) summary.
- Multiple bug fixes.

Features that were only visible through old dashboard widgets have been placed elsewhere in the GUI:

- Restore configuration.
- Configuration revisions.
- Firmware management.
- Enabling / disabling VDOMs.
- Changing inspection mode.
- Changing operation mode.
- Shutdown / restart device.
- Changing hostname.
- Changing system time.

The following **widgets** are displayed by default:

- [System Information](#)
- [Licenses](#)
- [FortiCloud](#)
- [Security Fabric](#)
- [Administrators](#)
- [CPU](#)
- [Memory](#)
- [Sessions](#)
- [Bandwidth](#)
- [Virtual Machine](#) (on VMs and new to FortiOS 5.6.1)

The following **optional** widgets are available:

- Interface Bandwidth
- Disk Usage

- Security Fabric Risk
- Advanced Threat Protection Statistics
- Log Rate
- Session Rate
- Sensor Information
- HA Status
- Host Scan Summary
- Vulnerabilities Summary
- FortiView (new to FortiOS 5.6.1)

The following widgets have been **removed**:

- CLI Console
- Unit Operation
- Alert Message Console

## System Information

**System Information**

Hostname	FG100D3G15818864
Serial Number	FG100D3G15818864
Firmware	v5.6.0 build1435
Mode	NAT (Proxy-based)
System Time	2017/03/22 14:05:04
Uptime	00:00:31:34
WAN IP	209.87.240.98 (🇨🇦 Kanata, Ontario, Canada)

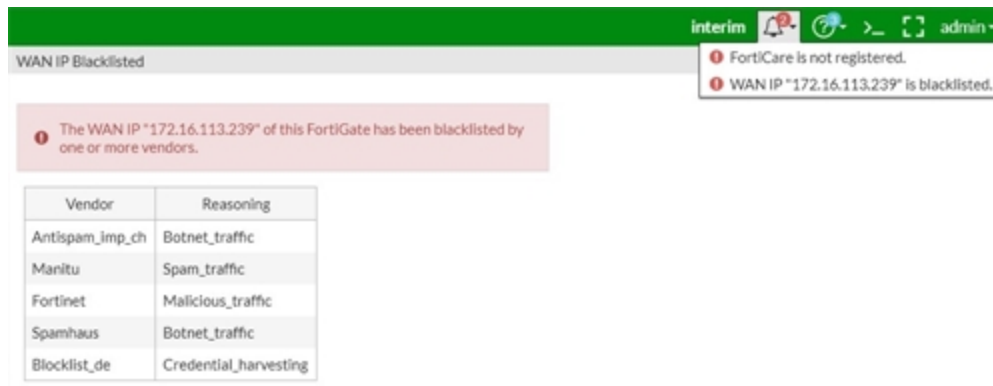

Configure settings in System > Settings

Update firmware in System > Firmware

Only appears when you click on the widget. Click on the System page you want to go to.

## FortiGuard WAN IP blacklist service is now online

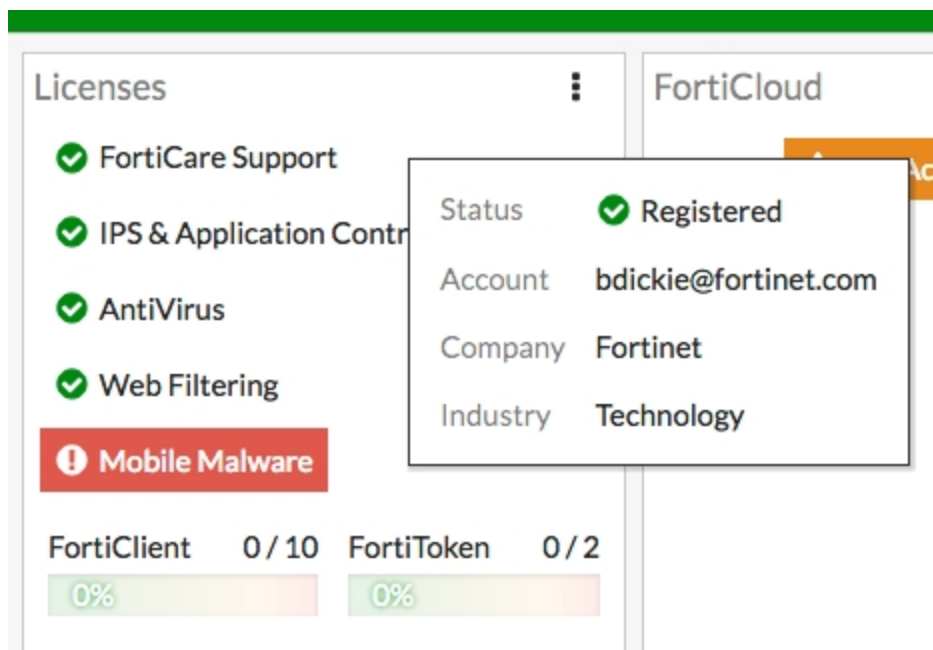

The Fortiguard WAN IP blacklist service was not online in FortiOS 5.6.0. In FortiOS 5.6.1, a notification appears on the **Dashboard** when WAN IP is blacklisted. Clicking on the notification (bell icon) brings up the blacklist details.

## Licenses

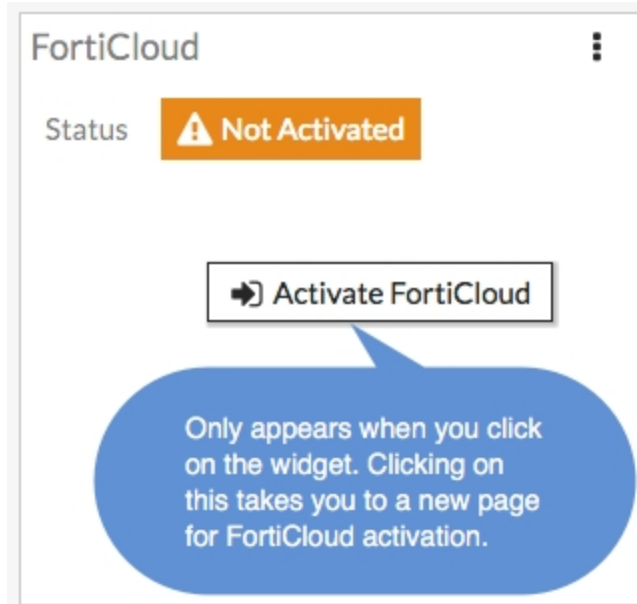

Hovering over the **Licenses** widget will cause status information (and, where applicable, database information) on the licenses to be displayed for **FortiCare Support**, **IPS & Application Control**, **AntiVirus**, **Web Filtering**, **Mobile Malware**, and **FortiClient**. The image below shows **FortiCare Support** information along with the registrant's company name and industry.

Clicking in the **Licenses** widget will provide you with links to other pages, such as **System > FortiGuard** or contract renewal pages.

## FortiCloud

This widget displays FortiCloud status and provides a link to activate FortiCloud.

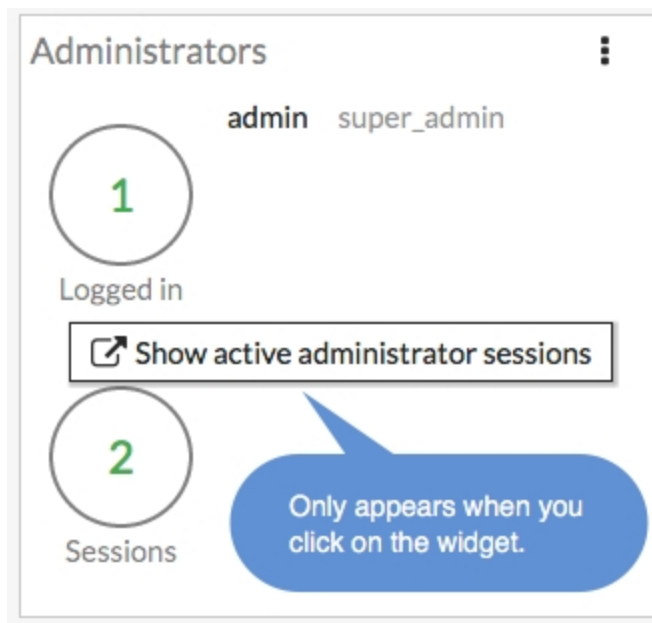

### Fortinet Security Fabric

The **Security Fabric** widget is documented in the [Security Fabric](#) section of the **What's New** document.

### Administrators

This widget allows you to view which administrators are logged in and how many sessions are active. The link directs you to a page displaying active administrator sessions.

### CPU

The real-time CPU usage is displayed for different timeframes.

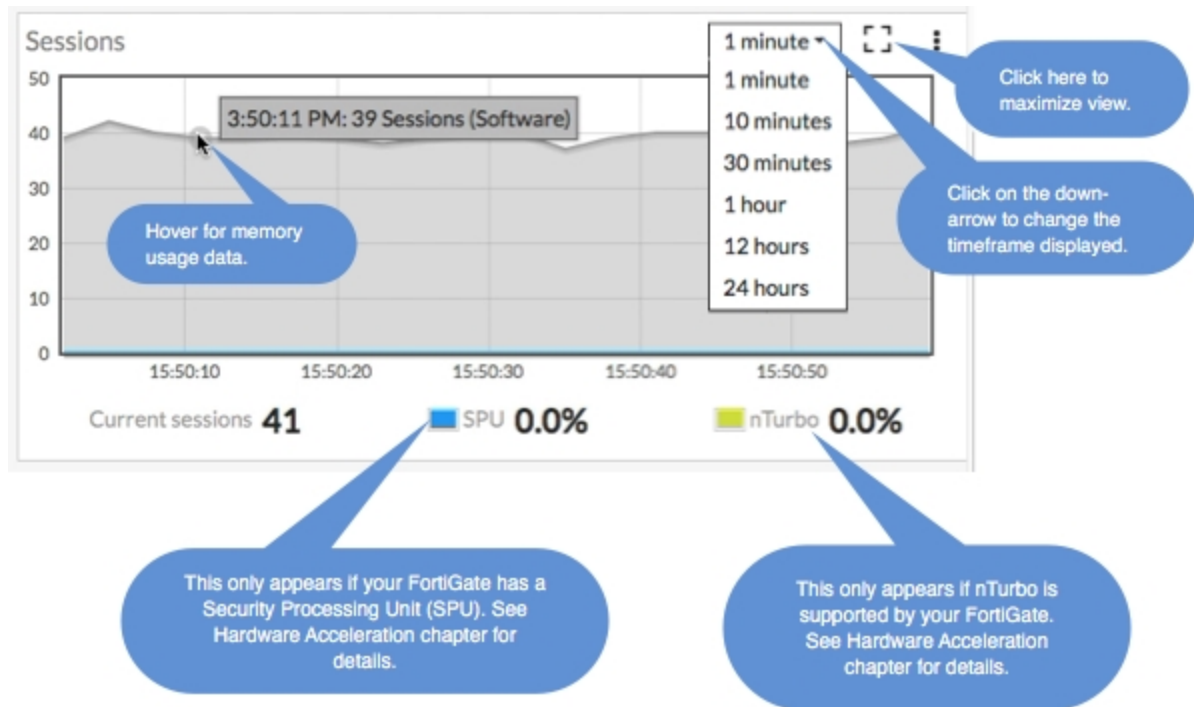

## Memory

Real-time memory usage is displayed for different time frames. Hovering over any point on the graph displays percentage of memory used along with a timestamp.

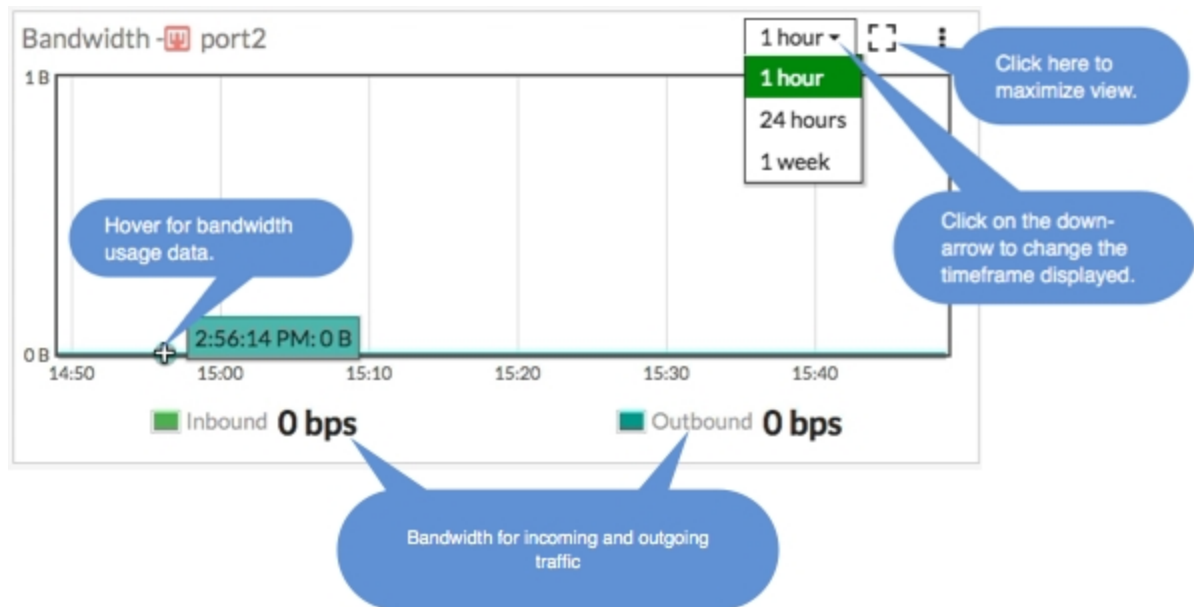

## Sessions

## Bandwidth

## Virtual Machine

FortiOS 5.6.1 introduces a VM widget with these features:

- License status and type.
- CPU allocation usage.
- License RAM usage.
- VMX license information (if the VM supports VMX).
- If the VM license specifies 'unlimited' the progress bar is blank.
- If the VM is in evaluation mode, it is yellow (warning style) and the dashboard show evaluation days used.
- Widget is shown by default in the dashboard of a FortiOS VM device.
- Removed VM information from License widget at **Global > Dashboard**.
- License info and **Upload License** button provided on page **Global > System > FortiGuard**.
- Updated 'Upload VM License' page:
  - Added license RAM usage and VMX instance usage.
  - Replaced file input component.

## Changing inspection modes (flow-based or proxy-based)

To change inspection modes, go to **System > Settings** and scroll down to **Inspection Mode**. You can select Flow-based to operate in Flow mode or Proxy to operate in Proxy mode. Flow-based inspection is the default inspection mode for FortiOS 5.6.

Inspection Mode    Flow-based    **Proxy**

## Transparent Web proxy mode

In proxy mode, FortiOS 5.6 functions just like FortiOS 5.4 with the addition of the new Transparent Web Proxy mode. See [Transparent web proxy \(386474\)](#) on page 83.

## NGFW profile-based and NGFW policy-based modes

When you use **Flow-based** as the **Inspection Mode**, you have the option in FortiOS 5.6 to select an **NGFW Mode**. **Profile-based** mode works the same as flow-based mode did in FortiOS 5.4

**Flow-based** inspection with profile-based **NGFW mode** is the default in FortiOS 5.6.

In the new **NGFW Policy-based** mode, you add applications and web filtering profiles directly to a policy without having to first create and configure Application Control or Web Filtering profiles. When selecting NGFW policy-based mode you can also select the SSL/SSH Inspection mode that is applied to all policies. See [NGFW Policy Mode \(397035\)](#) on page 91.

Inspection Mode	<div>Flow-based</div> <div>Proxy</div>
NGFW Mode	<div>Profile-based</div> <div>Policy-based</div>
SSL/SSH Inspection	<div>SSL</div> <div>deep-inspection</div>

When you use flow-based inspection, all proxy mode profiles are converted to flow mode, removing any proxy settings. And proxy-mode only features (for example, Web Application Profile) are removed from the GUI.

If your FortiGate has multiple VDOMs, you can set the inspection mode independently for each VDOM. Go to **System > VDOM**. Click **Edit** for the VDOM you wish to change and select the **Inspection Mode**.

### CLI syntax

The following CLI commands can be used to configure inspection and policy modes:

```
config system settings
  set inspection-mode {proxy | flow}
  set policy-mode {standard | ngfw}
end
```

## Change to CLI console (396225)

The CLI Console widget has been removed from FortiOS 5.6.0. It is accessed from the upper-right hand corner of the screen and is no longer a pop-out window but a sliding window.

## System Information Dashboard widget WAN IP Information enhancement (401464)

WAN IP and location data are now available in the **System Information** widget. Additionally, If the WAN IP is blacklisted in the FortiGuard server, there will be a notification in the notification area, located in the upper right-hand corner of the **Dashboard**. Clicking on the notification will open the WAN IP Blacklisted slider with the relevant blacklist information.

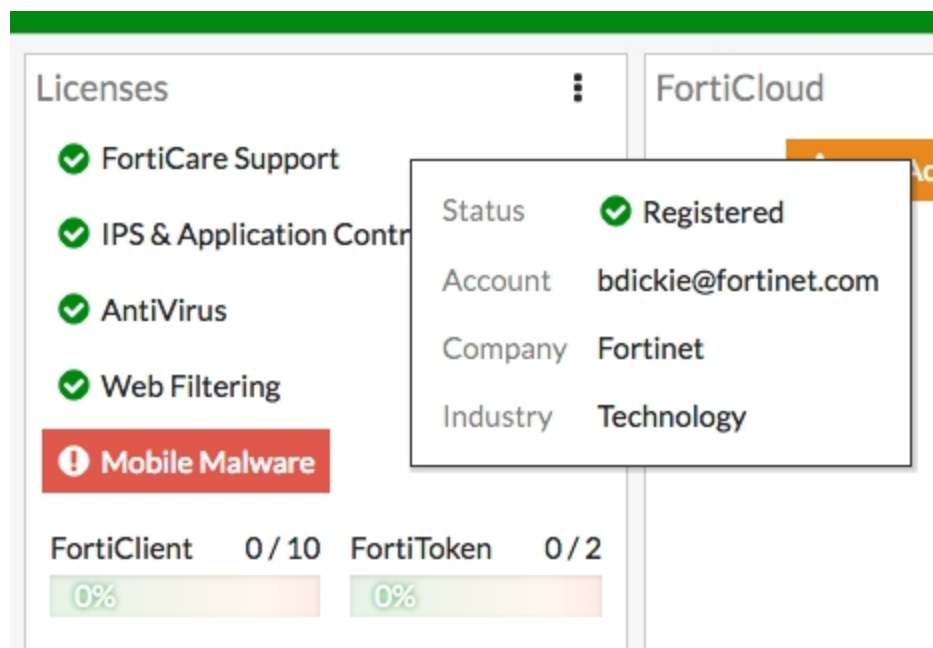

## CLI and GUI changes to display FortiCare registration information (395254)

The changes pertain to industry and organization size of the FortiGate's registered owner.

### GUI Changes

- Add industry and organization size to FortiCare registration page
- Add company and industry to license widget tooltip for FortiCare

When you hover over the Licenses widget in the FortiOS 5.6 dashboard, you can see the company and industry data, provided it has been entered in the FortiCare profile.

### CLI Changes

Commands are added to diagnose forticare

```

dia forticare direct-registration product-registration -h
Options: a:A:y:C:c:T:eF:f:hI:i:l:O:o:p:P:z:R:r:S:s:t:v:
--&long& -&short&
account_id a:
address A:
city y:
company C:
contract_number c:
country_code T:
existing_account e
fax F:
first_name f:
help h

```

```
industry I:
industry_id i:
last_name l:
orgsize O:
orgsize_id o:
password p:
phone P:
postal_code z:
reseller R:
reseller_id r:
state S:
state_code s:
title t:
version v:
```

### Improved GUI for Mobile Screen Size & Touch Interface (355558)

The FortiOS web GUI on mobile screens and include functionality for touch interfaces like tap to hold are improved.

### Setup Wizard removed

Previously, the Setup Wizard could be launched from the web GUI by selecting the  button, located in the top right corner. This button and the wizard in question has been removed.

## Installation

This section discusses how to install your FortiGate and use it in your network, after completion of the initial setup outlined in the FortiGate model's Quick Start Guide.

The following topics are included in this section:

- [Quick installation using DHCP](#)
- [Installing a FortiGate in NAT/Route mode](#)
- [Using a Virtual Wire Pair](#)

## Quick installation using DHCP

Most of the FortiGate desktop models have a default configuration that includes a DHCP server on the **lan** (or **internal**) interface and a security policy that securely allows all sessions from the internal network to reach the Internet. Because of this, you can connect your desktop FortiGate to the Internet in two simple steps:

Note that, in order to use this installation method, your ISP must provide connectivity with DHCP and accept DHCP requests without authentication. You must also use IPv4 to connect your FortiGate to the Internet.

---

1. Connect the FortiGate's **wan** interface to your ISP-supplied equipment, and connect the internal network to the FortiGate's default **lan** interface. Turn on the ISP's equipment, the FortiGate, and the computers on the internal network.
2. For computers on the internal network:
  - a. **Windows Vista/7/8/10 users:**
    - i. Go to **Network and Sharing Center** and select **Change adapter settings**.
    - ii. Open the **Local Area Connection** (Ethernet or Wi-Fi, whichever applies) and select **Properties**.
    - iii. Select **Internet Protocol Version 4 (TCP/IPv4)** and then select **Properties**.
    - iv. Select **Obtain an IP address automatically** and **Obtain DNS server address automatically**.
    - v. Click **OK**.
  - b. **Mac OS X users:**
    - i. Go to **System Preferences > Network** and select your Ethernet connection.
    - ii. Set **Configure IPv4** to **Using DHCP**.

### Results

From any computer on the internal network, open a web browser and browse to any website to confirm successful Internet connectivity.

## Installing a FortiGate in NAT/Route mode

There are two main ways to install a FortiGate using network address translation (NAT)/Route mode: [Standard installation in NAT/Route mode](#), where Internet access is provided by a single Internet service provider (ISP), and [Redundant Internet installation](#), where two ISPs are used.

### NAT/Route mode vs. Transparent mode

A FortiGate can operate in one of two modes: NAT/Route or Transparent.

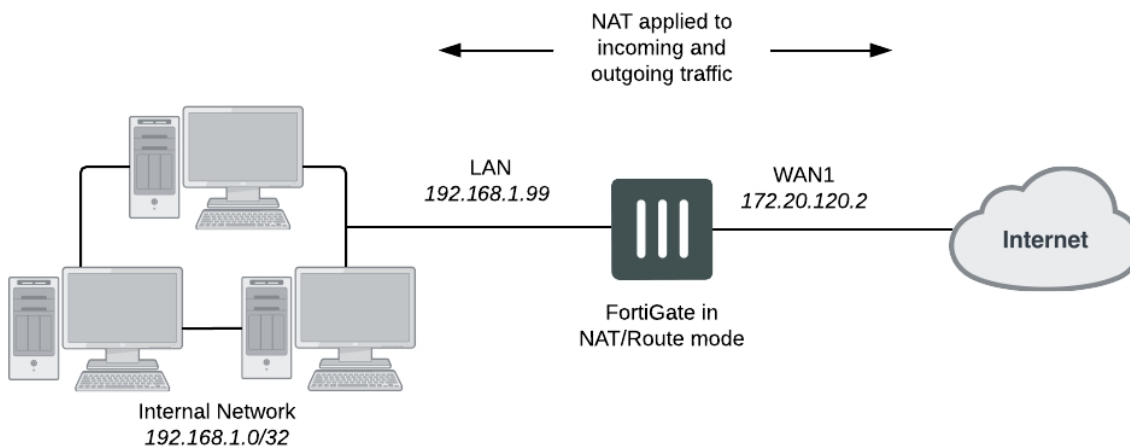

The most common of the two operating modes is NAT/Route mode, where a FortiGate is installed as a gateway or router between two networks. In most cases, it is used between a private network and the Internet. This allows the FortiGate to hide the IP addresses of the private network using NAT. NAT/Route mode is also used when two or more ISPs provide the FortiGate with redundant Internet connections.

A FortiGate in Transparent mode is installed between the internal network and the router. In this mode, the FortiGate does not make any changes to IP addresses and only applies security scanning to traffic. When a FortiGate is added to a network in Transparent mode, no network changes are required, except to provide the FortiGate with a management IP address. Transparent mode is used primarily when there is a need to increase network protection but changing the configuration of the network itself is impractical.

For more information about Transparent Mode, see the [Transparent Mode](#) handbook.

### Standard installation in NAT/Route mode

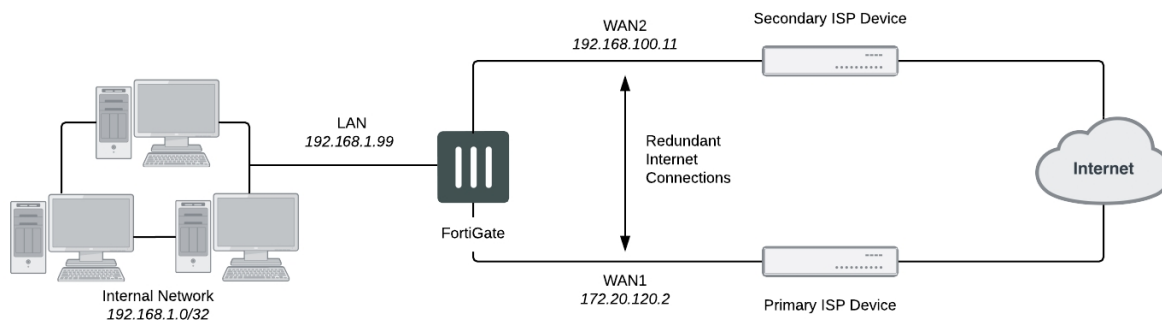

In this configuration, a FortiGate is installed as a gateway or router between a private network and the Internet. By using NAT, the FortiGate is able to hide the IP addresses of the private network.

### Redundant Internet installation

In this configuration, a WAN link interface is created that provides the FortiGate with redundant Internet connections from two ISPs. The WAN link interface combines these two connections, allowing the FortiGate to treat them as a single interface.

## Installing a FortiGate with Redundant Internet

If you have previously configured your FortiGate using the standard installation, you will have to delete all routes and policies referring to an interface that will be used to provide redundant Internet. This includes the default Internet access policy that is included on many FortiGate models.

1. Connect your ISP devices to your FortiGate's Internet-facing interfaces (typically WAN1 and WAN2).
2. Go to **Network > SD-WAN** to create a WAN link interface, which is used to group multiple Internet connections together so that the FortiGate can treat them as a single interface.
3. Set the interface's **Status** to **Enable**.
4. Under **Interface**, select **Create New**. Add WAN1 and enter the Gateway IP provided by your primary ISP. Do the same for WAN2, but use the Gateway IP provided by your secondary ISP.
5. Select an appropriate method for the **SD-WAN Usage** from the following options, and **Apply** your changes when finished:
  - **Bandwidth** - A bandwidth cap is defined for active members of the SD WAN link.
  - **Volume** - A volume ratio is set for each active member.
  - **Sessions** - A sessions ratio is set for each active member.
6. Go to **Network > Static Routes** and create a new default route. Set **Interface** to the SD-WAN link.
7. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add a security policy that allows users on the private network to access the Internet.

## Using a Virtual Wire Pair

A virtual wire pair consists of two interfaces that do not have IP addressing and are treated similar to a transparent mode VDOM. All traffic received by one interface in the virtual wire pair can only be forwarded out the other interface, provided that a virtual wire pair firewall policy allows this traffic. Traffic from other interfaces cannot be routed to the interfaces in a virtual wire pair.

Virtual wire pairs are useful for atypical topologies where MAC addresses do not behave normally. For example, port pairing can be used in a Direct Server Return (DSR) topology where the response MAC address pair may not match the request's MAC address pair.

Virtual wire pairing replaces the port pairing feature available in earlier firmware versions. Unlike port pairing, virtual wire pairing can be used for FortiGates in both NAT/Route and Transparent modes.

In the example configuration below, a virtual wire pair (consisting of port3 and port4) makes it easier to protect a web server that is behind a FortiGate operating as an Internal Segmentation Firewall (ISFW). Users on the internal network will access the web server through the ISFW over the virtual wire pair.

### Adding a virtual wire pair and virtual wire pair policy

Interfaces used in a virtual wire pair cannot be used to access the ISFW FortiGate. Before creating a virtual wire pair, make sure you have a different port configured to allow admin access using your preferred protocol.

1. Go to **Network > Interfaces** and select **Create New > Virtual Wire Pair**.
2. Select the interfaces to add to the virtual wire pair. These interfaces cannot be part of a switch, such as the default **lan/internal** interface.
3. (Optional) If desired, enable **Wildcard VLAN**.
4. Select **OK**.
5. Go to **Policy & Objects > IPv4 Virtual Wire Pair Policy**, select the virtual wire pair, and select **Create New**.
6. Select the direction that traffic is allowed to flow.
7. Configure the other firewall options as desired.
8. Select **OK**.
9. If necessary, create a second virtual wire pair policy to allow traffic to flow in the opposite direction.

---

If you have a USB-wan interface, it will not be included in the interface list when building a wired-pair.

---

## Results

Traffic can now flow through the FortiGate using the virtual wire pair. For more information on this feature, see the [Firewall](#) chapter.

## Using the GUI

This section presents an introduction to the FortiGate's graphical user interface (GUI), also called the web-based manager.

The following topics are included in this section:

- [Connecting to the GUI using a web browser](#)
- [Menus](#)
- [Dashboard](#)
- [Feature Visibility](#)
- [Tables](#)
- [Text Strings](#)

### Connecting to the GUI using a web browser

The graphical user interface is best displayed using a 1280 x 1024 resolution. Check the [FortiOS Release Notes](#) for information about browser compatibility.

---

In order to connect to the GUI using a web browser, an interface must be configured to allow administrative access over HTTPS or over both HTTPS and HTTP. By default, an interface has already been set up that allows HTTPS access, with the IP address 192.168.1.99.

Browse to <https://192.168.1.99> and enter your username and password. If you have not changed the admin account's password, use the default user name, `admin`, and leave the password field blank.

The GUI will now be displayed in your browser.

If you wish to use a different interface to access the GUI, do the following:

1. Go to **Network > Interfaces** and edit the interface you wish to use for access. Take note of its assigned IP address.
2. Beside **Administrative Access**, select **HTTPS**, and any other protocol you require. You can also select **HTTP**, although this is not recommended as the connection will be less secure.
3. Select **OK**.
4. Browse to the IP address using your chosen protocol.

#### Results

The GUI will now be displayed in your browser.

## Menus

If you believe your FortiGate model supports a menu that does not appear in the GUI as expected, go to **System > Feature Visibility** and ensure the feature is enabled. For more information, see ["Feature Visibility" on page 295](#).

The GUI contains the following main menus, which provide access to configuration options for most FortiOS features:

<b>Dashboard</b>	<p>The dashboard displays various widgets that display important system information and allow you to configure some system options.</p> <p>For more information, see <a href="#">"Dashboard" on page 292</a>.</p>
<b>Security Fabric</b>	<p>Access the physical topology, logical topology, audit, and settings features of the Fortinet Security Fabric.</p> <p>For more information, see the <a href="#">Fortinet Security Fabric</a> guide.</p>
<b>FortiView</b>	<p>A collection of dashboards and logs that give insight into network traffic, showing which users are creating the most traffic, what sort of traffic it is, when the traffic occurs, and what kind of threat the traffic may pose to the network.</p> <p>For more information, see the <a href="#">FortiView</a> handbook.</p>
<b>Network</b>	<p>Options for networking, including configuring system interfaces and routing options.</p> <p>For more information, see the <a href="#">Networking</a> handbook.</p>
<b>System</b>	<p>Configure system settings, such as administrators, FortiGuard, and certificates.</p> <p>For more information, see the <a href="#">System Administration</a> handbook.</p>
<b>Policy &amp; Objects</b>	<p>Configure firewall policies, protocol options, and supporting content for policies, including schedules, firewall addresses, and traffic shapers.</p> <p>For more information, see the <a href="#">Networking</a> handbook.</p>
<b>Security Profiles</b>	<p>Configure your FortiGate's security features, including AntiVirus, Web Filtering, and Application Control.</p> <p>For more information, see the <a href="#">Security Profiles</a> handbook.</p>
<b>VPN</b>	<p>Configure options for IPsec and SSL virtual private networks (VPNs).</p> <p>For more information, see the <a href="#">IPsec VPN</a> and <a href="#">SSL VPN</a> handbooks.</p>

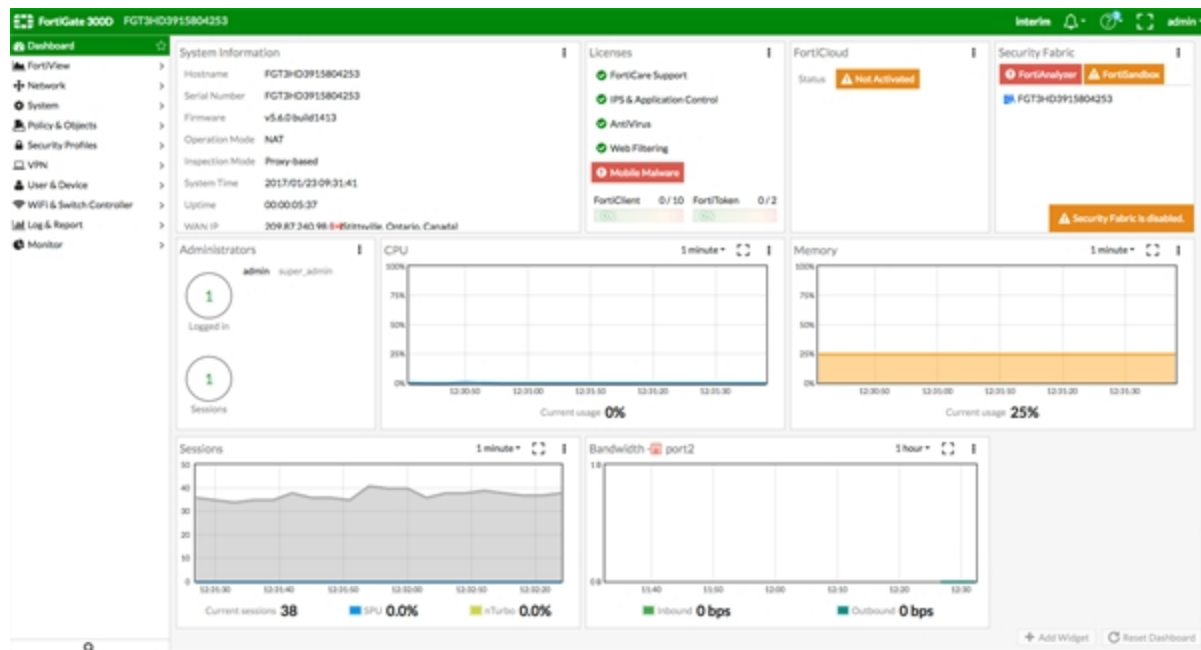

<b>User &amp; Device</b>	Configure user accounts, groups, and authentication methods, including external authentication and single sign-on (SSO).
<b>WiFi &amp; Switch Controller</b>	<p>Configure the unit to act as a wireless network controller, managing the wireless Access Point (AP) functionality of FortiWiFi and FortiAP units.</p> <p>On certain FortiGate models, this menu has additional features allowing for FortiSwitch units to be managed by the FortiGate.</p> <p>For more information, see the <a href="#">FortiWiFi and FortiAP Configuration Guide</a> handbook.</p>
<b>Log &amp; Report</b>	<p>Configure logging and alert email as well as reports.</p> <p>For more information, see the <a href="#">Logging and Reporting</a> handbook.</p>
<b>Monitor</b>	View a variety of monitors, including the Routing Monitor, VPN monitors for both IPsec and SSL, monitors relating to wireless networking, and more.

## Dashboard

The FortiOS **Dashboard** consists of a network operations center (NOC) view with a focus on alerts. Widgets are interactive; by clicking or hovering over most widgets, the user can get additional information or follow links to other pages.

The dashboard and its widgets include:

- Multiple dashboard support.
- VDOM and global dashboards.
- Widget resize control.
- Notifications on the top header bar.

The following widgets are displayed by default:

Widget	Description
<b>System Information</b>	The <b>System Information</b> widget lists information relevant to the FortiGate system, including Hostname, Serial Number, and Firmware.
<b>Security Fabric</b>	The <b>Security Fabric</b> widget is documented in the <a href="#">Fortinet Security Fabric</a> guide.
<b>CPU</b>	The real-time CPU usage is displayed for different time frames.

Widget	Description
<b>License Status</b>	<p>Hovering over the <b>Licenses</b> widget will display status information (and, where applicable, database information) on the licenses for <b>FortiCare Support, IPS &amp; Application Control, AntiVirus, Web Filtering, Mobile Malware</b>, and <b>FortiClient</b>.</p> <p>Clicking in the <b>Licenses</b> widget will provide you with links to other pages, such as <b>System &gt; FortiGuard</b> or contract renewal pages.</p>
<b>FortiCloud</b>	This widget displays FortiCloud status and provides a link to activate FortiCloud.
<b>Administrators</b>	This widget allows you to view which administrators are logged in and how many sessions are active. The link directs you to a page displaying active administrator sessions.
<b>Memory</b>	Real-time memory usage is displayed for different time frames. Hovering over any point on the graph displays percentage of memory used along with a timestamp.
<b>Sessions</b>	<p>Hovering over the <b>Sessions</b> widget allows you to view memory usage data over time. Click on the down-arrow to change the timeframe displayed.</p> <p><b>SPU</b> (Security Processing Unit) percentage is displayed if your FortiGate includes an SPU. Likewise, <b>nTurbo</b> percentage is displayed if supported by your FortiGate. See the <a href="#">Hardware Acceleration</a> chapter for details.</p>
<b>Bandwidth</b>	<p>Hover over the <b>Bandwidth</b> widget to display bandwidth usage data over time. Click on the down-arrow to change the timeframe displayed.</p> <p>Bandwidth is displayed for both incoming and outgoing traffic.</p>
<b>Virtual Machine</b>	<p>The VM widget (shown by default in the dashboard of a FortiOS VM device) includes:</p> <ul style="list-style-type: none"> <li>• License status and type</li> <li>• CPU allocation usage</li> <li>• License RAM usage</li> <li>• VMX license information (if the VM supports VMX)</li> </ul> <p>If the VM license specifies 'unlimited' the progress bar is blank. If the VM is in evaluation mode, it is yellow (warning style) and the dashboard show evaluation days used.</p>

The following optional widgets are also available:

- FortiView
- Host Scan Summary
- Vulnerabilities Summary
- Botnet Activity
- HA Status
- Log Rate

- Session Rate
- Security Fabric Score
- Advanced Threat Protection Statistics
- Interface Bandwidth

## Feature Visibility

Feature Visibility is used to control which features are visible in the GUI. This allows you to hide features that are not being used. Some features are also disabled by default and must be enabled in order to configure them through the GUI.

Feature Visibility only alters the visibility of these features, rather than their functionality. For example, disabling web filtering on the **Feature Visibility** page does not remove web filtering from the FortiGate, but removes the option of configuring web filtering from the GUI. Configuration options will still be available using the CLI.

### Enabling/disabling features

Feature Visibility can be found at **System > Feature Visibility**. Ensure that all features you wish to configure in the GUI are turned on, and that features you wish to hide are turned off. When you have finished, select **Apply**.

### Security Features Presets

The main Security Features can be toggled individually, however six system presets (or **Feature Sets**) are available:

- **NGFW** should be chosen for networks that require application control and protection from external attacks.
- **ATP** should be chosen for networks that require protection from viruses and other external threats.
- **WF** should be chosen for networks that require web filtering.
- **NGFW + ATP** should be chosen for networks that require protection from external threats and attacks.
- **UTM** should be chosen for networks that require protection from external threats and wish to use security features that control network usage. This is the default setting.
- **Custom** should be chosen for networks that require customization of available features (including the ability to select all features).

## Tables

Many of the GUI pages contain tables of information that you can filter to display specific information. Administrators with read and write access can define the filters.

### Navigation

Some tables contain information and lists that span multiple pages. Navigation controls appear at the bottom of the page.

### Filters

Filters are used to locate a specific set of information or content within multiple pages. These are especially useful in locating specific log entries. The specific filtering options vary, depending on the type of information in the log.

To create a filter, select **Add Filter** at the top of the page. A list of the available fields for filtering will be shown.

### Column settings

Column settings are used to select the types of information displayed on a certain page. Some pages have large amounts of information available and not all content can be displayed on a single screen. Some pages may even contain content that is irrelevant to you. Using column settings, you can choose to display only relevant content.

To view configure column settings, right-click the header of a column and select the columns you wish to view and de-select any you wish to hide. After you have finished making your selections, click **Apply** (you may need to scroll down the list to do so).

Any changes that you make to the column settings are stored in the unit's configuration. To return columns to the default state for any given page, right-click any header and select **Reset Table**.

### Copying objects

In tables containing configuration objects, such as the policy table found at **Policy & Objects > IPv4 Policy**, you have the option to copy an object. This allows you to create a copy of that object, which you can then configure as needed. You can also reverse copy a policy to change the direction of the traffic impacted by that policy.

To copy an object:

1. Select that object, then right-click to make a menu appear and select the **Copy** option.
2. Right-click the row in the table that is either above or below where you want the copied object to be placed, select the **Paste** option and indicate **Above** or **Below**.

Reverse cloning works much the same way. Instead of selecting **Copy**, you will select **Clone Reverse**.

Once the policy is copied, you must give it a name, configure as needed, and enable it.

### Editing objects

Some tables allow you to edit parts of the configuration directly on the table itself. For example, security features can be added to an existing firewall policy from the policy list by clicking on the plus sign in the **Security Profiles** column and selecting the desired profiles.

If this option is not immediately available, check to see that the column is not hidden (see [Column settings](#)). Otherwise, you must select the object and open the policy by selecting the **Edit** option found at the top of the page.

## Text Strings

The configuration of a FortiGate is stored in the FortiOS configuration database. To change the configuration, you can use the GUI or CLI to add, delete, or change configuration settings. These changes are stored in the database as you make them. Individual settings in the configuration database can be text strings, numeric values, selections from a list of allowed options, or on/off (enable/disable) settings.

### Entering text strings (names)

Text strings are used to name entities in the configuration. For example, the name of a firewall address, the name of an administrative user, and so on. You can enter any character in a FortiGate configuration text string, except the following characters that present Cross-Site Scripting (XSS) vulnerabilities:

- “ (double quote)
- & (ampersand)
- ' (single quote)
- < (less than)
- > (greater than)

Most GUI text string fields make it easy to add an acceptable number of characters and prevent you from adding the XSS vulnerability characters.

There is a different character limitation for VDOM names and hostnames. The only valid characters are numbers (0-9), letters (a-z, A-Z), and special characters - (dash) and \_ (underscore).

From the CLI, you can also use the `tree` command to view the number of characters that are allowed in a name field. For example, firewall address names can contain up to 64 characters. When you add a firewall address to the GUI, you are limited to entering 64 characters in the firewall address name field. From the CLI you can enter the following `tree` command to confirm that the firewall address `name` field allows 64 characters.

```
config firewall address
  tree
  -- [address] --*name (64)
  |- uuid
  |- subnet
  |- type
  |- start-ip
  |- end-ip
  |- fqdn (256)
  |- country (3)
  |- cache-ttl (0,86400)
  |- wildcard
  |- comment
  |- visibility
  |- associated-interface (36)
  |- color (0,32)
  |- [tags] --*name (65)
  +- allow-routing
```

The `tree` command output also shows the number of characters allowed for other firewall address name settings. For example, the fully qualified domain name (`fqdn`) field can contain up to 256 characters.

## Entering numeric values

Numeric values set various sizes, rates, addresses, and other numeric values (e.g. a static routing priority of 10, a port number of 8080, an IP address of 10.10.10.1). Numeric values can be entered as a series of digits without spaces or commas (for example, 10 or 64400), in dotted decimal format (for example the IP address 10.10.10.1) or, as in the case of MAC or IPv6 addresses, separated by colons (e.g. the MAC address 00:09:0F:B7:37:00). Most numeric values are standard base-10 numbers, but some fields - again, such as MAC addresses - require hexadecimal numbers.

Most GUI numeric value fields make it easy to add the acceptable number of digits within the allowed range. CLI help text includes information about allowed numeric value ranges. Both the GUI and the CLI prevent you from entering invalid numbers.

## Using the CLI

The command line interface (CLI) is an alternative configuration tool to the GUI or web-based manager. While the configuration of the GUI uses a point-and-click method, the CLI requires typing commands or uploading batches of commands from a text file, like a configuration script.

This section explains common CLI tasks that an administrator does on a regular basis and includes the topics:

- [Connecting to the CLI](#)
- [Command syntax](#)
- [Sub-commands](#)
- [Permissions](#)
- [Tips](#)

## Connecting to the CLI

You can access the CLI in three ways:

- [Locally with a console cable](#) — Connect your computer directly to the FortiGate unit's console port. Local access is required in some cases:
  - If you are installing your FortiGate unit for the first time and it is not yet configured to connect to your network, you may only be able to connect to the CLI using a local serial console connection, unless you reconfigure your computer's network settings for a peer connection.
  - Restoring the firmware utilizes a boot interrupt. Network access to the CLI is not available until after the boot process has completed, making local CLI access the only viable option.
- [Through the network](#) — Connect your computer through any network attached to one of the FortiGate unit's network ports. The network interface must have enabled Telnet or SSH administrative access if you connect using an SSH/Telnet client, or HTTP/HTTPS administrative access if you connect by accessing the **CLI Console** in the GUI. The CLI console can be accessed from the upper-right hand corner of the screen and appears as a slide-out window.
- [Locally with FortiExplorer for iOS](#) — Use the FortiExplorer app on your iOS device to configure, manage, and monitor your FortiGate.

### Connecting to the CLI using a local console

Local console connections to the CLI are formed by directly connecting your management computer or console to the FortiGate unit, using its DB-9 or RJ-45 console port. To connect to the local console you need:

- A computer with an available serial communications (COM) port.
- The RJ-45-to-DB-9 or null modem cable included in your FortiGate package.
- Terminal emulation software such as HyperTerminal for Microsoft Windows.

The following procedure describes the connection using Microsoft HyperTerminal software; steps may vary with other terminal emulators.

#### To connect to the CLI using a local serial console connection

1. Using the null modem or RJ-45-to-DB-9 cable, connect the FortiGate unit's console port to the serial communications (COM) port on your management computer.

2. On your management computer, start HyperTerminal.
3. For the **Connection Description**, enter a **Name** for the connection, and select **OK**.
4. On the **Connect using** drop-down, select the communications (COM) port on your management computer you are using to connect to the FortiGate unit.
5. Select **OK**.
6. Select the following **Port** settings and select **OK**.

<b>Bits per second</b>	9600
<b>Data bits</b>	8
<b>Parity</b>	None
<b>Stop bits</b>	1
<b>Flow control</b>	None

7. Press **Enter** or **Return** on your keyboard to connect to the CLI.
8. Type a valid administrator account name (such as `admin`) and press **Enter**.
9. Type the password for that administrator account and press **Enter**. (In its default state, there is no password for the `admin` account.)

The CLI displays the following text:

```
Welcome!
Type ? to list available commands.
```

You can now enter CLI commands, including configuring access to the CLI through SSH or Telnet.

## Enabling access to the CLI through the network (SSH or Telnet)

SSH or Telnet access to the CLI is accomplished by connecting your computer to the FortiGate unit using one of its RJ-45 network ports. You can either connect directly, using a peer connection between the two, or through any intermediary network.

If you do not want to use an SSH/Telnet client and you have access to the web-based manager, you can alternatively access the CLI through the network using the **CLI Console** widget in the web-based manager.

You must enable SSH and/or Telnet on the network interface associated with that physical network port. If your computer is not connected directly or through a switch, you must also configure the FortiGate unit with a static route to a router that can forward packets from the FortiGate unit to your computer. You can do this using either a local console connection or the web-based manager.

## Requirements

- A computer with an available serial communications (COM) port and RJ-45 port
- Terminal emulation software such as HyperTerminal for Microsoft Windows
- The RJ-45-to-DB-9 or null modem cable included in your FortiGate package
- A network cable
- Prior configuration of the operating mode, network interface, and static route.

### To enable SSH or Telnet access to the CLI using a local console connection

1. Using the network cable, connect the FortiGate unit's network port either directly to your computer's network port, or to a network through which your computer can reach the FortiGate unit.
2. Note the number of the physical network port.
3. Using a local console connection, connect and log into the CLI.
4. Enter the following command:

```
config system interface
  edit <interface_str>
    set allowaccess <protocols_list>
  end
```

where:

- <interface\_str> is the name of the network interface associated with the physical network port and containing its number, such as `port1`.
- <protocols\_list> is the complete, space-delimited list of permitted administrative access protocols, such as `https ssh telnet`.

For example, to exclude HTTP, HTTPS, SNMP, and PING, and allow only SSH and Telnet administrative access on `port1`, enter the following:

```
config system interface
  edit port1
    set allowaccess ssh telnet
  end
```

5. To confirm the configuration, enter the command to display the network interface's settings.

```
show system interface <interface_str>
```

The CLI displays the settings, including the allowed administrative access protocols, for the network interfaces.

### Connecting to the CLI using SSH

Once the FortiGate unit is configured to accept SSH connections, you can use an SSH client on your management computer to connect to the CLI.

Secure Shell (SSH) provides both secure authentication and secure communications to the CLI. FortiGate units support 3DES and Blowfish encryption algorithms for SSH.

Before you can connect to the CLI using SSH, you must first configure a network interface to accept SSH connections. The following procedure uses PuTTY. Steps may vary with other SSH clients.

### To connect to the CLI using SSH

1. On your management computer, start an SSH client.
2. In **Host Name (or IP address)**, enter the IP address of a network interface on which you have enabled SSH administrative access.
3. Set a **Port** of 22.
4. For the **Connection type**, select **SSH**.
5. Select **Open**.

The SSH client connects to the FortiGate unit.

The SSH client may display a warning if this is the first time you are connecting to the FortiGate unit and its SSH key is not yet recognized by your SSH client, or if you have previously connected to the FortiGate unit but used a different IP address or SSH key. This is normal if your management computer is directly connected to the FortiGate unit with no network hosts between them.

6. Click **Yes** to verify the fingerprint and accept the FortiGate unit's SSH key. You will not be able to log in until you have accepted the key.
7. The CLI displays a login prompt.
8. Type a valid administrator account name (such as `admin`) and press **Enter**.
9. Type the password for this administrator account and press **Enter**.  
The FortiGate unit displays a command prompt (its hostname followed by a #). You can now enter CLI commands.

If three incorrect login or password attempts occur in a row, you will be disconnected. If this occurs, wait one minute, then reconnect to attempt the login again.

---

### Connecting to the CLI using Telnet

Once the FortiGate unit is configured to accept Telnet connections, you can use a Telnet client on your management computer to connect to the CLI.

Telnet is not a secure access method. SSH should be used to access the CLI from the Internet or any other untrusted network.

---

Before you can connect to the CLI using Telnet, you must first configure a network interface to accept Telnet connections.

### To connect to the CLI using Telnet

1. On your management computer, start a Telnet client.
2. Connect to a FortiGate network interface on which you have enabled Telnet.
3. Type a valid administrator account name (such as `admin`) and press **Enter**.
4. Type the password for this administrator account and press **Enter**.  
The FortiGate unit displays a command prompt (its hostname followed by a #). You can now enter CLI commands.

If three incorrect login or password attempts occur in a row, you will be disconnected. If this occurs, wait one minute, then reconnect to attempt the login again.

---

## CLI-only features

As you can see in the [Feature / Platform Matrix](#), the entry level models have a number of features that are only available using the CLI, rather than appearing in the GUI.

You can open the CLI console so that it automatically opens to the object you wish to configure. For example, to edit a firewall policy, right-click on the policy in the policy list (**Policy & Objects > IPv4 Policy**) and select **Edit in CLI**. The CLI console will appear, with the commands to access this part of the configuration added automatically.

Once you have access to the CLI, you can enter instructions for specific tasks that can be found throughout the FortiOS Handbook. Options are also available at the top of the CLI Console to **Clear console**, **Download**, and **Copy to clipboard**.

Refer to the [CLI Reference](#) for a list of the available commands.

## Command syntax

When entering a command, the CLI console requires that you use valid syntax and conform to expected input constraints. It will reject invalid commands.

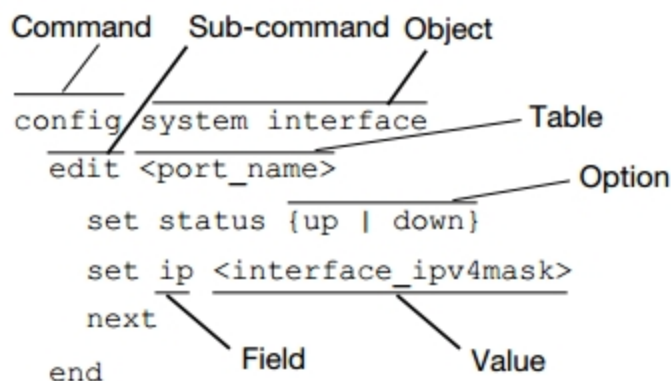

Fortinet documentation uses the conventions below to describe valid command syntax.

### Terminology

Each command line consists of a command word that is usually followed by configuration data or other specific item that the command uses or affects.

To describe the function of each word in the command line, especially if that nature has changed between firmware versions, Fortinet uses terms with the following definitions.

#### Command syntax terminology

- **Command** — A word that begins the command line and indicates an action that the FortiGate unit should perform on a part of the configuration or host on the network, such as `config` or `execute`. Together with other words, such as fields or values, that end when you press the **Enter** key, it forms a command line. Exceptions include multi-line command lines, which can be entered using an escape sequence. Valid command lines must be unambiguous if abbreviated. Optional words or other command line permutations are indicated by syntax notation.
- **Sub-command** — A kind of command that is available only when nested within the scope of another command. After entering a command, its applicable sub-commands are available to you until you exit the scope of the command, or until you descend an additional level into another sub-command. Indentation is used to indicate levels of nested commands. Not all top-level commands have sub-commands. Available sub-commands vary by their containing scope.
- **Object** — A part of the configuration that contains tables and /or fields. Valid command lines must be specific enough to indicate an individual object.
- **Table** — A set of fields that is one of possibly multiple similar sets which each have a name or number, such as an administrator account, policy, or network interface. These named or numbered sets are sometimes referenced by other parts of the configuration that use them.
- **Field** — The name of a setting, such as `ip` or `hostname`. Fields in some tables must be configured with values. Failure to configure a required field will result in an invalid object configuration error message, and the FortiGate unit will discard the invalid table.

- **Value** — A number, letter, IP address, or other type of input that is usually your configuration setting held by a field. Some commands, however, require multiple input values which may not be named but are simply entered in sequential order in the same command line. Valid input types are indicated by constraint notation.
- **Option** — A kind of value that must be one or more words from of a fixed set of options.

## Indentation

Indentation indicates levels of nested commands, which indicate what other sub-commands are available from within the scope. For example, the `edit` sub-command is available only within a command that affects tables, and the `next` sub-command is available only from within the `edit` sub-command:

```
config system interface
  edit port1
    set status up
  next
end
```

## Notation

Brackets, braces, and pipes are used to denote valid permutations of the syntax. Constraint notations, such as `<address_ipv4>`, indicate which data types or string patterns are acceptable value input.

### Command syntax notation

Convention	Description
<b>Square brackets</b> [ ]	<p>An optional word or series of words. For example:</p> <pre>[verbose {1   2   3}]</pre> <p>indicates that you may either omit or type both the <code>verbose</code> word and its accompanying option, such as <code>verbose 3</code>.</p>
<b>Curly braces</b> { }	<p>A word or series of words that is constrained to a set of options delimited by either vertical bars or spaces. You must enter at least one of the options, unless the set of options is surrounded by square brackets [ ].</p>
<b>Options delimited by vertical bars</b>	<p>Mutually exclusive options. For example:</p> <pre>{enable   disable}</pre> <p>indicates that you must enter either <code>enable</code> or <code>disable</code>, but must not enter both.</p>

Convention	Description
<b>Angle brackets</b> < >	<p>A word constrained by data type. The angled brackets contain a descriptive name followed by an underscore ( _ ) and suffix that indicates the valid data type. For example, &lt;retries_int&gt;, indicates that you should enter a number of retries as an integer.</p> <p>Data types include:</p> <ul style="list-style-type: none"> <li>• &lt;xxx_name&gt;: A name referring to another part of the configuration, such as <code>policy_A</code>.</li> <li>• &lt;xxx_index&gt;: An index number referring to another part of the configuration, such as 0 for the first static route.</li> <li>• &lt;xxx_pattern&gt;: A regular expression or word with wild cards that matches possible variations, such as <code>*@example.com</code> to match all email addresses ending in <code>@example.com</code>.</li> <li>• &lt;xxx_fqdn&gt;: A fully qualified domain name (FQDN), such as <code>mail.example.com</code>.</li> <li>• &lt;xxx_email&gt;: An email address, such as <code>admin@example.com</code>.</li> <li>• &lt;xxx_ipv4&gt;: An IPv4 address, such as <code>192.168.1.99</code>.</li> <li>• &lt;xxx_v4mask&gt;: A dotted decimal IPv4 netmask, such as <code>255.255.255.0</code>.</li> <li>• &lt;xxx_ipv4mask&gt;: A dotted decimal IPv4 address and netmask separated by a space, such as <code>192.168.1.99 255.255.255.0</code>.</li> <li>• &lt;xxx_ipv4/mask&gt;: A dotted decimal IPv4 address and CIDR-notation netmask separated by a slash, such as <code>192.168.1.1/24</code></li> <li>• &lt;xxx_ipv4range&gt; : A hyphen ( - )-delimited inclusive range of IPv4 addresses, such as <code>192.168.1.1-192.168.1.255</code>.</li> <li>• &lt;xxx_ipv6&gt;: A colon ( : )-delimited hexadecimal IPv6 address, such as <code>3f2e:6a8b:78a3:0d82:1725:6a2f:0370:6234</code>.</li> <li>• &lt;xxx_v6mask&gt;: An IPv6 netmask, such as <code>/96</code>.</li> <li>• &lt;xxx_ipv6mask&gt;: A dotted decimal IPv6 address and netmask separated by a space.</li> <li>• &lt;xxx_str&gt;: A string of characters that is not another data type, such as <code>P@ssw0rd</code>. Strings containing spaces or special characters must be surrounded in quotes or use escape sequences.</li> <li>• &lt;xxx_int&gt;: An integer number that is <b>not</b> another data type, such as 15 for the number of minutes.</li> </ul>
<b>Options delimited by spaces</b>	<p>Non-mutually exclusive options. For example:</p> <pre>{http https ping snmp ssh telnet}</pre> <p>indicates that you may enter all or a subset of those options, in any order, in a space-delimited list, such as:</p> <pre>ping https ssh</pre>

## Sub-commands

Each command line consists of a command word that is usually followed by configuration data or other specific item that the command uses or affects:

```
get system admin
```

Sub-commands are available from within the scope of some commands. When you enter a sub-command level, the command prompt changes to indicate the name of the current command scope. For example, after entering:

```
config system admin
```

the command prompt becomes:

```
(admin) #
```

Applicable sub-commands are available to you until you exit the scope of the command, or until you descend an additional level into another sub-command.

For example, the `edit` sub-command is available only within a command that affects tables; the `next` sub-command is available only from within the `edit` sub-command:

```
config system interface
  edit port1
    set status up
  next
end
```

Sub-command scope is indicated by indentation.

Available sub-commands vary by command. From a command prompt within `config`, two types of sub-commands might become available:

- commands affecting fields
- commands affecting tables

### Commands for tables

#### **clone <table>**

Clone (or make a copy of) a table from the current object.

For example, in `config firewall policy`, you could enter the following command to clone security policy 27 to create security policy 30:

```
clone 27 to 30
```

In `config antivirus profile`, you could enter the following command to clone an antivirus profile named `av_pro_1` to create a new antivirus profile named `av_pro_2`:

```
clone av_pro_1 to av_pro_2
```

`clone` may not be available for all tables.

**delete <table>**

Remove a table from the current object.

For example, in `config system admin`, you could delete an administrator account named `newadmin` by typing `delete newadmin` and pressing Enter. This deletes `newadmin` and all its fields, such as `newadmin's first-name` and `email-address`.

`delete` is only available within objects containing tables.

**edit <table>**

Create or edit a table in the current object.

For example, in `config system admin`:

- edit the settings for the default `admin` administrator account by typing `edit admin`.
- add a new administrator account with the name `newadmin` and edit `newadmin's` settings by typing `edit newadmin`.

`edit` is an interactive sub-command: further sub-commands are available from within `edit`.

`edit` changes the prompt to reflect the table you are currently editing.

`edit` is only available within objects containing tables.

In objects such as security policies, `<table>` is a sequence number. To create a new entry without the risk of overwriting an existing one, enter `edit 0`. The CLI initially confirms the creation of entry 0, but assigns the next unused number after you finish editing and enter `end`.

**end**

Save the changes to the current object and exit the `config` command. This returns you to the top-level command prompt.

**get**

List the configuration of the current object or table.

- In objects, `get` lists the table names (if present), or fields and their values.
- In a table, `get` lists the fields and their values.

For more information on `get` commands, see the [CLI Reference](#).

**purge**

Remove all tables in the current object.

For example, in `config user local`, you could type `get` to see the list of user names, then type `purge` and then `y` to confirm that you want to delete all users.

`purge` is only available for objects containing tables.

**Caution:** Back up the FortiGate before performing a `purge`. `purge` cannot be undone. To restore purged tables, the configuration must be restored from a backup.

**Caution:** Do not purge `system interface` or `system admin` tables. `purge` does not provide default tables. This can result in being unable to connect or log in, requiring the FortiGate unit to be formatted and restored.

**rename <table> to <table>**

Rename a table.

For example, in `config system admin`, you could rename `admin3` to `fwadmin` by typing `rename admin3 to fwadmin`.

`rename` is only available within objects containing tables.

**show**

Display changes to the default configuration. Changes are listed in the form of configuration commands.

**Example of table commands**

From within the `system admin` object, you might enter:

```
edit admin_1
```

The CLI acknowledges the new table, and changes the command prompt to show that you are now within the `admin_1` table:

```
new entry 'admin_1' added
(admin_1)#
```

**Commands for fields**

<b>abort</b>	Exit both the <code>edit</code> and/or <code>config</code> commands without saving the fields.
<b>append</b>	Add an option to an existing list.
<b>end</b>	Save the changes made to the current table or object fields, and exit the <code>config</code> command (to exit without saving, use <code>abort</code> instead).
<b>get</b>	<p>List the configuration of the current object or table.</p> <ul style="list-style-type: none"> <li>In objects, <code>get</code> lists the table names (if present), or fields and their values.</li> <li>In a table, <code>get</code> lists the fields and their values.</li> </ul>

<b>move</b>	Move an object within a list, when list order is important. For example, rearranging security policies within the policy list.
<b>next</b>	<p>Save the changes you have made in the current table's fields, and exit the <code>edit</code> command to the object prompt (to save and exit completely to the root prompt, use <code>end</code> instead).</p> <p><code>next</code> is useful when you want to create or edit several tables in the same object, without leaving and re-entering the <code>config</code> command each time.</p> <p><code>next</code> is only available from a table prompt; it is not available from an object prompt.</p>
<b>select</b>	<p>Clear all options except for those specified.</p> <p>For example, if a group contains members A, B, C, and D and you remove all users except for B, use the command <code>select member B</code>.</p>
<b>set &lt;field&gt; &lt;value&gt;</b>	<p>Set a field's value.</p> <p>For example, in <code>config system admin</code>, after typing <code>edit admin</code>, you could type <code>set password newpass</code> to change the password of the <code>admin</code> administrator to <code>newpass</code>.</p> <p><b>Note:</b> When using <code>set</code> to change a field containing a space-delimited list, type the whole new list. For example, <code>set &lt;field&gt; &lt;new-value&gt;</code> will replace the list with the <code>&lt;new-value&gt;</code> rather than appending <code>&lt;new-value&gt;</code> to the list.</p>
<b>show</b>	Display changes to the default configuration. Changes are listed in the form of configuration commands.
<b>unselect</b>	Remove an option from an existing list.
<b>unset &lt;field&gt;</b>	<p>Reset the table or object's fields to default values.</p> <p>For example, in <code>config system admin</code>, after typing <code>edit admin</code>, typing <code>unset password</code> resets the password of the <code>admin</code> administrator account to the default (in this case, no password).</p>

### Example of field commands

From within the `admin_1` table, you might enter:

```
set password my1stExamplePassword
```

to assign the value `my1stExamplePassword` to the `password` field. You might then enter the `next` command to save the changes and edit the next administrator's table.

## Permissions

Access profiles control which CLI commands an administrator account can access. Access profiles assign either read, write, or no access to each area of FortiOS. To view configurations, you must have read access. To make changes, you must have write access. So, depending on the account used to log in to the FortiGate, you may not have complete access to all CLI commands. For complete access to all commands, you must log in with an administrator account that has the `super_admin` access profile. By default the `admin` administrator account has the `super_admin` access profile.

Administrator accounts, with the `super_admin` access profile are similar to a root administrator account that always has full permission to view and change all FortiGate configuration options, including viewing and changing all other administrator accounts and including changing other administrator account passwords.

### Increasing the security of administrator accounts

Set strong passwords for all administrator accounts (including the `admin` account) and change passwords regularly.

For more information about increasing the security of administrator accounts, see:

- [Hardening your FortiGate](#)

## Tips

Basic features and characteristics of the CLI environment provide support and ease of use for many CLI tasks.

### Help

To display brief help during command entry, press the question mark (?) key.

- Press the question mark (?) key at the command prompt to display a list of the commands available and a description of each command.
- Type a word or part of a word, then press the question mark (?) key to display a list of valid word completions or subsequent words, and to display a description of each.

### Shortcuts and key commands

Keys	Action
?	List valid word completions or subsequent words.  If multiple words could complete your entry, display all possible completions with helpful descriptions of each.
Tab	Complete the word with the next available match.  Press the <b>Tab</b> key multiple times to cycle through available matches.
Up arrow, or Ctrl + P	Recall the previous command.  Command memory is limited to the current session.
Down arrow, or Ctrl + N	Recall the next command.
Left or Right arrow	Move the cursor left or right within the command line.
Ctrl + A	Move the cursor to the beginning of the command line.
Ctrl + E	Move the cursor to the end of the command line.
Ctrl + B	Move the cursor backwards one word.
Ctrl + F	Move the cursor forwards one word.
Ctrl + D	Delete the current character.

Keys	Action
<b>Ctrl + C</b>	<p>Abort current interactive commands, such as when entering multiple lines.</p> <p>If you are not currently within an interactive command such as <code>config</code> or <code>edit</code>, this closes the CLI connection.</p>
<b>\ then Enter</b>	<p>Continue typing a command on the next line for a multi-line command.</p> <p>For each line that you want to continue, terminate it with a backslash ( \ ). To complete the command line, terminate it by pressing the <b>spacebar</b> and then the <b>Enter</b> key, without an immediately preceding backslash.</p>

## Command abbreviation

You can abbreviate words in the command line to their smallest number of non-ambiguous characters.

For example, the command `get system status` could be abbreviated to `g sy stat`.

## Adding and removing options from lists

When adding options to a list, such as a user group, using the `set` command will remove the previous configuration. For example, if you wish to add user D to a user group that already contains members A, B, and C, the command would need to be `set member A B C D`. If only `set member D` was used, then all former members would be removed from the group.

However, there are additional commands which can be used instead of `set` for changing options in a list.

### Additional commands for lists

<b>append</b>	<p>Add an option to an existing list.</p> <p>For example, <code>append member</code> would add user D to a user group while all previous group members are retained</p>
<b>select</b>	<p>Clear all options except for those specified.</p> <p>For example, if a group contains members A, B, C, and D and you remove all users except for B, use the command <code>select member B</code>.</p>
<b>unselect</b>	<p>Remove an option from an existing list.</p> <p>For example, <code>unselect member A</code> would remove member A from a group while all previous group members are retained.</p>

## Environment variables

The CLI supports the following environment variables. Variable names are case-sensitive.

## Environment variables

<b>\$USERFROM</b>	The management access type ( <code>ssh</code> , <code>telnet</code> , <code>jsconsole</code> for the <b>CLI Console</b> widget in the web-based manager, and so on) and the IP address of the administrator that configured the item.
<b>\$USERNAME</b>	The account name of the administrator that configured the item.
<b>\$SerialNum</b>	The serial number of the FortiGate unit.

For example, the FortiGate unit's host name can be set to its serial number:

```
config system global
    set hostname $SerialNum
end
```

## Special characters

The following special characters, also known as reserved characters, are not permitted in most CLI fields:

<                      >                      (                      )                      #                      '                      “

You may be able to enter special characters as part of a string's value by using a special command, enclosing it in quotes, or preceding it with an escape sequence — in this case, a backslash ( \ ) character.

In other cases, different keystrokes are required to input a special character. If you need to enter **?** as part of config, you first need to input **CTRL-V**. If you enter **?** without first using **CTRL-V**, the question mark has a different meaning in the CLI; it will show available command options in that section.

For example, if you enter **?** without **CTRL-V**:

```
edit "*.xe
token line: Unmatched double quote.
```

If you enter **?** with **CTRL-V**:

```
edit "*.xe?"
new entry '*.xe?' added
```

## Entering special characters

Character	Keys
<b>?</b>	Ctrl + V then <b>?</b>
<b>Tab</b>	Ctrl + V then Tab

Character	Keys
<b>Space</b>  (to be interpreted as part of a string value, not to end the string)	Enclose the string in quotation marks: "Security Administrator".  Enclose the string in single quotes: 'Security Administrator'.  Precede the space with a backslash: Security\ Administrator.
'	\'
(to be interpreted as part of a string value, not to end the string)	
"	\"
(to be interpreted as part of a string value, not to end the string)	
\	\\

## Using grep to filter get and show command output

In many cases, the `get` and `show` (and `diagnose`) commands may produce a large amount of output. If you are looking for specific information in a large `get` or `show` command output, you can use the `grep` command to filter the output to only display what you are looking for. The `grep` command is based on the standard UNIX `grep`, used for searching text output based on regular expressions.

Use the following command to display the MAC address of the FortiGate unit internal interface:

```
get hardware nic internal | grep Current_HWaddr
Current_HWaddr           00:09:0f:cb:c2:75
```

Use the following command to display all TCP sessions in the session list and include the session list line number in the output:

```
get system session list | grep -n tcp
```

Use the following command to display all lines in HTTP replacement message commands that contain URL (upper or lower case):

```
show system replacemsg http | grep -i url
```

There are three additional options that can be applied to `grep`:

```
-A <num> After
-B <num> Before
-C <num> Context
```

The option `-f` is also available to support contextual output, in order to show the complete configuration. The following example shows the difference in output when `-f` option is used versus when it is not.

**Using -f:**

```
show | grep -f ldap-group1
config user group
  edit "ldap-group1"
    set member "pc40-LDAP"
  next
end
config firewall policy
  edit 2
    set srcintf "port31"
    set dstintf "port32"
    set srcaddr "all"
    set action accept
    set identity-based enable
    set nat enable
    config identity-based-policy
      edit 1
        set schedule "always"
        set groups "ldap-group1"
        set dstaddr "all"
        set service "ALL"
      next
    end
  next
end
```

**Without using -f:**

```
show | grep ldap-group1
edit "ldap-group1"
  set groups "ldap-group1"
```

**Language support and regular expressions**

Characters such as ñ, é, symbols, and ideographs are sometimes acceptable input. Support varies by the nature of the item being configured. CLI commands, objects, field names, and options must use their exact ASCII characters, but some items with arbitrary names or values may be input using your language of choice. To use other languages in those cases, you must use the correct encoding.

Input is stored using Unicode UTF-8 encoding but is not normalized from other encodings into UTF-8 before it is stored. If your input method encodes some characters differently than in UTF-8, your configured items may not display or operate as expected.

Regular expressions are especially impacted. Matching uses the UTF-8 character values. If you enter a regular expression using another encoding, or if an HTTP client sends a request in an encoding other than UTF-8, matches may not be what you expect.

For example, with Shift-JIS, backslashes ( \ ) could be inadvertently interpreted as the symbol for the Japanese yen ( ¥ ) and vice versa. A regular expression intended to match HTTP requests containing money values with a yen symbol therefore may not work if the symbol is entered using the wrong encoding.

For best results, you should:

- use UTF-8 encoding, or
- use only the characters whose numerically encoded values are the same in UTF-8, such as the US-ASCII characters that are also encoded using the same values in ISO 8859-1, Windows code page 1252, Shift-JIS and other encodings, or
- for regular expressions that must match HTTP requests, use the same encoding as your HTTP clients.

HTTP clients may send requests in encodings other than UTF-8. Encodings usually vary by the client's operating system or input language. If you cannot predict the client's encoding, you may only be able to match any parts of the request that are in English, because regardless of the encoding, the values for English characters tend to be encoded identically. For example, English words may be legible regardless of interpreting a web page as either ISO 8859-1 or as GB2312, whereas simplified Chinese characters might only be legible if the page is interpreted as GB2312.

If you configure your FortiGate unit using other encodings, you may need to switch language settings on your management computer, including for your web browser or Telnet/SSH client. For instructions on how to configure your management computer's operating system language, locale, or input method, see its documentation.

If you choose to configure parts of the FortiGate unit using non-ASCII characters, verify that all systems interacting with the FortiGate unit also support the same encodings. You should also use the same encoding throughout the configuration if possible in order to avoid needing to switch the language settings of the web-based manager and your web browser or Telnet/SSH client while you work.

Similarly to input, your web browser or CLI client should normally interpret display output as encoded using UTF-8. If it does not, your configured items may not display correctly in the GUI or CLI. Exceptions include items such as regular expressions that you may have configured using other encodings in order to match the encoding of HTTP requests that the FortiGate unit receives.

#### To enter non-ASCII characters in the CLI Console:

1. On your management computer, start your web browser and go to the URL for the FortiGate unit's GUI.
2. Configure your web browser to interpret the page as UTF-8 encoded.
3. Log in to the FortiGate unit.
4. Open the CLI Console from the upper right-hand corner.
5. In the title bar of the **CLI Console** widget, click **Edit** (the pencil icon).
6. Enable **Use external command input box** and select **OK**.
7. The **Command** field appears below the usual input and display area of the **CLI Console**.
8. Type a command in this field and press **Enter**.

In the display area, the **CLI Console** widget displays your previous command interpreted into its character code equivalent, such as:

```
edit \743\601\613\743\601\652
```

and the command's output.

#### To enter non-ASCII characters in a Telnet/SSH client

1. On your management computer, start your Telnet or SSH client.
2. Configure your Telnet or SSH client to send and receive characters using UTF-8 encoding.  
Support for sending and receiving international characters varies by each Telnet/SSH client. Consult the documentation for your Telnet/SSH client.

3. Log in to the FortiGate unit.
4. At the command prompt, type your command and press **Enter**.

You may need to surround words that use encoded characters with single quotes ( ' ).

Depending on your Telnet/SSH client's support for your language's input methods and for sending international characters, you may need to interpret them into character codes before pressing Enter.

For example, you might need to enter:

```
edit '\743\601\613\743\601\652'
```

5. The CLI displays your previous command and its output.

## Screen paging

You can configure the CLI to pause after displaying each page's worth of text when displaying multiple pages of output. When the display pauses, the last line displays `--More--`. You can then either:

- press the **spacebar** to display the next page.
- type **q** to truncate the output and return to the command prompt.

This may be useful when displaying lengthy output, such as the list of possible matching commands for command completion, or a long list of settings. Rather than scrolling through or possibly exceeding the buffer of your terminal emulator, you can simply display one page at a time.

To configure the CLI Console to pause display when the screen is full:

```
config system console
  set output more
end
```

## Baud rate

You can change the default baud rate of the local console connection.

To change the baud rate enter the following commands:

```
config system console
  set baudrate {9600 | 19200 | 38400 | 57600 | 115200}
end
```

## Editing the configuration file on an external host

You can edit the FortiGate configuration on an external host by first backing up the configuration file to a TFTP server. Then edit the configuration file and restore it to the FortiGate unit.

Editing the configuration on an external host can be timesaving if you have many changes to make, especially if your plain text editor provides advanced features such as batch changes.

### To edit the configuration on your computer:

1. Use `execute backup` to download the configuration file to a TFTP server, such as your management computer.
2. Edit the configuration file using a plain text editor that supports Unix-style line endings.

Do not edit the first line. The first line(s) of the configuration file (preceded by a # character) contains information about the firmware version and FortiGate model. If you change the model number, the FortiGate unit will reject the configuration file when you attempt to restore it.

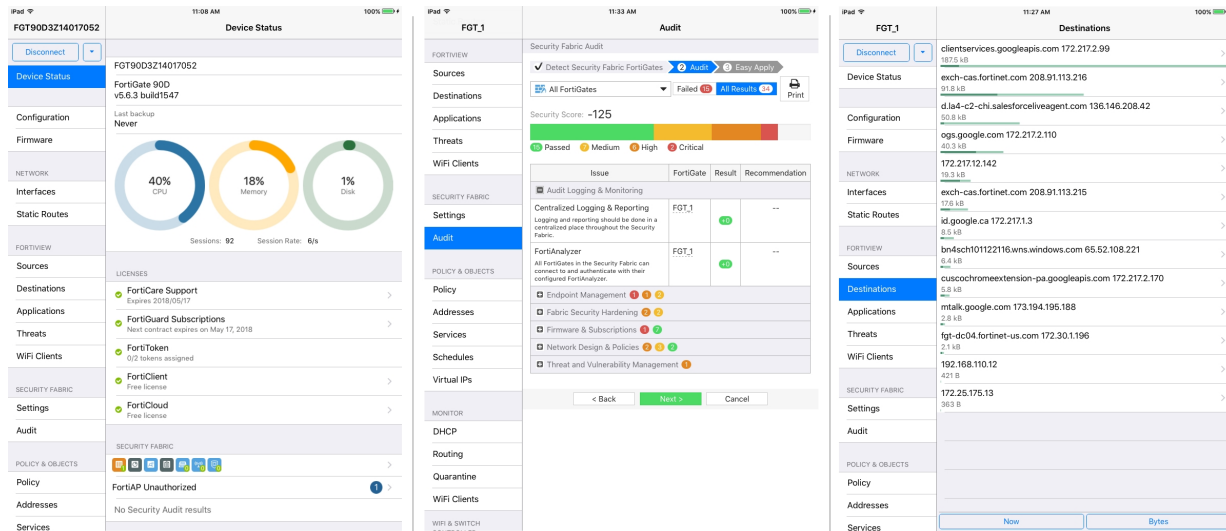

---

3. Use `execute restore` to upload the modified configuration file back to the FortiGate unit.

The FortiGate unit downloads the configuration file and checks that the model information is correct. If it is correct, the FortiGate unit loads the configuration file and checks each command for errors. If a command is invalid, the FortiGate unit ignores the command. If the configuration file is valid, the FortiGate unit restarts and loads the new configuration.

## FortiExplorer for iOS

FortiExplorer for iOS is a user-friendly application that helps you to quickly and easily configure, manage, and monitor FortiGate appliances using an iOS device. FortiExplorer lets you rapidly provision, deploy, and monitor Security Fabric components including FortiGate, FortiWiFi, and FortiAP devices.

FortiExplorer for iOS requires iOS 9.3 or later and is compatible with iPhone, iPad, and iPod Touch. It is supported by FortiOS 5.6+ and is [only available on the App Store](#) for iOS devices.

Advanced features are available with the purchase of FortiExplorer Pro. Paid features include the ability to add more than two devices and the ability to download firmware images from FortiCare.

Up to six members can use this app with 'Family Sharing' enabled in the App Store.

## Getting started with FortiExplorer

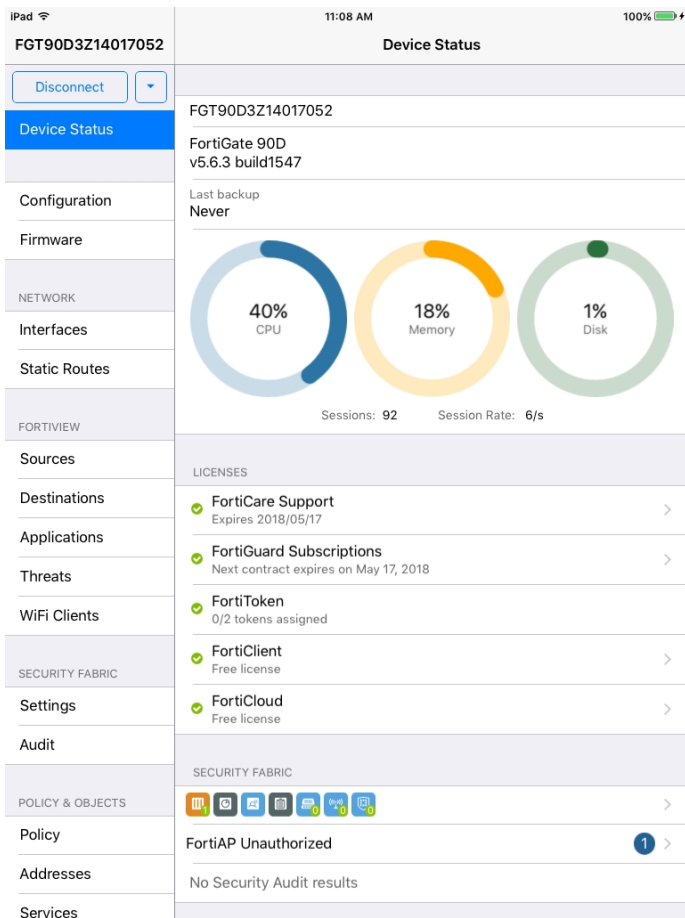

If your FortiGate is accessible on the wireless network, you can connect to it using FortiExplorer provided that your iOS device is on the same network (see [Connecting FortiExplorer to a FortiGate via WiFi](#)). Otherwise, you will need to physically connect your iOS device to the FortiGate using a USB cable (see below).

### Connecting FortiExplorer to a FortiGate via USB

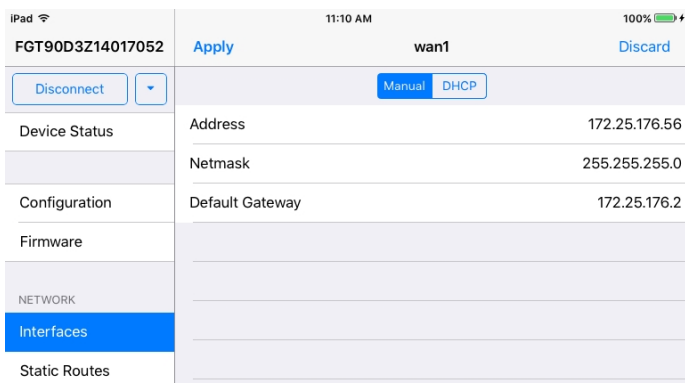

For the purpose of this document, we assume that you are just getting started; you do not have access to the FortiGate over the wireless network, and the FortiGate is in its factory configuration.

1. Connect your iOS device to your FortiGate's USB management port.  
If prompted on your iOS device, **Trust** this 'computer'.
2. Open the FortiExplorer app and select your FortiGate from the list under **USB Attached Device**.
3. On the **Login** screen, select **USB**.
4. Enter the default **Username** (**admin**) and leave the **Password** field blank.
5. You can opt to **Remember Password**. Tap **Done** when you are ready.

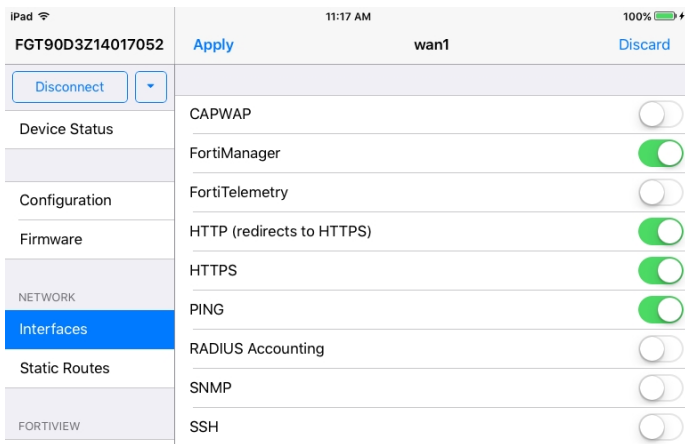

FortiExplorer opens the FortiGate management interface to the **Device Status** page:

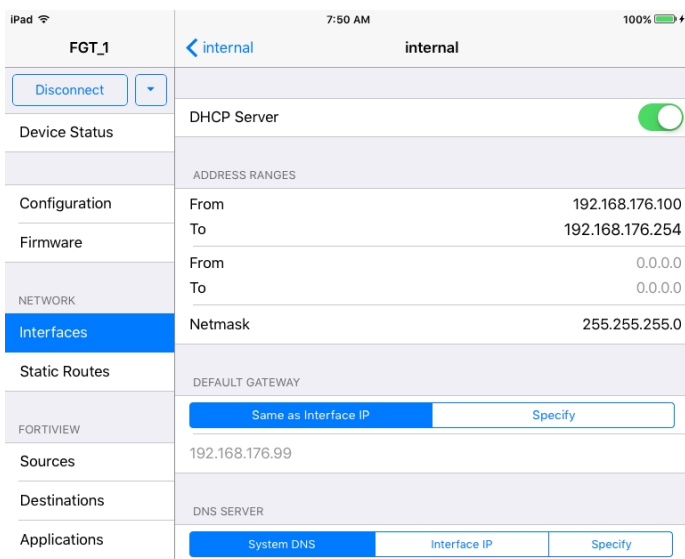

6. Go to **Network > Interfaces** and configure the WAN interface(s).  
 In the example, the **wan1** interface **Address** mode is set to **DHCP** by default. Set it to **Manual** and enter its **Address**, **Netmask**, and **Default Gateway**, and then **Apply** your changes.

7. (Optional) Configure **Administrative Access** to allow **HTTP** and **HTTPS** access.  
 This will allow administrators to access the FortiGate web-based manager using a web browser.

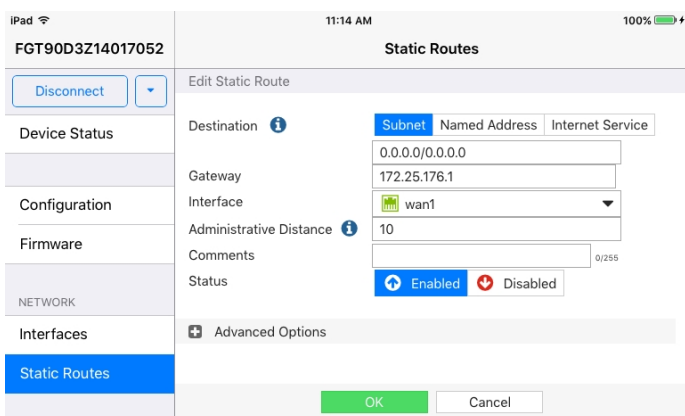

8. Go to **Network > Interfaces** and configure the local network (internal) interface. Set the **Address** mode as before and configure **Administrative Access** if desired.
9. Configure a **DHCP Server** for the internal network subnet.

Return to the internal interface using the  button at the top of the screen.

10. Go to **Network > Static Routes** and configure the static route to the gateway.

11. Go to **Policy & Objects > Policy** and edit the Internet access policy. As a best practice, provide a **Name** for the policy, enable the desired **Security Profiles**, and configure **Logging Options**. Select **OK** to finalize.

## Running a Security Fabric Audit

The FortiGate is now configured in a very basic state. Once you've configured the other potential elements of your network, such as other **Interfaces**, **Schedules**, or **Managed FortiAPs**, it is recommended that you run a **Security Fabric Audit** to identify potential vulnerabilities and highlight best practices that could be used to improve your network's overall security and performance.

Follow the steps of the Security Fabric Audit (under **Security Fabric > Audit**) to determine a **Security Score** for the selected device(s). The results should identify issues ranging from Medium to Critical importance, and may provide recommended actions where possible.

## Connecting FortiExplorer to a FortiGate via WiFi

If your FortiGate is accessible on the wireless network, you can connect to it using FortiExplorer provided that your iOS device is on the same network. Assuming this is the case:

1. Open the FortiExplorer app and select **Add** from the **Devices** page.
2. Enter the **Host** information and appropriate **Username** and **Password** credentials. If necessary, change the default **Port** number, and opt to **Remember Password**.

3. If the FortiGate device identity cannot be verified, click **Connect** at the prompt. FortiExplorer opens the FortiGate management interface to the **Device Status** page.

## Upgrading to FortiExplorer Pro

Paid features provided with the purchase of FortiExplorer Pro include the ability to add more than two devices and the ability to download firmware images from FortiCare.

- To upgrade to FortiExplorer Pro, open the FortiExplorer app, go to **Settings** and select **Upgrade to FortiExplorer Pro**. Follow the on-screen prompts.

## LED Specifications

The following section includes information regarding FortiGate LED status indicators.

- [Sample FortiGate faceplates](#)
- [LED status codes](#)
- [About alarm levels](#)
- [LED status codes for ports](#)

### Sample FortiGate faceplates

The faceplates indicate where the LEDs are typically found on desktop and mid-range FortiGate models.

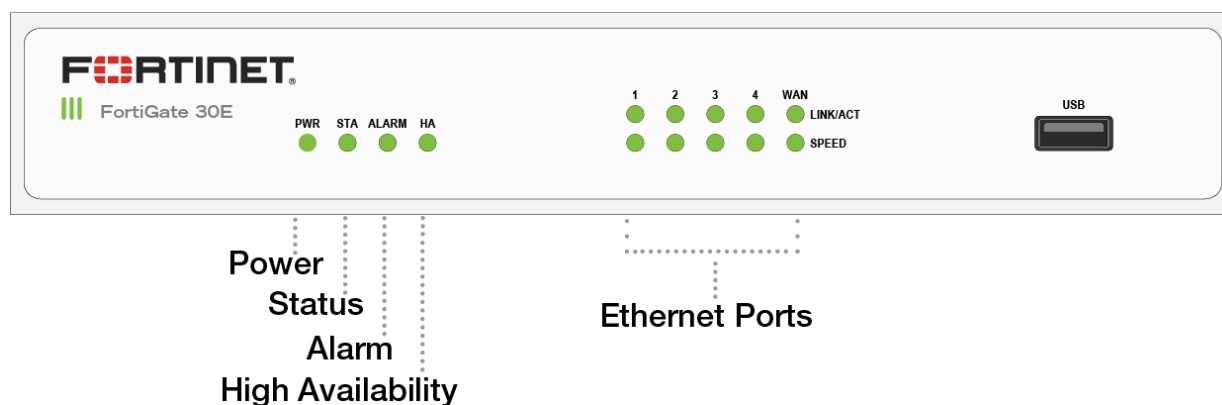

#### FortiGate 60C

#### FortiGate 100D

## FortiGate 30E

## LED status codes

LABEL	STATE	MEANING
PWR	Green	Power is On.
	Off	Power is Off.
STA	Green	Normal status.
	Flashing Green	Booting Up. If the FortiGate has a reset button, Flashing Green also means that the reset button was used.
	Red	The FortiGate has a critical alarm (see <a href="#">About Alarm Levels</a> ).
ALARM	Off	No alarms or the FortiGate has a minor alarm.
	Amber	The FortiGate has a major alarm.
	Red	The FortiGate has a critical alarm. The status LED will also be red.
		More information at <a href="#">About Alarm Levels</a> .
HA	Green	FortiGate is operating in an FGCP HA cluster.
	Red	A failover has occurred.
	Off	HA not configured.
		Failover operation feature not available in all units.

LABEL	STATE	MEANING
<b>WIFI</b>	Green	Wireless port is active.
	Flashing Green	Wireless interface is transmitting and receiving data.
	Off	Wireless interface is down.

## About alarm levels

Minor, major, and critical alarms are defined based on IPMI, ATCA, and Telco standards for naming alarms.

- A minor alarm (also called an IPMI non-critical (NC) alarm) indicates a temperature or a power level outside of the normal operating range that is not considered a problem. In the case of a minor temperature alarm, the system could respond by increasing fan speed. A non-critical threshold can be an upper non-critical (UNC) threshold (for example, a high temperature or a high power level) or a lower non-critical (LNC) threshold (for example, a low power level). The LEDs do not indicate minor alarms since user intervention is not required.
- A major alarm (also called an IPMI critical or critical recoverable (CR) alarm) indicates that the system itself cannot correct the cause for the alarm and that intervention is required. For example, the cooling system cannot provide enough cooling to reduce the temperature. It could also mean that conditions (e.g. temperature) are approaching the outside limit of the allowed operating range. A critical threshold can also be an upper critical (UC) threshold (e.g. a high temperature or a high power level) or a lower critical (LC) threshold (e.g. a low power level).
- A critical alarm (also called an IPMI non-recoverable (NR) alarm) indicates detection of a temperature or power level that is outside of the allowed operating range and could potentially cause physical damage.

## LED status codes for ports

TYPE OF PORT	STATE	MEANING
<b>Ethernet Ports Link / Activity</b>	Green	Connected.
	Flashing Green	Transmitting and receiving data.
	Off	No link established.
		On FortiGate models with front-facing ports, this LED is to the left of the port. On FortiGate models with ports at the back of the device, this LED is in the upper row.
<b>SFP Ports</b>	Green	Connected.
	Flashing Green	Transmitting and receiving data.
	Off	No link established.

TYPE OF PORT	STATE	MEANING
<b>Ethernet Ports Speed</b>	Green	Connected at 1Gbps.
	Amber	Connected at 100Mbps.
	Off	Not connected or connected at 10Mbps.
		On FortiGate models with front-facing ports, this LED is to the right of the port. On FortiGate models with ports at the back of the device, this LED is in the lower row.

## Inspection Mode

To control your FortiGate's security profile inspection mode in FortiOS 5.6, you can select **Flow-based** or **Proxy** inspection modes from **System > Settings**. Having control over flow and proxy mode is helpful if you want to ensure that only flow inspection mode is used.

In most cases proxy mode is preferred because more security profile features are available along with more configuration options for these individual features. Some implementations, however, may require all security profile scanning to only use flow mode. In this case, you can set your FortiGate to flow mode knowing that proxy mode inspection will not be used.

Setting up the FortiGate to operate in these new modes (or to operate in the other available operating modes) involves going to **System > Settings** and changing the **Inspection Mode** and **NGFW Mode**.

NGFW mode simplifies applying application control and web filtering to traffic by allowing you to add applications and web filtering profiles directly to policies.

Transparent proxy allows you to apply web authentication to HTTP traffic without using the explicit proxy.

### Changing inspection and policy modes

To change inspection modes, go to **System > Settings**. You can select **Flow-based** to operate in flow mode or **Proxy** to operate in proxy mode.

### NGFW policy mode

When you select **Flow-based** as the **Inspection Mode**, you have the option to select an **NGFW Mode**. **Profile-based** mode works the same as flow-based mode did in FortiOS 5.4.

In **Policy-based** mode, you add applications and web filtering profiles directly to a policy without having to first create and configure Application Control or Web Filtering profiles.

When you change to **Flow-based** inspection, all proxy mode profiles are converted to flow mode, removing any proxy settings. In addition, proxy-mode only features (for example, Web Application Profile) are removed from the GUI.

If your FortiGate has multiple VDOMs, you can set the inspection mode independently for each VDOM. Go to **System > VDOM**. Click **Edit** for the VDOM you wish to change and select the **Inspection Mode**.

### CLI syntax

The following CLI command can be used to configure inspection and policy modes:

```
config system settings
    set inspection-mode {proxy | flow}
    set policy-mode {standard | ngfw}
end
```

### Security profile features mapped to inspection mode

The table below lists FortiOS security profile features and shows whether they are available in flow-based or proxy-based inspection modes.

Security Profile Feature	Flow-based inspection	Proxy-based inspection
AntiVirus	x	x
Web Filter	x	x
DNS Filter	x	x
Application Control	x	x
Intrusion Protection	x	x
Anti-Spam		x
Data Leak Protection		x
VoIP		x
ICAP		x
Web Application Firewall		x
FortiClient Profiles	x	x
Proxy Options	x	x
SSL Inspection	x	x
SSH Inspection		x
Web Rating Overrides	x	x
Web Profile Overrides		x

From the GUI, you can only configure antivirus and web filter security profiles in proxy mode. From the CLI, you can configure flow-based antivirus profiles, web filter profiles, and DLP profiles and they will appear on the GUI and include their inspection mode setting. Flow-based profiles created when in flow mode are still available when you switch to proxy mode.

In flow mode, antivirus and web filter profiles only include flow-mode features. Web filtering and virus scanning is still done with the same engines and to the same accuracy, but some inspection options are limited or not available in flow mode. Application control, intrusion protection, and FortiClient profiles are not affected when switching between flow and proxy mode.

Even though VoIP profiles are not available from the GUI in flow mode, the FortiGate can process VoIP traffic. In this case the appropriate session helper is used (for example, the SIP session helper).

Setting flow or proxy mode doesn't change the settings available from the CLI. However, when in flow mode you can't save security profiles that are set to proxy mode.

You can also add proxy-only security profiles to firewall policies from the CLI. So, for example, you can add a VoIP profile to a security policy that accepts VoIP traffic. This practice isn't recommended because the setting will not be visible from the GUI.

### Proxy mode and flow mode antivirus and web filter profile options

The following tables list the antivirus and web filter profile options available in proxy and flow modes.

#### Antivirus features in proxy and flow mode

Feature	Proxy	Flow
Scan Mode (Quick or Full)		<b>x</b>
Detect viruses (Block or Monitor)	<b>x</b>	<b>x</b>
Inspected protocols	<b>x</b>	(all relevant protocols are inspected)
Inspection Options	<b>x</b>	<b>x</b> (not available for quick scan mode)
Treat Windows Executables in Email Attachments as Viruses	<b>x</b>	<b>x</b>
Send Files to FortiSandbox Appliance for Inspection	<b>x</b>	<b>x</b>
Use FortiSandbox Database	<b>x</b>	<b>x</b>
Include Mobile Malware Protection	<b>x</b>	<b>x</b>

#### Web Filter features in proxy and flow mode

Feature	Proxy	Flow
FortiGuard category based filter	<b>x</b>	<b>x</b> (show, allow, monitor, block)
Category Usage Quota	<b>x</b>	
Allow users to override blocked categories (on some models)	<b>x</b>	
Search Engines	<b>x</b>	

Feature		Proxy Flow	
	Enforce 'Safe Search' on Google, Yahoo!, Bing, Yandex	x	
	Restrict YouTube Access	x	
	Log all search keywords	x	
Static URL Filter		x	x
	Block invalid URLs	x	
	URL Filter	x	x
	Block malicious URLs discovered by FortiSandbox	x	x
	Web Content Filter	x	x
Rating Options		x	x
	Allow websites when a rating error occurs	x	x
	Rate URLs by domain and IP Address	x	x
	Block HTTP redirects by rating	x	
	Rate images by URL	x	
Proxy Options		x	
	Restrict Google account usage to specific domains	x	
	Provide details for blocked HTTP 4xx and 5xx errors	x	
	HTTP POST Action	x	
	Remove Java Applets	x	
	Remove ActiveX	x	
	Remove Cookies	x	
	Filter Per-User Black/White List	x	

## Basic Administration

This section contains information about basic FortiGate administration that can be done after you have installed the unit in your network.

While this section mainly focuses on accomplishing tasks with the GUI, some tasks include instructions to use the CLI. You can access the CLI using the GUI or FortiExplorer, or via SSH or Telnet connection. For more information about the CLI, see [Using the CLI](#).

## Registration

In order to have full access to Fortinet Support and FortiGuard Services, you must register your FortiGate.

### Registering your FortiGate:

1. Go to the **Dashboard** and locate the **Licenses** widget.
2. Click on **FortiCare Support** to display a pop-up window and **Register**.
3. In the pop-up window, either use an existing Fortinet Support account or create a new one. Select your **Country** and **Reseller**.
4. Select **OK**.

FortiGate platforms do not impose any limitations on the number or type of customers, users, devices, IP addresses, or number of VPN clients being served by the platform. Such factors are limited solely by the hardware capacity of each given model.

## System Settings

There are several system settings that should be configured once your FortiGate is installed:

- [Default administrator password](#)
- [Settings](#)
  - [Changing the host name](#)
  - [Central Management](#)
  - [System Time](#)
  - [Administration Settings](#)
  - [Password Policy](#)
  - [View Settings](#)
- [Administrator password retries and lockout time](#)

### Default administrator password

By default, your FortiGate has an administrator account set up with the username `admin` and no password. In order to prevent unauthorized access to the FortiGate, it is highly recommended that you add a password to this account.

**To change the default password:**

1. Go to **System > Administrators**.
2. Edit the **admin** account.
3. Select **Change Password**.
4. Enter the **New Password** and re-enter the password for confirmation.
5. Select **OK**.

For details on selecting a password and password best practices, see the section on [Passwords](#).

It is also recommended to change the user name of this account; however, since you cannot change the user name of an account that is currently in use, a second administrator account will need to be created in order to do this. For more information about creating and using administrator accounts, see the Administrators section of the [System Administration](#) chapter.

## Settings

Settings can be accessed by going to **System > Settings**. On this page, you can change the **Host name**, designate the centralized security management for your FortiGate in **Central Management**, set the system time and identify time zone in **System Time**, configure HTTP, HTTPS, SSH, and Telnet ports as well as idle timeout in **Administration Settings**, designate the **Password Policy**, and manage display options and designate inspection mode in **View Settings**.

### Changing the host name

The host name of your FortiGate appears in the **Hostname** row in the **System Information** widget on the Dashboard. The host name also appears at the CLI prompt when you are logged in to the CLI, and as the SNMP system name.

**To change the host name on the FortiGate**

Go to **System > Settings** and type in the new name in the **Host name** row. The only administrators that can change a FortiGate's host name are administrators whose admin profiles permit system configuration write access. If the FortiGate is part of an HA cluster, you should use a unique host name to distinguish the FortiGate from others in the cluster.

### Central Management

You can manage any size Fortinet security infrastructure, from a few devices to thousands of appliances, by using FortiManager or FortiCloud. You can configure your FortiGate for either of these centralized security management services through Central Management. Be sure that you have registered your device with the FortiManager appliance or FortiCloud host. For more information on configuring your FortiGate for Central Management, see [Adding a FortiGate to FortiManager](#) or [FortiCloud](#).

### System Time

For effective scheduling and logging, the FortiGate system time and date should be accurate. You can either manually set the system time and date or configure the FortiGate to automatically synchronize with a Network Time Protocol (NTP) server.

NTP enables you to keep the FortiGate time synchronized with other network systems. By enabling NTP on the FortiGate, FortiOS will check with the NTP server you select at the configured intervals. This will also ensure that logs and other time-sensitive settings on the FortiGate are correct.

The FortiGate maintains its internal clock using a built-in battery. At start up, the time reported by the FortiGate will indicate the hardware clock time, which may not be accurate. When using NTP, the system time might change after the FortiGate has successfully obtained the time from a configured NTP server.

By default, FortiOS has the daylight savings time configuration enabled. The system time must be manually adjusted after daylight saving time ends. To disable DST, enter the following commands in the CLI:

```
config system global
  set dst disable
end
```

### To set the date and time

1. Go to the **System > Settings**.
2. Under **System Time**, select your **Time Zone** by using the drop-down menu.
3. **Set Time** by either selecting **Synchronize with NTP Server** or **Manual settings**. If you select synchronization, you can either use the default FortiGuard servers or specify a custom server. You can also set the **Sync interval**.
4. If you use an NTP server, you can identify a specific interface for this self-originating traffic by enabling **Setup device as local NTP server**.
5. Select **Apply**.

### Administration Settings

In order to improve security, you can change the default port configurations for administrative connections to the FortiGate. When connecting to the FortiGate when the port has changed, the port must be included, such as `https://<ip_address>:<port>`. For example, if you are connecting to the FortiGate using port 99, the URL would be `https://192.168.1.99:99`.

### To configure the port settings:

1. Go to **System > Settings**.
2. Under **Administration Settings**, change the port numbers for HTTP, HTTPS, SSH, and/or Telnet as needed. You can also select **Redirect to HTTPS** in order to avoid HTTP being used for the administrators.
3. Select **Apply**.

When you change the default port number for HTTP, HTTPS, SSH, or Telnet, ensure that the port number is unique. If a conflict exists with a particular port, a warning message will appear.

By default, the GUI disconnects administrative sessions if no activity occurs for five minutes. This prevents someone from using the GUI if the management PC is left unattended.

### To change the idle timeout

1. Go to **System > Settings**.
2. In the **Administration Settings** section, enter the time in minutes in the **Idle timeout** field.
3. Select **Apply**.

## Password Policy

The FortiGate includes the ability to create a password policy for administrators and IPsec pre-shared keys. With this policy, you can enforce regular changes and specific criteria for a password including:

- minimum length between 8 and 64 characters.
- if the password must contain uppercase (A, B, C) and/or lowercase (a, b, c) characters.
- if the password must contain numbers (1, 2, 3).
- if the password must contain special or non-alphanumeric characters (!, @, #, \$, %, ^, &, \*, (, and )).
- where the password applies (admin or IPsec or both).
- the duration of the password before a new one must be specified.

### To create a password policy - GUI

1. Go to **System > Settings**.
2. Configure **Password Policy** settings as required.
3. Click **Apply**.

If you add a password policy or change the requirements on an existing policy, the next time that administrator logs into the FortiGate, they are prompted to update their password to meet the new requirements before proceeding to log in.

For information about recovering a lost password and enhancements to the process, see: [Resetting a lost Admin password](#) on the Fortinet Cookbook site.

## View Settings

Three settings can change the presentation of information in the GUI: **Language**, **Lines per page**, and **Theme**.

To change the language, go to **System > Settings**. Select the language you want from the **Language** drop-down list: English (the default), French, Spanish, Portuguese, Japanese, Traditional Chinese, Simplified Chinese, or Korean. For best results, you should select the language that is used by the management computer.

To change the number of lines per page displayed in the GUI tables, set **Lines per page** to a value between 20 and 1,000. The default is 50 lines per page.

Five color themes are currently available: Green (the default), Red, Blue, Melongene, and Mariner. To change your theme, select the color from the **Theme** drop-down list.

This is also where you select either **Flow-based** or **Proxy Inspection Mode**. If you select Flow-based mode, then you need to specify if it is **NGFW Profile-based** or **NGFW Policy-based** inspection.

## Administrator password retries and lockout time

By default, the FortiGate sets the number of password retries at three, allowing the administrator a maximum of three attempts to log into their account before locking the account for a set amount of time.

Both the number of attempts (`admin-lockout-threshold`) and the wait time before the administrator can try to enter a password again (`admin-lockout-duration`) can be configured within the CLI.

### To configure the lockout options:

```
config system global
    set admin-lockout-threshold <failed_attempts>
```

```
set admin-lockout-duration <seconds>
end
```

The default value of `admin-lockout-threshold` is 3 and the range of values is between 1 and 10. The `admin-lockout-duration` is set to 60 seconds by default and the range of values is between 1 and 4294967295 seconds.

Keep in mind that the higher the lockout threshold, the higher the risk that someone may be able to break into the FortiGate unit.

**Example:**

To set the `admin-lockout-threshold` to one attempt and the `admin-lockout-duration` to a five minute duration before the administrator can try to log in again, enter the commands:

```
config system global
set admin-lockout-threshold 1
set admin-lockout-duration 300
end
```

If the time span between the first failed login attempt and the `admin-lockout-threshold` failed login attempt is less than `admin-lockout-duration`, the lockout will be triggered.

---

## Passwords

Using secure passwords are vital for preventing unauthorized access to your FortiGate. When changing the password, consider the following to ensure better security:

- Do not make passwords that are obvious, such as the company name, administrator names, or other obvious words or phrases.
- Use numbers in place of letters, for example, `passw0rd`.
- Administrator passwords can be up to 64 characters.
- Include a mixture of letters, numbers, and upper and lower case.
- Use multiple words together, or possibly even a sentence, for example `keytothehighway`.
- Use a password generator.
- Change the password regularly and always make the new password unique and not a variation of the existing password, such as changing from `password` to `password1`.
- Make note of the password and store it in a safe place away from the management computer, in case you forget it or ensure that at least two people know the password in the event that one person becomes ill, is away on vacation, or leaves the company. Alternatively, have two different admin logins.

Downgrades will typically maintain the administrator password. If you need to downgrade to FortiOS 4.3, remove the password before the downgrade, then log in after the downgrade and re-configure the password.

## Password policy

The FortiGate includes the ability to create a password policy for administrators and IPsec pre-shared keys. With this policy, you can enforce regular changes and specific criteria for a password including:

- minimum length between 8 and 64 characters.
- if the password must contain uppercase (A, B, C) and/or lowercase (a, b, c) characters.
- if the password must contain numbers (1, 2, 3).
- if the password must contain special or non-alphanumeric characters (!, @, #, \$, %, ^, &, \*, (, and )).
- where the password applies (admin or IPsec or both).
- the duration of the password before a new one must be specified.

#### **To create a password policy - GUI**

1. Go to **System > Settings**.
2. Configure **Password Policy** settings as required.
3. Click **Apply**.

If you add a password policy or change the requirements on an existing policy, the next time that administrator logs into the FortiGate, they are prompted to update their password to meet the new requirements before proceeding to log in.

For information about recovering a lost password and enhancements to the process, see: [Resetting a lost Admin password](#) on the Fortinet Cookbook site.

## Firmware

Fortinet periodically updates the FortiGate firmware to include new features and resolve important issues. After you have registered your FortiGate unit, you can download firmware updates from the support web site, <https://support.fortinet.com>.

Before you install any new firmware, be sure to follow the steps below:

- Review the [Release Notes](#) for a new firmware release.
- Review the [Supported Upgrade Paths](#) Sys Admin note on the Fortinet Cookbook site to make sure the upgrade from your current image to the desired new image is supported.
- Backup the current configuration, including local certificates.
- Test the new firmware until you are satisfied that it applies to your configuration.

Installing new firmware without reviewing release notes or testing the firmware may result in changes to settings or unexpected issues.

Only FortiGate admin users and administrators whose access profiles contain system read and write privileges can change the FortiGate firmware.

---

### Backing up the current configuration

You should always back up the configuration before installing new firmware, in case you need to restore your FortiGate configuration.

#### To create a local backup:

1. Open to the administrator's dropdown menu in the top-right corner of the GUI and select **Configuration > Backup**.
2. Choose either **Local PC** or **USB Disk** to save the configuration file. The USB option will not be available if there is no USB drive in the USB port.
3. If desired, select **Encryption**.
4. Select **OK**.

For more information, see [Configuration Backups](#).

### Downloading firmware

Firmware images for all FortiGate units are available on the Fortinet Customer Support website, <https://support.fortinet.com>.

#### To download firmware:

1. Log into the site using your user name and password.
2. Go to **Download > Firmware Images**.
3. A list of Release Notes is shown. If you have not already done so, download and review the Release Notes for the firmware you wish to upgrade your FortiGate unit to.
4. Select **Download**.

Firmware can also be downloaded using FTP; however, as FTP is not an encrypted file transferring protocol, HTTPS downloading is recommended.

5. Navigate to the folder for the firmware version you wish to use.
6. Select your FortiGate model from the list. If your unit is a FortiWiFi, the firmware will have a filename starting with 'FWF'.
7. Save the firmware image to your computer.

## Testing new firmware

The integrity of firmware images downloaded from Fortinet's support portal can be verified using a file checksum. A file checksum that does not match the expected value indicates a corrupt file. The corruption could be caused by errors in transfer or by file modification. A list of expected checksum values for each build of released code is available on Fortinet's support portal.

Image integrity is also verified when the FortiGate is booting up. This integrity check is done through a cyclic redundancy check (CRC). If the CRC fails, the FortiGate unit will encounter an error during the boot process.

Lastly, firmware images are signed and the signature is attached to the code as it is built. When upgrading an image, the running OS will generate a signature and compare it with the signature attached to the image. If the signatures do not match, the new OS will not load.

## Testing before installation

FortiOS lets you test a new firmware image by installing the firmware image from a system reboot and saving it to system memory. After completing this procedure, the FortiGate unit operates using the new firmware image with the current configuration. This new firmware image is not permanently installed. The next time the FortiGate unit restarts, it operates with the originally installed firmware image using the current configuration. If the new firmware image operates successfully, you can install it permanently using the procedure explained in [Testing new firmware on page 341](#).

To use this procedure, you must connect to the CLI using the FortiGate console port and an RJ-45 to DB-9 or null modem cable. This procedure temporarily installs a new firmware image using your current configuration.

For this procedure, you must install a TFTP server that you can connect to from the FortiGate internal interface. The TFTP server should be on the same subnet as the internal interface.

### To test the new firmware image:

1. Connect to the CLI using an RJ-45 to DB-9 or null modem cable.
2. Make sure the TFTP server is running.
3. Copy the new firmware image file to the root directory of the TFTP server.
4. Make sure the FortiGate unit can connect to the TFTP server using the `execute ping` command.
5. Enter the following command to restart the FortiGate unit:  

```
execute reboot
```
6. As the FortiGate unit reboots, press any key to interrupt the system startup. As the FortiGate unit starts, a series of system startup messages appears:  

```
Press any key to display configuration menu....
```

7. Immediately press any key to interrupt the system startup.

You have only three (3) seconds to press any key. If you do not press a key quickly enough, the FortiGate unit reboots and you must log in and repeat the `execute reboot` command.

If you successfully interrupt the startup process, the following messages appears:

```
[G]: Get firmware image from TFTP server.
[F]: Format boot device.
[B]: Boot with backup firmware and set as default
[C]: Configuration and information
[Q]: Quit menu and continue to boot with default firmware.
[H]: Display this list of options.
Enter G, F, Q, or H:
```

8. Type **G** to get the new firmware image from the TFTP server. The following message appears:  
Enter TFTP server address [192.168.1.168]:
9. Type the address of the TFTP server and press **Enter**. The following message appears:  
Enter Local Address [192.168.1.188]:
10. Type an IP address of the FortiGate unit to connect to the TFTP server. The IP address must be on the same network as the TFTP server.

Make sure you do not enter the IP address of another device on this network.

The following message appears:

```
Enter File Name [image.out]:
```

11. Enter the firmware image file name and press **Enter**. The TFTP server uploads the firmware image file to the FortiGate unit and the following appears:  
Save as Default firmware/Backup firmware/Run image without saving: [D/B/R]
12. Type **R**. The FortiGate image is installed to system memory and the FortiGate unit starts running the new firmware image, but with its current configuration.

You can test the new firmware image as required. When done testing, you can reboot the FortiGate unit, and the FortiGate unit will resume using the firmware that was running before you installed the test firmware.

## Upgrading the firmware

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date. You can also use the CLI command `execute update-now` to update the antivirus and attack definitions. For more information, see the [System Administration](#) handbook.

Always remember to back up your configuration before making any changes to the firmware.

Be sure to read the topics on [downloading](#) and [testing](#) firmware before upgrading.

**To upgrade the firmware - GUI:**

1. Log into the GUI as the admin administrative user.
2. Go to **System > Firmware**.
3. Under **Upload Firmware**, select **Browse** and locate the firmware image file.
4. Select **OK**.

The FortiGate unit uploads the firmware image file, upgrades to the new firmware version, restarts, and displays the FortiGate login. This process takes a few minutes.

**To upgrade the firmware - CLI:**

Before you begin, ensure you have a TFTP server running and accessible to the FortiGate unit.

1. Make sure the TFTP server is running.
2. Copy the new firmware image file to the root directory of the TFTP server.
3. Log into the CLI.
4. Make sure the FortiGate unit can connect to the TFTP server. You can use the following command to ping the computer running the TFTP server. For example, if the IP address of the TFTP server is 192.168.1.168:

```
execute ping 192.168.1.168
```

5. Enter the following command to copy the firmware image from the TFTP server to the FortiGate unit:

```
execute restore image tftp <filename> <tftp_ipv4>
```

Where `<name_str>` is the name of the firmware image file and `<tftp_ipv4>` is the IP address of the TFTP server. For example, if the firmware image file name is `image.out` and the IP address of the TFTP server is 192.168.1.168, enter:

```
execute restore image tftp image.out 192.168.1.168
```

The FortiGate unit responds with the message:

```
This operation will replace the current firmware version!  
Do you want to continue? (y/n)
```

6. Type `y`. The FortiGate unit uploads the firmware image file, upgrades to the new firmware version, and restarts. This process takes a few minutes.
7. Reconnect to the CLI.
8. Update antivirus and attack definitions, by entering:

```
execute update-now
```

**Reverting to a previous firmware version**

The following procedure reverts the FortiGate unit to its factory default configuration and deletes any configuration settings. If you are reverting to a previous FortiOS version, you might not be able to restore the previous configuration from the backup configuration file.

Always remember to back up your configuration before making any changes to the firmware.

---

**To revert to a previous firmware version - GUI:**

1. Log into the GUI as the admin user.
2. Go to **System > Firmware**.
3. Under **Upload Firmware**, select **Browse** and locate the firmware image file.
4. Select **OK**.

The FortiGate unit uploads the firmware image file, reverts to the old firmware version, resets the configuration, restarts, and displays the FortiGate login. This process takes a few minutes.

**To revert to a previous firmware version - CLI:**

Before beginning this procedure, it is recommended that you:

- Backup the FortiGate unit system configuration using the command `execute backup config`.
- Backup the IPS custom signatures using the command `execute backup ipsuserdefsig`.
- Backup web content and email filtering lists.

To use the following procedure, you must have a TFTP server the FortiGate unit can connect to.

1. Make sure the TFTP server is running.
2. Copy the firmware image file to the root directory of the TFTP server.
3. Log into the FortiGate CLI.
4. Make sure the FortiGate unit can connect to the TFTP server by using the `execute ping` command.
5. Enter the following command to copy the firmware image from the TFTP server to the FortiGate unit:

```
execute restore image tftp <name_str> <tftp_ipv4>
```

Where `<name_str>` is the name of the firmware image file and `<tftp_ipv4>` is the IP address of the TFTP server. For example, if the firmware image file name is `imagev28.out` and the IP address of the TFTP server is `192.168.1.168`, enter:

```
execute restore image tftp image28.out 192.168.1.168
```

The FortiGate unit responds with this message:

```
This operation will replace the current firmware version!
Do you want to continue? (y/n)
```

6. Type `y`. The FortiGate unit uploads the firmware image file. After the file uploads, a message similar to the following appears:
 

```
Get image from tftp server OK.
Check image OK.
This operation will downgrade the current firmware version!
Do you want to continue? (y/n)
```

7. Type `y`. The FortiGate unit reverts to the old firmware version, resets the configuration to factory defaults, and restarts. This process takes a few minutes.
8. Reconnect to the CLI.
9. To restore your previous configuration, if needed, use the command:

```
execute restore config <name_str> <tftp_ipv4>
```

10. Update antivirus and attack definitions using the command:

```
execute update-now
```

## Installing firmware from a system reboot - CLI

In the event that the firmware upgrade does not load properly and the FortiGate unit will not boot, or continuously reboots, it is best to perform a fresh install of the firmware from a reboot using the CLI.

This procedure installs a firmware image and resets the FortiGate unit to default settings. You can use this procedure to upgrade to a new firmware version, revert to an older firmware version, or re-install the current firmware.

To use this procedure, you must connect to the CLI using the FortiGate console port and a RJ-45 to DB-9, or null modem cable. This procedure reverts the FortiGate unit to its factory default configuration.

For this procedure you install a TFTP server that you can connect to from the FortiGate internal interface. The TFTP server should be on the same subnet as the internal interface.

Before beginning this procedure, ensure you backup the FortiGate unit configuration.

If you are reverting to a previous FortiOS version, you might not be able to restore the previous configuration from the backup configuration file.

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date.

### To install firmware from a system reboot:

1. Connect to the CLI using the RJ-45 to DB-9 or null modem cable.
2. Make sure the TFTP server is running.
3. Copy the new firmware image file to the root directory of the TFTP server.
4. Make sure the internal interface is connected to the same network as the TFTP server.
5. To confirm the FortiGate unit can connect to the TFTP server, use the following command to ping the computer running the TFTP server. For example, if the IP address of the TFTP server is 192.168.1.168:

```
execute ping 192.168.1.168
```

6. Enter the following command to restart the FortiGate unit.

```
execute reboot
```

The FortiGate unit responds with the following message:

```
This operation will reboot the system!  
Do you want to continue? (y/n)
```

7. Type `y`. As the FortiGate unit starts, a series of system startup messages appears. When the following messages appears:

```
Press any key to display configuration menu.....
```

Immediately press any key to interrupt the system startup.

You have only three (3) seconds to press any key. If you do not press a key quickly enough, the FortiGate unit reboots and you must log in and repeat the `execute reboot` command.

---

If you successfully interrupt the startup process, the following messages appears:

```
[G]: Get firmware image from TFTP server.  
[F]: Format boot device.
```

[B]: Boot with backup firmware and set as default  
 [C]: Configuration and information  
 [Q]: Quit menu and continue to boot with default firmware.  
 [H]: Display this list of options.  
 Enter G, F, Q, or H:

8. Type **G** to get to the new firmware image form the TFTP server. The following message appears:

Enter TFTP server address [192.168.1.168]:

9. Type the address of the TFTP server and press **Enter**. The following message appears:

Enter Local Address [192.168.1.188]:

10. Type an IP address the FortiGate unit can use to connect to the TFTP server. The IP address can be any IP address that is valid for the network to which the interface is connected.

Make sure you do not enter the IP address of another device on this network.

The following message appears:

Enter File Name [image.out]:

11. Enter the firmware image filename and press **Enter**.  
 The TFTP server uploads the firmware image file to the FortiGate unit and a message similar to the following appears:

Save as Default firmware/Backup firmware/Run image without saving: [D/B/R]

12. Type **D**. The FortiGate unit installs the new firmware image and restarts. The installation might take a few minutes to complete.

## Restoring firmware from a USB key - CLI

1. Log into the CLI.
2. Enter the following command to restore an unencrypted configuration file:

```
execute restore image usb Restore image from USB disk.
{string} Image file name on the USB disk.
```

The FortiGate unit responds with the following message:

```
This operation will replace the current firmware version!
Do you want to continue? (y/n)
```

3. Type **y**.

## Configuration revision

You can manage multiple versions of configuration files on models that have a 512MB flash memory and higher. Revision control requires either a configured central management server or the local hard drive, if your FortiGate has this feature. Typically, configuration backup to local drive is not available on lower-end models.

The central management server can either be a FortiManager unit or FortiCloud.

If central management is not configured on your FortiGate unit, a message appears instructing you to either:

- Enable central management, **or**
- obtain a valid license.

When revision control is enabled on your FortiGate unit, and configuration backups have been made, a list of saved revisions of those backed-up configurations appears.

Configuration revisions are viewed by clicking on **admin** in the upper right-hand corner of the screen and selecting **Configuration > Revisions**.

## Controlled upgrade

Using a controlled upgrade, you can upload a new version of the FortiOS firmware to a separate partition in the FortiGate memory for later upgrade. The FortiGate unit can also be configured so that when it is rebooted, it will automatically load the new firmware (CLI only). Using this option, you can stage a number of FortiGate units to do an upgrade simultaneously to all devices using FortiManager or script.

### To load the firmware for later installation - CLI:

```
execute restore secondary-image {ftp | tftp | usb} <filename_str>
```

To set the FortiGate unit so that when it reboots, the new firmware is loaded, use the CLI command . . .

```
execute set-next-reboot {primary | secondary}
```

where {primary | secondary} is the partition with the preloaded firmware.

## Configuration Backups

Once you successfully configure the FortiGate, it is extremely important that you backup the configuration. In some cases, you may need to reset the FortiGate to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device will have to be recreated, unless a backup can be used to restore it. You should also backup the local certificates, as the unique SSL inspection CA and server certificates that are generated by your FortiGate by default are not saved in a system backup.

It is also recommended that you backup the configuration after *any* future changes are made, to ensure you have the most current configuration available. Also, backup the configuration before any upgrades of the FortiGate's firmware. Should anything happen to the configuration during the upgrade, you can easily restore the saved configuration.

Always backup the configuration and store it on the management computer or off-site. You have the option to save the configuration file to various locations including the local PC, USB key, FTP, and TFTP server. The last two are configurable through the CLI only.

If you have VDOMs, you can back up the configuration of the entire FortiGate or only a specific VDOM. Note that if you are using FortiManager or FortiCloud, full backups are performed and the option to backup individual VDOMs will not appear.

### Backing up the configuration using the GUI

1. Click on **admin** in the upper right-hand corner of the screen and select **Configuration > Backup**.
2. Direct the backup to your **Local PC** or to a **USB Disk**.

The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can also backup to the FortiManager using the CLI.

3. If VDOMs are enabled, indicate whether the scope of the backup is for the entire FortiGate configuration (**Global**) or only a specific VDOM configuration (**VDOM**).
4. If backing up a VDOM configuration, select the VDOM name from the list.
5. Select **Encryption**.  
Encryption must be enabled on the backup file to back up VPN certificates.
6. Enter a password and enter it again to confirm it. You will need this password to restore the file.
7. Select **OK**.
8. The web browser will prompt you for a location to save the configuration file. The configuration file will have a .conf extension.

## Backing up the configuration using the CLI

Use one of the following commands:

```
execute backup config management-station <comment>
```

or:

```
execute backup config usb <backup_filename> [<backup_password>]
```

or for FTP, note that port number, username are optional depending on the FTP site:

```
execute backup config ftp <backup_filename> <ftp_server> [<port>] [<user_name>]  
[<password>]
```

or for TFTP:

```
execute backup config tftp <backup_filename> <tftp_servers> <password>
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config vdom  
edit <vdom_name>
```

## Backup and restore the local certificates

This procedure exports a server (local) certificate and private key together as a password protected PKCS12 file. The export file is created through a customer-supplied TFTP server. Ensure that your TFTP server is running and accessible to the FortiGate before you enter the command.

### To back up the local certificates:

Connect to the CLI and use the following command:

```
execute vpn certificate local export tftp <cert_name> <filename> <tftp_ip>
```

where:

- <cert\_name> is the name of the server certificate.
- <filename> is a name for the output file.
- <tftp\_ip> is the IP address assigned to the TFTP server host interface.

### To restore the local certificates - GUI:

1. Move the output file from the TFTP server location to the management computer.
2. Go to **System > Certificates** and select **Import**.
3. Select the appropriate type of certificate from the dropdown menu and fill in any required fields.

4. Select **Upload**. Browse to the location on the management computer where the exported file has been saved, select the file and select **Open**.
5. If required, enter the **Password** needed to upload the exported file.
6. Select **OK**.

#### To restore the local certificates - CLI:

Connect to the CLI and use the following command:

```
execute vpn certificate local import tftp <filename> <tftp_ip>
```

### Backup and restore a configuration file using SCP

You can use secure copy protocol (SCP) to download the configuration file from the FortiGate as an alternative method of backing up the configuration file or an individual VDOM configuration file. This is done by enabling SCP for an administrator account and enabling SSH on a port used by the SCP client application to connect to the FortiGate. SCP is enabled using the CLI commands:

```
config system global
    set admin-scp enable
end
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config global
    set admin-scp enable
end
config vdom
    edit <vdom_name>
```

### Enable SSH access on the interface

SCP uses the SSH protocol to provide secure file transfer. The interface you use for administration must allow SSH access.

#### To enable SSH - GUI:

1. Go to **Network > Interfaces**.
2. Select the interface you use for administrative access and select **Edit**.
3. In the **Administrative Access** section, select **SSH**.
4. Select **OK**.

#### To enable SSH - CLI:

```
config system interface
    edit <interface_name>
        set allowaccess ping https ssh
    end
```

When adding to, or removing a protocol, you must type the entire list again. For example, if you have an access list of HTTPS and SSH, and you want to add PING, you must type:

```
set allowaccess https ssh ping
```

---

## Using the SCP client

The FortiGate downloads the configuration file as `sys_conf`. Use the following syntax to download the file:

### Linux

```
scp admin@<FortiGate_IP>:fgt-config <location>
```

### Windows

```
pscp admin@<FortiGate_IP>:fgt-config <location>
```

The following examples show how to download the configuration file from a FortiGate-100D, at IP address 172.20.120.171, using Linux and Windows SCP clients.

### Linux client example

To download the configuration file to a local directory called `~/config`, enter the following command:

```
scp admin@172.20.120.171:fgt-config ~/config
```

Enter the admin password when prompted.

### Windows client example

To download the configuration file to a local directory called `c:\config`, enter the following command in a Command Prompt window:

```
pscp admin@172.20.120.171:fgt-config c:\config
```

Enter the admin password when prompted.

## SCP public-private key authentication

SCP authenticates itself to the FortiGate in the same way as an administrator using SSH accesses the CLI. Instead of using a password, you can configure the SCP client and the FortiGate with a public-private key pair.

### To configure public-private key authentication:

1. Create a public-private key pair using a key generator compatible with your SCP client.
2. Save the private key to the location on your computer where your SSH keys are stored.  
This step depends on your SCP client. The Secure Shell key generator automatically stores the private key.

3. Copy the public key to the FortiGate using the CLI commands:

```
config system admin
  edit admin
    set ssh-public-key1 "<key-type> <key-value>"
  end
```

`<key-type>` must be the `ssh-dss` for a DSA key or `ssh-rsa` for an RSA key. For the `<key-value>`, copy the public key data and paste it into the CLI command.

If you are copying the key data from Windows Notepad, copy one line at a time and ensure that you paste each line of key data at the end of the previously pasted data. Also:

- Do not copy the end-of-line characters that appear as small rectangles in Notepad.
- Do not copy the ---- BEGIN SSH2 PUBLIC KEY ---- or Comment: "[2048-bit dsa,...]" lines.
- Do not copy the ---- END SSH2 PUBLIC KEY ---- line.

4. Type the closing quotation mark and press **Enter**.

Your SCP client can now authenticate to the FortiGate based on SSH keys rather than the administrator password.

### Restoring a configuration using SCP

To restore the configuration using SCP, use the commands:

```
scp <local_file> <admin_user>@<FGT_IP>:fgt-restore-config
```

To use this method of restoring the FortiGate configuration, you need to log in as the "admin" administrator.

### Restore a configuration

Should you need to restore a configuration file, use the following steps:

#### To restore the FortiGate configuration - GUI:

1. Click on **admin** in the upper right-hand corner of the screen and select **Configuration > Restore**.
2. Identify the source of the configuration file to be restored : your **Local PC** or a **USB Disk**.  
The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can restore from the FortiManager using the CLI.
3. Enter the path and file name of the configuration file, or select **Browse** to locate the file.
4. Enter a password if required.
5. Select **Restore**.

#### To restore the FortiGate configuration - CLI:

```
execute restore config management-station normal 0
```

or:

```
execute restore config usb <filename> [<password>]
```

or for FTP, note that port number, username are optional depending on the FTP site:

```
execute restore config ftp <backup_filename> <ftp_server> [<port>] [<user_name>]  
[<password>]
```

or for TFTP:

```
execute restore config tftp <backup_filename> <tftp_server> <password>
```

The FortiGate will load the configuration file and restart. Once the restart has completed, verify that the configuration has been restored.

### Troubleshooting

During the installation, some possible errors may occur, but the solutions are usually straightforward.

Error message	Reason and Solution
Configuration file error	<p>This error occurs when attempting to upload a configuration file that is incompatible with the device. This may be due to the configuration file being for a different model or being saved from a different version of firmware.</p> <p><b>Solution:</b> Upload a configuration file that is for the correct model of FortiGate device and the correct version of the firmware.</p>
Invalid password	<p>When the configuration file is saved, it can be protected by a password. The password entered during the upload process is not matching the one associated with the configuration file.</p> <p><b>Solution:</b> Use the correct password if the file is password protected.</p>

## Configuration revision

You can manage multiple versions of configuration files on models that have a 512MB flash memory and higher. Revision control requires either a configured central management server or the local hard drive, if your FortiGate has this feature. Typically, configuration backup to local drive is not available on lower-end models.

The central management server can either be a FortiManager unit or FortiCloud.

If central management is not configured on your FortiGate unit, a message appears instructing you to either:

- Enable central management, **or**
- obtain a valid license.

When revision control is enabled on your FortiGate unit, and configuration backups have been made, a list of saved revisions of those backed-up configurations appears.

Configuration revisions are viewed by clicking on **admin** in the upper right-hand corner of the screen and selecting **Configuration > Revisions**.

## Restore factory defaults

There may be a need to reset the FortiGate to its original defaults; for example, to begin with a fresh configuration. There are two options when restoring factory defaults. The first resets the entire device to the original out-of-the-box configuration.

You can reset using the CLI by entering the command:

```
execute factoryreset
```

When prompted, type **y** to confirm the reset.

Alternatively, in the CLI you can reset the factory defaults but retain the interface and VDOM configuration. Use the following command:

```
execute factoryreset2
```

## FortiGuard

The FortiGuard Distribution Network (FDN) of servers provides updates to antivirus, antispam, and IPS definitions to your FortiGate. FortiGuard Subscription Services provides comprehensive Unified Threat Management (UTM) security solutions to enable protection against content and network level threats.

The FortiGuard team can be found around the globe, monitoring virus, spyware and vulnerability activities. As vulnerabilities are found, signatures are created and pushed to the subscribed FortiGates. The Global Threat Research Team enables Fortinet to deliver a combination of multi-layered security intelligence and provide true zero-day protection from new and emerging threats. The FortiGuard Network has data centers around the world located in secure, high availability locations that automatically deliver updates to the Fortinet security platforms to protect the network with the latest information.

FortiGuard provides a number of services to monitor world-wide activity and provide the best possible security, including:

- **Intrusion Prevention System (IPS)** - IPS uses a customizable database of more than 4000 known threats to stop attacks that evade conventional firewall defenses. It also provides behavior-based heuristics, enabling the system to recognize threats when no signature has yet been developed. It also provides more than 1000 application identity signatures for complete application control.
- **Application Control** - Application Control allows you to identify and control applications on networks and endpoints regardless of port, protocol, and IP address used. It gives you unmatched visibility and control over application traffic, even traffic from unknown applications and sources. Application Control is a free FortiGuard service and the database for Application Control signatures is separate from the IPS database (Botnet Application signatures are still part of the IPS signature database since these are more closely related with security issues and less about application detection). Application Control signature database information is displayed under the **System > FortiGuard** page in the FortiCare section.

Please note that while the Application Control profile can be used for free, signature database updates require a valid FortiGuard subscription.

---

- **AntiVirus** - The FortiGuard AntiVirus Service provides fully automated updates to ensure protection against the latest content level threats. It employs advanced virus, spyware, and heuristic detection engines to prevent both new and evolving threats from gaining access to your network and protects against vulnerabilities.
- **Web Filtering** - Web Filtering provides Web URL filtering to block access to harmful, inappropriate, and dangerous web sites that may contain phishing/pharming attacks, malware such as spyware, or objectionable content that can expose your organization to legal liability. Based on automatic research tools and targeted research analysis, real-time updates enable you to apply highly-granular policies that filter web access based on six major categories and nearly 80 micro-categories, over 45 million rated web sites, and more than two billion web pages - all continuously updated.
- **Vulnerability Scanning** - FortiGuard Services provide comprehensive and continuous updates for vulnerabilities, remediation, patch scan, and configuration benchmarks.
- **Email Filtering** - The FortiGuard Antispam Service uses both a sender IP reputation database and a spam signature database, along with sophisticated spam filtering tools on Fortinet appliances and agents, to detect and block a wide range of spam messages. Updates to the IP reputation and spam signature databases are provided continuously via the FDN.
- **Messaging Services** - Messaging Services allow a secure email server to be automatically enabled on your FortiGate to send alert email or send email authentication tokens. With the SMS gateway, you can enter phone numbers where the FortiGate will send the SMS messages. Note that depending on your carrier, there may be a slight time delay on receiving messages.
- **DNS and DDNS** - The FortiGuard DNS and DDNS services provide an efficient method of DNS lookups once subscribed to the FortiGuard network. This is the default option. The FortiGate connects automatically to the FortiGuard DNS server. If you do not register, you need to configure an alternate DNS server.

Configure the DDNS server settings using the CLI command:

```
config system fortiguard
  set ddns-server-ip
  set ddns-server-port
end
```

## Support Contract and FortiGuard Subscription Services

The FDN support **Contract** is available under **System > FortiGuard**.

The License Information area displays the status of your FortiGate's support contract.

You can also manually update the AntiVirus and IPS engines.

## Verifying your connection to FortiGuard

If you are not getting FortiGuard web filtering or antispam services, there are a few things to verify that communication to the FDN is working. Before any troubleshooting, ensure that the FortiGate has been registered and subscribed to the FortiGuard services.

### Verification - GUI:

The simplest method to check that the FortiGate is communicating with the FDN, is to check the **License Information** dashboard widget. Any subscribed services should have a green check mark beside them indicating that connections are successful. Any other icon indicates a problem with the connection, or you are not subscribed to the FortiGuard services.

You can also view the FortiGuard connection status by going to **System > FortiGuard**.

### Verification - CLI:

You can also use the CLI to see what FortiGuard servers are available to your FortiGate. Use the following CLI command to ping the FDN for a connection:

```
execute ping guard.fortinet.net
```

You can also use the following diagnose command to find out what FortiGuard servers are available:

```
diagnose debug rating
```

From this command, you will see output similar to the following:

```
Locale : english
License : Contract
Expiration : Sun Jul 24 20:00:00 2011
Hostname : service.fortiguard.net
== Server List (Tue Nov 2 11:12:28 2010) ==
```

IP	Weight	RTT	Flags	TZ	Packets	Curr	Lost	Total	Lost
69.20.236.180	0	10		-5	77200 0		42		
69.20.236.179	0	12		-5	52514	0		34	
66.117.56.42	0	32		-5	34390	0		62	
80.85.69.38	50	164		0	34430	0		11763	
208.91.112.194	81	223	D	-8	42530	0		8129	
216.156.209.26	286	241	DI	-8	55602	0		21555	

An extensive list of servers are available. Should you see a list of three to five available servers, the FortiGuard servers are responding to DNS replies to service FortiGuard.net, but the INIT requests are not reaching FDS services on the servers.

The rating flags indicate the server status:

<b>D</b>	Indicates the server was found via the DNS lookup of the hostname. If the hostname returns more than one IP address, all of them will be flagged with 'D' and will be used first for INIT requests before falling back to the other servers.
<b>I</b>	Indicates the server to which the last INIT request was sent.
<b>F</b>	The server has not responded to requests and is considered to have failed.
<b>T</b>	The server is currently being timed.

The server list is sorted first by weight and then the server with the smallest RTT is put at the top of the list, regardless of weight. When a packet is lost, it will be resent to the next server in the list.

The weight for each server increases with failed packets and decreases with successful packets. To lower the possibility of using a distant server, the weight is not allowed to dip below a base weight, which is calculated as the difference in hours between the FortiGate and the server, multiplied by 10. The further away the server, the higher its base weight and the lower in the list it will appear.

### Port assignment

The FortiGate contacts FDN for the latest list of FDN servers by sending UDP packets with typical source ports of 1027 or 1031, and destination port 8888. The FDN reply packets have a destination port of 1027 or 1031.

If your ISP blocks UDP packets in this port range, the FortiGate cannot receive the FDN reply packets. As a result, the FortiGate will not receive the complete FDN server list.

If your ISP blocks the lower range of UDP ports (around 1024), you can configure your FortiGate to use higher-numbered ports, using the CLI command:

```
config system global
    set ip-src-port-range <start port>--<end port>
end
```

where the <start port> and <end port> are numbers ranging of 1024 to 25000.

For example, you could configure the FortiGate to not use ports lower than 2048 or ports higher than the following range:

```
config system global
    set ip-src-port-range 2048-20000
end
```

Trial and error may be required to select the best source port range. You can also contact your ISP to determine the best range to use. Push updates might be unavailable if:

- there is a NAT device installed between the unit and the FDN, and/or
- your unit connects to the Internet using a proxy server.

### Configuring AntiVirus and IPS Options

Go to **System > FortiGuard**, and scroll down to the **AntiVirus & IPS Updates** section to configure the antivirus and IPS options for connecting and downloading definition files.

<b>Accept push updates</b>	Select to allow updates to be sent automatically to your FortiGate. New definitions will be added as soon as they are released by FortiGuard.
<b>Use override push</b>	<p>Appears only if <b>Accept push updates</b> is enabled.</p> <p>Enable to configure an override server if you cannot connect to the FDN or if your organization provides updates using their own FortiGuard server. Once enabled, enter the following:</p> <ul style="list-style-type: none"> <li>• Enter the IP address and port of the NAT device in front of your FortiGate. FDS will connect to this device when attempting to reach the FortiGate.</li> <li>• The NAT device must be configured to forward the FDS traffic to the FortiGate on UDP port 9443.</li> </ul>
<b>Scheduled Updates</b>	<p>Enable for updates to be sent to your FortiGate at a specific time. For example, to minimize traffic lag times, you can schedule the update to occur on weekends or after work hours.</p> <p>Note that a schedule of once a week means any urgent updates will not be pushed until the scheduled time. However, if there is an urgent update required, select the <b>Update Now</b> button.</p>
<b>Improve IPS quality</b>	Enable to help Fortinet maintain and improve IPS signatures. The information sent to the FortiGuard servers when an attack occurs can be used to keep the database current as variants of attacks evolve.
<b>Use extended IPS signature package</b>	Regular IPS database protects against the latest common and in-the-wild attacks. Extended IPS database includes protection from legacy attacks.
<b>Update AV &amp; IPS Definitions</b>	Select to manually initiate an FDN update.

## Manual updates

To manually update the signature definitions file, you need to first go to the Support web site at <https://support.fortinet.com>. Once logged in, select **Download > FortiGuard Service Updates**. The browser will present you the most current IPS and AntiVirus signature definitions which you can download.

Once downloaded to your computer, log into the FortiGate to load the definition file.

### To load the definition file onto the FortiGate:

1. Go to **System > FortiGuard**.
2. In the **License Information** table, select the **Upgrade Database** link in either the **Application Control Signature**, **IPS**, or **AntiVirus** row.
3. In the pop-up window, select **Upload** and locate the downloaded file and select **Open**.  
The upload may take a few minutes to complete.

## Automatic updates

The FortiGate can be configured to request updates from FDN on a scheduled basis, or via push notification.

## Scheduling updates

Scheduling updates ensures that the virus and IPS definitions are downloaded to your FortiGate on a regular basis, ensuring that you do not forget to check for the definition files yourself.

Updating definitions can cause a very short disruption in traffic currently being scanned while the FortiGate unit applies the new signature database. Ideally, schedule updates during off-peak hours, such as evenings or weekends, when network usage is minimal, to ensure that the network activity will not suffer from the added traffic of downloading the definition files.

### To enable scheduled updates - GUI:

1. Go to **System > FortiGuard** and scroll down to **AntiVirus & IPS Updates**.
2. Enable **Scheduled Updates**.
3. Select the frequency of updates.
4. Select **Apply**.

### To enable scheduled updates - CLI:

```
config system autoupdate schedule
  set status enable
  set frequency {every | daily | weekly}
  set time <hh:mm>
  set day <day_of_week>
end
```

## Push updates

Push updates enable you to get immediate updates when new viruses or intrusions have been discovered and new signatures created. This ensures that the latest signature will be sent to the FortiGate as soon as possible.

When a push notification occurs, the FortiGuard server sends a notice to the FortiGate that there is a new signature definition file available. The FortiGate then initiates a download of the definition file, similar to the scheduled update.

To ensure maximum security for your network, you should have a scheduled update as well as enable the push update, in case an urgent signature is created, and your cycle of the updates only occurs weekly.

### To enable push updates - GUI:

1. Go to **System > FortiGuard** and scroll down to **AntiVirus & IPS Updates**.
2. Enable **Accept push updates**.
3. Select **Apply**.

### To enable push updates - CLI:

```
config system autoupdate push-update
  set status enable
end
```

## Push IP override

If the FortiGate is behind another NAT device (or another FortiGate), to ensure it receives the push update notifications, you need to use an override IP address for the notifications. To do this, you create a virtual IP to map to the external port of the NAT device.

Generally speaking, if there are two FortiGate devices, the following steps need to be completed on the FortiGate NAT device to ensure the FortiGate on the internal network receives the updates:

- Add a port forwarding virtual IP to the FortiGate NAT device that connects to the Internet by going to **Policy & Objects > Virtual IPs**.
- Add a security policy to the FortiGate NAT device that connects to the Internet that includes the port forwarding virtual IP.
- Configure the FortiGate on the internal network with an override push IP and port.

On the FortiGate internal device, the virtual IP is entered as the **Use push override** IP address.

### To enable push update override- GUI:

1. Go to **System > FortiGuard** and scroll down to **AntiVirus & IPS Updates**.
2. Enable **Accept push updates**.
3. Enable **Use override push**.
4. Enter the virtual IP address configured on the NAT device.
5. Select **Apply**.

### To enable push updates - CLI:

```
config system autoupdate push-update
    set status enable
    set override enable
    set address <vip_address>
end
```

## Sending malware statistics to FortiGuard

To support following malware trends and making zero-day discoveries, FortiGate units send encrypted statistics to FortiGuard about IPS, Application Control, and AntiVirus events detected by the FortiGuard services running on your FortiGate. FortiGuard uses the statistics collected to achieve a balance between performance and security effectiveness by moving inactive signatures to an extended signature database.

The statistics include some non-personal information that identifies your FortiGate and its country. The information is never shared with external parties. You can choose to disable the sharing of this information by entering the following CLI command:

```
config system global
    set fds-statistics disable
end
```

## Configuring Web Filtering and Email Filtering Options

Go to **System > FortiGuard**, and scroll down to **Filtering** to set the size of the caches and ports.

<b>Web Filter Cache</b>	Set the Time To Live (TTL) value. This is the number of seconds the FortiGate will store a blocked IP or URL locally, saving time and network access traffic, checking the FortiGuard server. Once the TTL has expired, the FortiGate will contact an FDN server to verify a web address. The TTL must be between 300 and 86400 seconds.
<b>Anti-Spam Cache</b>	Set the TTL value (see above).
<b>FortiGuard Filtering Port</b>	Select the port assignments for contacting the FortiGuard servers.
<b>Filtering Service Availability</b>	Indicates the status of the filtering service. Select <b>Check Again</b> if the filtering service is not available.
<b>Request re-evaluation of a URL's category</b>	Select to re-evaluate a URL's category rating on the FortiGuard Web Filter service.

## Email filtering

The FortiGuard data centers monitor and update email databases of known spam sources. With FortiGuard Anti-Spam filtering enabled, the FortiGate verifies incoming email sender addresses and IPs against the database, and takes the necessary actions as defined within the antivirus profiles.

Spam source IP addresses can also be cached locally on the FortiGate, providing a quicker response time, while easing load on the FortiGuard servers, aiding in a quicker response time for less common email address requests.

By default, the anti-spam cache is enabled. The cache includes a TTL value, which is the amount of time an email address will stay in the cache before expiring. You can change this value to shorten or extend the time between 5 and 1,440 minutes.

### To modify the antispam cache TTL - GUI:

1. Go to **System > FortiGuard**.
2. Under **Filtering**, enable **Anti-Spam Cache**.
3. Enter the TTL value in minutes.
4. Select **Apply**.

### To modify the Anti-Spam filter TTL - CLI:

```
config system fortiguard
    set antispam-cache-ttl <integer>
end
```

Further antispam filtering options can be configured to block, allow, or quarantine specific email addresses. These configurations are available through the **Security Profiles > Anti-Spam** menu. For more information, see the [Security Profiles](#) handbook chapter.

## Online Security Tools

The FortiGuard online center provides a number of online security tools, including but not limited to:

- **URL lookup** — By entering a website address, you can see if it has been rated and what category and classification it is filed as. If you find your website or a site you commonly go to has been wrongly categorized, you can use this page to request that the site be re-evaluated.  
<https://fortiguard.com/webfilter>
- **Threat Encyclopedia** — Browse the Fortiguard Labs extensive encyclopedia of threats. Search for viruses, botnet C&C, IPS, endpoint vulnerabilities, and mobile malware.  
<https://www.fortiguard.com/encyclopedia>
- **Application Control** — Browse the Fortiguard Labs extensive encyclopedia of applications.  
<https://fortiguard.com/appcontrol>

## FortiCloud

FortiCloud is a hosted security management and log retention service for FortiGate devices. It gives you centralized reporting, traffic analysis, configuration management, and log retention without the need for additional hardware or software.

FortiCloud offers a wide range of features:

- **Simplified central management** — FortiCloud provides a central web-based management console to manage individual or aggregated FortiGate and FortiWiFi devices. Adding a device to the FortiCloud management subscription is straightforward. FortiCloud has detailed traffic and application visibility across the whole network.
- **Hosted log retention with large default storage allocated** — Log retention is an integral part of any security and compliance program but administering a separate storage system is burdensome. FortiCloud takes care of this automatically and stores the valuable log information in the cloud. Each device is allowed up to 200GB of log retention storage. Different types of logs can be stored including Traffic, System Events, Web, Applications, and Security Events.
- **Monitoring and alerting in real time** — Network availability is critical to a good end-user experience. FortiCloud enables you to monitor your FortiGate network in real time with different alerting mechanisms to pinpoint potential issues. Alerting mechanisms can be delivered via email.
- **Customized or pre-configured reporting and analysis tools** — Reporting and analysis are your eyes and ears into your network's health and security. Pre-configured reports are available, as well as custom reports that can be tailored to your specific reporting and compliance requirements. For example, you may want to look closely at application usage or website violations. The reports can be emailed as PDFs and can cover different time periods.
- **Maintain important configuration information uniformly** — The correct configuration of the devices within your network is essential to maintaining an optimum performance and security posture. In addition, maintaining the correct firmware (operating system) level allows you to take advantage of the latest features.
- **Service security** — All communication (including log information) between the devices and the clouds is encrypted. Redundant data centers are always used to give the service high availability. Operational security measures have been put in place to make sure your data is secure — only you can view or retrieve it.

## Registration and Activation

Before you can activate a FortiCloud account, you must first register your device.

FortiCloud accounts can be registered manually through the FortiCloud website, <https://www.forticloud.com>, but you can easily register and activate your account directly from your FortiGate.

## Activating your FortiCloud Account

1. On your device's dashboard, in the **FortiCloud** widget, select the **Activate** button in the status field.
2. A dialogue asking you to register your FortiCloud account appears. Select **Create Account**, enter your information, view and accept the terms and conditions, and select **OK**.
3. A second dialogue window appears, asking you to enter your information to confirm your account. This sends a confirmation email to your registered email. The dashboard widget then updates to show that confirmation is required.
4. Open your email, and follow the confirmation link it contains.

## Results

A FortiCloud page will open, stating that your account has been confirmed. The Activation Pending message on the dashboard will change to state the type of account you have ('1GB Free' or '200GB Subscription'), and will provide a link to the FortiCloud portal.

## Enabling logging to FortiCloud

1. Go to **Log & Report > Log Settings**.
2. Enable **Send Logs to FortiCloud**.
3. Select **Test Connectivity** to ensure that your FortiGate can connect to the registered FortiCloud account.
4. Scroll down to **GUI Preferences**, set **Display Logs/FortiView From**, to see FortiCloud logs within the FortiGate's GUI.

## Logging into the FortiCloud portal

Once logging has been configured and you have registered your account, you can log into the FortiCloud portal and begin viewing your logging results. There are two methods to reach the FortiCloud portal:

- If you have direct networked access to the FortiGate, you can simply open your **Dashboard** and check the **License Information** widget. Next to the current FortiCloud connection status will be a link to reach the FortiCloud Portal.
- If you do not currently have access to the FortiGate's interface, you can visit the FortiCloud website (<https://forticloud.com>) and log in remotely, using your email and password. It will ask you to confirm the FortiCloud account you are connecting to and then you will be granted access. Connected devices can be remotely configured using the Scripts page in the Management Tab, useful if an administrator may be away from the unit for a long period of time.

## Cloud Sandboxing

FortiCloud can be used for automated sample tracking, or sandboxing, for files from a FortiGate. This allows suspicious files to be sent to be inspected without risking network security. If the file exhibits risky behavior, or is found to contain a virus, a new virus signature is created and added to the FortiGuard antivirus signature database.

Cloud sandboxing is configured by going to **Security Fabric > Settings**. After enabling **Sandbox Inspection**, select the **FortiSandbox type**.

Sandboxing results are shown in a new tab called **AV Submissions** in the FortiCloud portal. This tab only appears after a file has been sent for sandboxing.

For more information about FortiCloud, see the [FortiCloud documentation](#).

## Troubleshooting your FortiGate Installation

If your FortiGate does not function as desired after installation, try the following troubleshooting tips:

**1. Use FortiExplorer if you can't connect to the FortiGate over Ethernet**

If you can't connect to the FortiGate GUI or CLI, you may be able to connect using FortiExplorer. Refer to the QuickStart Guide or see the section on the [FortiExplorer](#) for more details.

**2. Check for equipment issues**

Verify that all network equipment is powered on and operating as expected. Refer to the QuickStart Guide for information about connecting your FortiGate to the network. You will also find detailed information about the FortiGate LED indicators.

**3. Check the physical network connections**

Check the cables used for all physical connections to ensure that they are fully connected and do not appear damaged, and make sure that each cable connects to the correct device and the correct Ethernet port on that device.

**4. Verify that you can connect to the internal IP address of the FortiGate**

Connect to the GUI from the FortiGate's internal interface by browsing to its IP address. From the PC, try to ping the internal interface IP address; for example, `ping 192.168.1.99`.

If you cannot connect to the internal interface, verify the IP configuration of the PC. If you can ping the interface but can't connect to the GUI, check the settings for administrative access on that interface.

**5. Check the FortiGate interface configurations**

Check the configuration of the FortiGate interface connected to the internal network by going to **Network > Interfaces** and make sure **Addressing mode** is set to the correct mode.

**6. Verify the security policy configuration**

Go to **Policy & Objects > IPv4 Policy** and verify that the internal interface to Internet-facing interface security policy has been added and is located near the top of the policy list. Check the **Active Sessions** column to ensure that traffic has been processed (if this column does not appear, right-click on the title row, select **Active Sessions**).

If you are using NAT/Route mode, check the configuration of the policy to make sure that **NAT** is enabled and that **Use Outgoing Interface Address** is selected.

**7. Verify that you can connect to the Internet-facing interface's IP address**

Ping the IP address of the FortiGate's Internet-facing interface. If you cannot connect to the interface, the FortiGate is not allowing sessions from the internal interface to Internet-facing interface.

**8. Verify the static routing configuration**

Go to **Network > Static Routes** and verify that the default route is correct. Go to **Monitor > Routing Monitor** and verify that the default route appears in the list as a static route. Along with the default route, you should see two routes shown as **Connected**, one for each connected FortiGate interface.

**9. Verify that you can connect to the gateway provided by your ISP**

Ping the default gateway IP address from a PC on the internal network. If you cannot reach the gateway, contact your ISP to verify that you are using the correct gateway.

**10. Verify that you can communicate from the FortiGate to the Internet**

Access the FortiGate CLI and use the command `execute ping 8.8.8.8`. You can also use the `execute traceroute 8.8.8.8` command to troubleshoot connectivity to the Internet.

**11. Verify the DNS configurations of the FortiGate and the PCs**

Check for DNS errors by pinging or using traceroute to connect to a domain name; for example: `ping www.fortinet.com`.

If the name cannot be resolved, the FortiGate or PC cannot connect to a DNS server and you should confirm that the DNS server IP addresses are present and correct.

**12. Confirm that the FortiGate can connect to the FortiGuard network**

Once registered, the FortiGate obtains AntiVirus and Application Control and other updates from the FortiGuard network. Once the FortiGate is on your network, you should confirm that it can reach the FortiGuard network. First, check the **License Information** widget to make sure that the status of all FortiGuard services matches the services that you have purchased.

Go to **System > FortiGuard**. Scroll down to **Filtering Services Availability** and select **Check Again**. After a minute, the GUI should indicate a successful connection.

**13. Consider changing the MAC address of your external interface**

Some ISPs do not want the MAC address of the device connecting to their network cable to change. If you have added a FortiGate to your network, you may have to change the MAC address of the Internet-facing interface using the following CLI command:

```
config system interface
  edit <interface>
    set macaddr <xx:xx:xx:xx:xx:xx>
  end
end
```

**14. Either reset the FortiGate to factory defaults or contact Fortinet Support for assistance. See the note below before contacting support.**

To reset the FortiGate to factory defaults, use the CLI command `execute factoryreset`. When prompted, type `y` to confirm the reset.

You can also contact Fortinet Support for assistance. Read the following article found on the Fortinet Cookbook website: [How to work with Fortinet Support](#) to understand what type of support is available and to determine which level of support is right for you. For further information, go to [support.fortinet.com](https://support.fortinet.com).

## Resources

Here's a list of some resources you can check out next to help you get the most out of your newly installed and configured FortiGate.

### Best Practices

The Best Practices document is a collection of guidelines to ensure the most secure and reliable operation of FortiGates in a customer environment. It is updated periodically as new issues are identified.

This document can be found at <http://docs.fortinet.com/>.

### The Fortinet Cookbook

The Fortinet Cookbook contains a variety of step-by-step examples of how to integrate a FortiGate into your network and apply features such as security profiles, wireless networking, and VPN.

Using the Cookbook, you can go from idea to execution in simple steps, configuring a secure network for better productivity with reduced risk.

The Fortinet Cookbook can be found at <http://cookbook.fortinet.com>.

### The Fortinet Video Library

The Fortinet Video Library contains video tutorials showing how to configure various Fortinet products, including FortiGates. Many FortiGate videos are based on recipes from the FortiGate Cookbook.

The Fortinet Video Library can be found at <http://video.fortinet.com>. You can also [subscribe to Fortinet's YouTube channel](#).

### The FortiOS Handbook

The FortiOS Handbook is the complete guide to FortiOS, covering a variety of FortiGate configurations. The Handbook is available as a single complete document online. Handbook chapters are also available as standalone documents.

The FortiOS Handbook can be found at <http://docs.fortinet.com/>.

# Chapter 3 - Authentication

This Handbook chapter contains the following sections:

[Introduction to authentication](#) describes some basic elements and concepts of authentication.

[Authentication servers](#) describes external authentication servers, where a FortiGate unit fits into the topology, and how to configure a FortiGate unit to work with that type of authentication server.

[Users and user groups](#) describes the different types of user accounts and user groups. Authenticated access to resources is based on user identities and user group membership. Two-factor authentication methods, including FortiToken, provide additional security.

[Managing Guest Access](#) explains how to manage temporary accounts for visitors to your premises.

[Configuring authenticated access](#) provides detailed procedures for setting up authenticated access in security policies and authenticated access to VPNs.

[Captive portals](#) describes how to authenticate users through a web page that the FortiGate unit presents in response to any HTTP request until valid credentials are entered. This can be used for wired or WiFi network interfaces.

[Certificate-based authentication](#) describes authentication by means of X.509 certificates.

[Single Sign-On using a FortiAuthenticator unit](#) describes how to use a FortiAuthenticator unit as an SSO agent that can integrate with external network authentication systems such as RADIUS and LDAP to gather user logon information and send it to the FortiGate unit. Users can also log on through a FortiAuthenticator-based web portal or the FortiClient SSO Mobility Agent.

[Single Sign-On to Windows AD](#) describes how to set up Single Sign-On in a Windows AD network by configuring the FortiGate unit to poll domain controllers for information user logons and user privileges.

[Agent-based FSSO](#) describes how to set up Single Sign-On in Windows AD, Citrix, or Novell networks by installing Fortinet Single Sign On (FSSO) agents on domain controllers. The FortiGate unit receives information about user logons and allows access to network resources based on user group memberships.

[SSO using RADIUS accounting records](#) describes how to set up Single Sign-On in a network that uses RADIUS authentication. In this configuration, the RADIUS server send RADIUS accounting records to the FortiGate unit when users log on or off the network. The record includes a user group name that can be used in FortiGate security policies to determine which resources each user can access.

[Monitoring authenticated users](#) describes FortiOS authenticated user monitor screens.

[Examples and Troubleshooting](#) provides configuration examples and troubleshooting suggestions.

## Whats new in FortiOS 5.6

This chapter describes new authentication features added to FortiOS 5.6.

### FortiOS 5.6.4

These features first appeared in FortiOS 5.6.4.

- "Authentication binds to MAC address" on page 377
- "RADIUS accounting start message options" on page 389
- "IPv6 TACACS+ server IP address" on page 402
- "Login credentials for guest users shown in clear text on GUI and voucher" on page 424

### FortiOS 5.6.3

These features first appeared in FortiOS 5.6.3.

#### Certificate Import page updates (267949)

The importation of a non-CA certificate into FortiGate CA store now shows a warning message showing why the import didn't work (as expected).

#### Improvements to the execute fortitoken import command (401979)

The `execute fortitoken import` command has been removed and replaced by three new commands, allowing the importation of FortiToken seed files from either an FTP server, a TFTP server, or a USB drive:

- `execute fortitoken import ftp <file name> <ip>[:ftp port] <Enter> <user> <password>`
- `execute fortitoken import tftp <file name> <ip>`
- `execute fortitoken import usb <file name>`

These commands allow seed files to be imported from an external source more easily.

#### Improved 2FA workflow in GUI (405487, 409100, 444430, 446856, 456752)

Various improvements to the two-factor authentication workflow in the GUI which addressed the following issues:

- No email was sent after creating an administrator account with a FortiToken.
- Inconsistent view on admin and user dialog.
- Empty activation codes would be sent.
- If Norway was selected as the country code for a user, the phone number was not recognized after saving.
- Couldn't select custom SMS server when setting the phone number.
- When a FortiToken from a non-management VDOM was selected for an admin, the activation code wouldn't be sent.

### Support FTM Push when FortiAuthenticator is the authentication server (408273, 438314)

FortiGate supports when the FortiAuthenticator initiates FTM Push notifications, for when users are attempting to authenticate through a VPN and/or RADIUS (with FortiAuthenticator as the RADIUS server).

### Support exact match for subject and CN fields in peer user (416359)

Administrators can now specify which way a peer user authenticates, in order to avoid any unintentional admin access by a regular user. When searching for a matching certificate, use the commands below to control how to find matches in the certificate subject name (`subject-match`) or the cn attribute (`cn-match`) of the certificate subject name. This match can be any string (`substring`) or an exact match (`value`) of the cn attribute value.

#### Syntax

```
config vpn certificate setting
  edit <name>
    set subject-match {substring | value}
    set cn-match {substring | value}
  next
end
```

### FortiToken GUI improvement (435229)

Various FortiToken import functionalities have been improved in the GUI, including the ability to import from serial number file correctly, validation of serial numbers once imported, and removing the Activate button once a token has already been activated.

### Improve FTM Push notification workflow (436642, 448734)

Updated GUI and logincheck module to use a non-blocking version of the FTM Push notification procedure and periodically polls the device for any status updates from fam daemon.

### FortiClient shares Social ID data with FortiOS (438610)

Support has been added to record the social ID data from FortiClient so that if an email or phone number is changed on FortiClient, the new values are updated on the FortiGate.

The data will be sent in KeepAlive messages in the following format:

```
USR_NAME|<full name for the service account>|USR_EMAIL|<email for the service account>|SERVICE|<os|custom|linkedin|google|salesforce>|
```

### Wildcard certificate support/handling for SAN/CN reference identifiers (440307)

As a requirement of Network Device Collaborative Protection Profile (NDcPP), FortiOS supports and handles the use of wildcards for the following certificate reference parameters:

- Subject Alternative Name (SAN)
- Common Name (CN)

### Support for FTP and TFTP to update certificates (441695)

Support has been added for FTP and TFTP servers to update the certificate bundle using a new `execute` command.

**Syntax**

```
execute vpn certificate ca import bundle <file-name.pkg> <ftp/tftp-server-ip>
```

**Global option to enable/disable SHA1 algorithm in SSH key exchanges (444827)**

Support has been added for a global option to enable/disable SHA1 algorithm in SSH key exchanges. The algorithm is enabled by default and provides administrators with the ability to disable the option for the purposes of security and compliance testing.

**Syntax**

```
config system global
    set ssh-kex-shal {enable | disable}
end
```

**Support for HTTP tunnel authentication (449406)**

Support has been added for an option to trigger user authentication on HTTP CONNECT request at the policy level. A new CLI entry has been added under `config firewall proxy-policy` which will trigger the authentication process `get-user`, even when there is no user or group configured.

Note that, as shown below, explicit web proxy must be set.

**Syntax**

```
config firewall proxy-policy
    edit {policyid}
        set proxy explicit-web
        set http-tunnel-auth {enable | disable}
    next
end
```

**FortiOS 5.6.1**

These features first appeared in FortiOS 5.6.1.

**IPv6 RADIUS Support (309235, 402437, 439773)**

RADIUS authentication is supported with IPv6, allowing administrators to configure an IPv6 RADIUS server on the FortiGate for IPv6 RADIUS authentication traffic to pass between the server and FortiGate.

Note that while you can set the primary RADIUS server's IPv6 address, the source IP address for communications to the RADIUS server cannot be configured as IPv6.

**Syntax**

Allow IPv6 access on an interface:

```
config system interface
    edit <name>
        config ipv6
            set ip6-allowaccess {ping | https | ssh | snmp | http | telnet | fgfm | capwap}
            set ip6-address <xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx/xxx>
```

```
    next
  next
end
```

Configure the IPv6 RADIUS server:

```
config user radius
  edit <name>
    set server <xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx>
    ...
  next
end
```

### Full certificate chain CRL checking (407988)

Certificate revocation/status check for peer certificates and intermediate CAs is now supported. Redesigned `fnbam_auth_cert()` API to use stack type of X509 instead of array for certificate chain. Removed obsolete `fnbam` API and parameters. Now `authd`, `sslvpn`, and GUI send full certificate chains to `fnbamd` for verification.

### New option under `user > setting` to allow/forbid SSL renegotiation in firewall authentication (386595)

A new option `auth-ssl-allow-renegotiation` is now available under `config user setting` to allow/forbid renegotiation. The default value is `disable`, where a session would be terminated by `authd` once renegotiation is detected and this login would be recorded as failure. Other behavior follows regular auth settings.

#### Syntax

```
config user setting
  set auth-ssl-allow-renegotiation {enable | disable}
end
```

### New option to allow spaces in RADIUS DN format (422978)

Previously, IKEv2 RADIUS group authentication introduced a regression because it removed spaces from ASN.1 DN peer identifier string.

Reverted default DN format to include spaces. Added a new CLI option `ike-dn-format` to allow the user to select either `with-space` or `no-space`. Customers using the `group-authentication` option can select the `ike-dn-format` setting to match the format used in their RADIUS user database.

### Added LDAP filter when `group-member-check` is `user-attr` (403140)

Added LDAP filter when `group-member-check` is `user-attr`. LDAP filter is deployed when checking user attribute.

#### Syntax

```
config user ldap
  edit <name>
    set group-filter ?
  next
end
```

- `group-filter` is `none` by default, where the process is the same as before.  
When `group-filter` is set, the LDAP filter takes effect for retrieving the group information.

## Added Refresh button to the LDAP browser (416649)

Previously, cached LDAP data was used even if the LDAP server configuration was updated.

In FortiOS 5.6.1, a **Refresh** button has been added in the LDAP browser. In the LDAP server dialog page, the user can delete the DN field to browse the root level tree when clicking the **Fetch DN** button.

## Differentiate DN option for user authentication and membership searching (435791)

Previously, LDAP used the same DN option for user authentication and membership searching. New CLI commands are introduced to `config user ldap` to resolve this issue:

- `group-member-check user-attr`  
For user attribute checking, a new attribute `group-search-base` is added, which indicates the starting point for the group search. If the `group-search-base` is not set, `binddn` is used as the search base. Removed `search-type` when `group-member-check` is `user-attr`.
- `group-member-check group-object`  
For group object checking, the group names in user group match rule will be picked up as the group search base. If there are multiple matching rules, each group name will trigger the `ldapsearch` query once.
- `group-member-check posix-group-object`  
Changed `group-object-search-base` to `group-search-base` for `posix-group-object` `group-member-check`.

## FTM Push when FAC is auth server (408273)

This feature adds support for FortiToken Mobile (FTM) push with FortiAuthenticator server in FortiOS. It also fixes a crash when adding a node to an RB tree, by checking if the same key has already been used in the tree. If yes, remove the node using the same key before adding a new node.

## Non-blocking LDAP authentication (433700)

The previous LDAP authentication in `fnbamd` used `openldap` library. `OpenLDAP` supports non-blocking BIND but it is not event driven.

To support non-blocking LDAP in `fnbamd`, we stopped using the `openLDAP` library in `fnbamd`, instead using only `liblber`. Instead of using `openLDAP`, `fnbamd` will create its own event-driven connection with LDAP servers over `LDAP/LDAPS/STARTTLS`, make it non-blocking, do CRL checking if necessary, and compose all LDAP requests using `liblber` (including `bind`, `unbind`, `search`, `password renewal`, `password query`, `send request` and `receive response`, and `parse response`). The whole process is done in one connection.

This doesn't change any `openLDAP` implementation but moves some data structure definitions and API definitions from some internal header files to public header files.

## Manual certificate SCEP renewal (423997)

Added support of manual certificate SCEP renewal besides the auto-regeneration feature that already exists.

## More detailed RADIUS responses shown in connectivity test (434303)

Improved on-demand test connectivity for RADIUS servers. Test results show RADIUS server reachability, NAS client rejection, and invalid User/Password. Test also shows RADIUS Attributes returned from the RADIUS server.

### Example

```
FG100D3G12807101 # diagnose test authserver radius-direct
<server_name or IP> <port no(0 default port)> <secret> <user> <password>

FG100D3G12807101 # diagnose test authserver radius-direct 1.1.1.1 0 dd
RADIUS server '1.1.1.1' status is Server unreachable

FG100D3G12807101 # diagnose test authserver radius-direct 172.18.5.28 0 dd
RADIUS server '172.18.5.28' status is Secret invalid

FG100D3G12807101 # diagnose test authserver radius-direct 172.18.5.28 0 fortinet jeff1
asdfasdf
RADIUS server '172.18.5.28' status is OK
Access-Reject

FG100D3G12807101 # diagnose test authserver radius-direct 172.18.5.28 0 fortinet ychen1
asdfasdf
RADIUS server '172.18.5.28' status is OK
Access-Accept
AVP: l=6 t=Framed-Protocol(7)
  Value: 1
AVP: l=6 t=Service-Type(6)
  Value: 2
AVP: l=46 t=Class(25)
  Value: 9e 2a 08 6d 00 00 01 37 00 01 17 00 fe 80 00 00 00 00 00 00 00 00 5e fe ac 12 05
    1c 01 d2 cd b6 75 a6 80 56 00 00 00 00 00 00 00 1c
AVP: l=12 t=Vendor-Specific(26) v=Microsoft(311)
  VSA: l=6 t=MS-Link-Utilization-Threshold(14)
  Value: 50
AVP: l=12 t=Vendor-Specific(26) v=Microsoft(311)
  VSA: l=6 t=MS-Link-Drop-Time-Limit(15)
  Value: 120
```

### User group authentication timeout range increased to 30 days (378085)

You can now use the following command to override the default user authentication timeout for users in a user group to up to 30 days.

```
config user group
  edit <group-name>
    set authtimeout 43200
  end
```

Where `authtimeout` is the length of the timeout in minutes. An `authtimeout` of 43200 minutes is equivalent to 30 days. Set `authtimeout` to 0 to use the default authentication timeout.

## FortiOS 5.6.0

These features first appeared in FortiOS 5.6.0.

### FortiToken Mobile Push (397912, 408273, 399839, 404872)

FortiToken Mobile push supports two-factor authentication without requiring users to enter a four-digit code to authenticate. Instead they can just accept the authentication request from their FortiToken Mobile app.

A new command has been added under `config system ftm-push` allowing you to configure the FortiToken Mobile Push services server IP address and port number. The Push service is provided by Apple (APNS) and Google (GCM) for iPhone and Android smartphones respectively. This will help to avoid tokens becoming locked after an already enabled two-factor authentication user has been disabled.

### CLI syntax

```
config system ftm-push
  set server-ip <ip-address>
  set server-port [1-65535] Default is 4433.
end
```

If an SSL VPN user authenticates with their token, then logs out and attempts to reauthenticate again within a minute, a new message will display showing "Please wait x seconds to login again." This replaces a previous error/permission denied message.

The "x" value will depend on the calculation of how much time is left in the current time step.

### CLI syntax

```
config system interface
  edit <name>
    set allowaccess ftm
  next
end
```

## Support V4 BIOS certificate (392960)

FortiOS now supports backwards compatibility between new BIOS version 4 and old BIOS version 3.

### New BIOS V4 certificates:

- Fortinet\_CA
- Fortinet\_Sub\_CA
- Fortinet\_Factory

### Old BIOS V3 certificates:

- Fortinet\_CA\_Backup
- Fortinet\_Factory\_Backup

When FortiOS connects to FortiGuard, FortiCloud, FortiManager, FortiAnalyzer, FortiSandbox as a client, the new BIOS certificate **Fortinet\_Factory** will be the default client certificate. When the server returns its certificate (chain) back, FortiOS looks up the issuer of the server certificate and either keeps client certificate as is or switches to the old BIOS certificate **Fortinet\_Factory\_Backup**. This process occurs in one handshake.

When FortiOS connects to FortiCare, the new BIOS certificate **Fortinet\_Factory** is the only client certificate and Server Name Indication (SNI) is set. There is no switchover of certificate during SSL handshake.

When FortiOS acts as a server when connected by FortiExtender, FortiSwitch, FortiAP, etc., **Fortinet\_Factory** is the default server certificate. FortiOS detects SNI in client hello, and if no SNI is found or if the CN in SNI is different from the CN of **Fortinet\_CA**, it switches to use the old **Fortinet\_Factory\_Backup**.

### Support extendedKeyUsage for x.509 certificates (390393)

As per Network Device Collaborative Protection Profile (NDcPP) v1.0 requirements, server certificates used for TLS connections between FortiGate and FortiAnalyzer should have the "Server Authentication" and "Client Authentication" extendedKeyUsage fields in FIPS/CC mode.

To implement this, a new CLI command has been added under `log fortianalyzer setting` to allow you to specify the certificate used to communicate with FortiAnalyzer.

#### CLI syntax

```
config log fortianalyzer setting
    set certificate <name>
end
```

### Administrator name added to system event log (386395)

The administrator's name now appears in the system event log when the admin issues a user quarantine ban on a source address.

### Support RSA-4096 bit key-length generation (380278)

In anticipation of quantum computers, RSA-4096 bit key-length CSRs can now be imported.

### New commands added to config user ldap to set UPN processing method and filter name (383561)

Added two new commands to `config user ldap` allowing you to keep or strip domain string of UPN in the token as well as the search name for this kind of UPN.

#### CLI syntax:

```
config user ldap
    set account-key-processing
    set account-key-name
end
```

### User authentication max timeout setting change (378085)

To accommodate wireless hotspot users authenticated on the FortiGate, the user authentication max timeout setting has been extended to three days (from one day, previously).

### Changes to Authentication Settings > Certificates GUI (374980)

Added new icons for certificate types and updated formatters to use these new icons.

### Password for private key configurable in both GUI and CLI (374593)

FortiOS 5.4.1 introduced a feature that allowed you to export a local certificate and its private key in password protected p12, and later import them to any device. This option to set password for private key was available only in the CLI (when requesting a new certificate via SCEP or generating a CSR). This feature is now also configurable through the GUI.

The new **Password for private key** option is available under **System > Certificates** when generating a new CSR.

### RADIUS password encoding (365145)

A new CLI command, under `config user radius`, has been added to allow you to configure RADIUS password encoding to use ISO-8859-1 (as per [RFC 2865](#)).

Certain RADIUS servers use ISO-8859-1 password encoding instead of others such as UTF-8. In these instances, the server will fail to authenticate the user, if the user's password is using UTF-8.

#### CLI syntax

```
config user radius
  edit <example>
    set password-encoding <auto | ISO-8859-1>
  end
```

This option will be skipped if the `auth-type` is neither `auto` nor `pap`.

### RSSO supports Delegated-IPv6-Prefix and Framed-IPv6-Prefix (290990)

Two attributes, **Delegated-IPv6-Prefix** and **Framed-IPv6-Prefix**, have been introduced for RSSO to provide a /56 prefix for DSL customers. All devices connected from the same location (/56 per subscriber) can be mapped to the same profile without the need to create multiple /64 or smaller entries.

## Introduction to authentication

Identifying users and other computers—authentication—is a key part of network security. This section describes some basic elements and concepts of authentication.

The following topics are included in this section:

- [What is authentication?](#)
- [Methods of authentication](#)
- [Types of authentication](#)
- [User's view of authentication](#)
- [FortiGate administrator's view of authentication](#)

## What is authentication?

Businesses need to authenticate people who have access to company resources. In the physical world this may be a swipe card to enter the building, or a code to enter a locked door. If a person has this swipe card or code, they have been authenticated as someone allowed in that building or room.

Authentication is the act of confirming the identity of a person or other entity. In the context of a private computer network, the identities of users or host computers must be established to ensure that only authorized parties can access the network. The FortiGate unit enables controlled network access and applies authentication to users of security policies and VPN clients.

## Methods of authentication

FortiGate unit authentication is divided into three basic types: password authentication for people, certificate authentication for hosts or endpoints, and two-factor authentication for additional security beyond just passwords. An exception to this is that FortiGate units in an HA cluster and FortiManager units use password authentication.

Password authentication verifies individual user identities, but access to network resources is based on membership in user groups. For example, a security policy can be configured to permit access only to the members of one or more user groups. Any user who attempts to access the network through that policy is then authenticated through a request for their username and password.

Methods of authentication include:

- [Local password authentication](#)
- [Server-based password authentication](#)
- [Certificate-based authentication](#)
- [Two-factor authentication](#)

## Local password authentication

The simplest authentication is based on user accounts stored locally on the FortiGate unit. For each account, a username and password is stored. The account also has a disable option so that you can suspend the account without deleting it.

Local user accounts work well for a single-FortiGate installation. If your network has multiple FortiGate units that will use the same accounts, the use of an external authentication server can simplify account configuration and maintenance.

You can create local user accounts in the web-based manager under **User & Device > User Definition**. This page is also used to create accounts where an external authentication server stores and verifies the password.

## Server-based password authentication

Using external authentication servers is desirable when multiple FortiGate units need to authenticate the same users, or where the FortiGate unit is added to a network that already contains an authentication server. FortiOS supports the use of LDAP, RADIUS, TACACS+, AD or POP3 servers for authentication.

When you use an external authentication server to authenticate users, the FortiGate unit sends the user's entered credentials to the external server. The password is encrypted. The server's response indicates whether the supplied credentials are valid or not.

You must configure the FortiGate unit to access the external authentication servers that you want to use. The configuration includes the parameters that authenticate the FortiGate unit to the authentication server.

You can use external authentication servers in two ways:

- Create user accounts on the FortiGate unit, but instead of storing each user's password, specify the server used to authenticate that user. As with accounts that store the password locally, you add these users to appropriate user groups.
- Add the authentication server to user groups. Any user who has an account on the server can be authenticated and have the access privileges of the FortiGate user group. Optionally, when an LDAP server is a FortiGate user group member, you can limit access to users who belong to specific groups defined on the LDAP server.

## Certificate-based authentication

An RSA X.509 server certificate is a small file issued by a Certificate Authority (CA) that is installed on a computer or FortiGate unit to authenticate itself to other devices on the network. When one party on a network presents the certificate as authentication, the other party can validate that the certificate was issued by the CA. The identification is therefore as trustworthy as the Certificate Authority (CA) that issued the certificate.

To protect against compromised or misused certificates, CAs can revoke any certificate by adding it to a Certificate Revocation List (CRL). Certificate status can also be checked online using Online Certificate Status Protocol (OCSP).

RSA X.509 certificates are based on public-key cryptography, in which there are two keys: the private key and the public key. Data encrypted with the private key can be decrypted only with the public key and vice versa. As the names suggest, the private key is never revealed to anyone and the public key can be freely distributed. Encryption with the recipient's public key creates a message that only the intended recipient can read. Encryption with the sender's private key creates a message whose authenticity is proven because it can be decrypted only with the sender's public key.

Server certificates contain a signature string encrypted with the CA's private key. The CA's public key is contained in a CA root certificate. If the signature string can be decrypted with the CA's public key, the certificate is genuine.

## Certificate authorities

A certificate authority can be:

- an organization, such as VeriSign Inc., that provides certificate services
- a software application, such as Microsoft Certificate Services or OpenSSH

For a company web portal or customer-facing SSL VPN, a third-party certificate service has some advantages. The CA certificates are already included in popular web browsers and customers trust the third-party. On the other hand, third-party services have a cost.

For administrators and for employee VPN users, the local CA based on a software application provides the required security at low cost. You can generate and distribute certificates as needed. If an employee leaves the organization, you can simply revoke their certificate.

### Certificates for users

FortiGate unit administrators and SSL VPN users can install certificates in their web browsers to authenticate themselves. If the FortiGate unit uses a CA-issued certificate to authenticate itself to the clients, the browser will also need the appropriate CA certificate.

FortiGate IPsec VPN users can install server and CA certificates according to the instructions for their IPsec VPN client software. The FortiClient Endpoint Security application, for example, can import and store the certificates required by VPN connections.

FortiGate units are also compatible with some Public Key Infrastructure systems. For an example of this type of system, see [RSA ACE \(SecurID\) servers on page 405](#).

### Two-factor authentication

A user can be required to provide both something they know (their username and password combination) and something they have (certificate or a random token code). Certificates are installed on the user's computer.

Two-factor authentication is available for PKI users. For more information, see [Certificate on page 415](#).

Another type of two-factor authentication is to use a randomly generated token (multi-digit number) along with the username and password combination. One method is a FortiToken — a one time passcode (OTP) generator that generates a unique code every 60 seconds. Others use email or SMS text messaging to deliver the random token code to the user or administrator.

When one of these methods is configured, the user enters this code at login after the username and password have been verified. The FortiGate unit verifies the token code after as well as the password and username. For more information, see [Two-factor authentication on page 414](#)

### Authentication binds to MAC address

In FortiOS 5.4.3 and earlier, firewall authentication was source IP based, thus there was no action in response to a MAC address change. This was a security flaw that allowed an unauthenticated user to access restricted resources, especially in a Wi-Fi environment where the IP and MAC binding changed frequently.

FortiOS 5.6.4+ solves this issue by binding the MAC address with the user identity (auth logon) so that the MAC address is matched while matching an auth logon.

## Types of authentication

FortiOS supports two different types of authentication based on your situation and needs.

Security policy authentication is easily applied to all users logging on to a network, or network service. For example if a group of users on your network such as the accounting department who have access to sensitive

data need to access the Internet, it is a good idea to make sure the user is a valid user and not someone trying to send company secrets to the Internet. Security policy authentication can be applied to as many or as few users as needed, and it supports a number of authentication protocols to easily fit with your existing network.

Virtual Private Network (VPN) authentication enables secure communication with hosts located outside the company network, making them part of the company network while the VPN tunnel is operating. Authentication applies to the devices at both ends of the VPN and optionally VPN users can be authenticated as well.

## Security policy authentication

Security policies enable traffic to flow between networks. Optionally, the policy can allow access only to specific originating addresses, device types, users or user groups. Where access is controlled by user or user group, users must authenticate by entering valid username and password credentials.

The user's authentication expires if the connection is idle for too long, five minutes by default but that can be customized.

Security policies are the mechanism for FSSO, NTLM, certificate based, and RADIUS SSO authentication.

## FSSO

Fortinet Single Sign on (FSSO) provides seamless authentication support for Microsoft Windows Active Directory (AD) and Novell eDirectory users in a FortiGate environment.

On a Microsoft Windows or Novell network, users authenticate with the Active Directory or Novell eDirectory at logon. FSSO provides authentication information to the FortiGate unit so that users automatically get access to permitted resources. See [Introduction to agent-based FSSO on page 503](#).

## NTLM

The NT LAN Manager (NTLM) protocol is used when the MS Windows Active Directory (AD) domain controller can not be contacted. NTLM is a browser-based method of authentication.

The FSSO software is installed on each AD server and the FortiGate unit is configured to communicate with each FSSO client. When a user successfully logs into their Windows PC (and is authenticated by the AD Server), the FSSO client communicates the user's name, IP address, and group login information to the FortiGate unit. The FortiGate unit sets up a temporary access policy for the user, so when they attempt access through the firewall they do not need to re-authenticate. This model works well in environments where the FSSO client can be installed on all AD servers.

In system configurations where it is not possible to install FSSO clients on all AD servers, the FortiGate unit must be able to query the AD servers to find out if a user has been properly authenticated. This is achieved using the NTLM messaging features of Active Directory and Internet Explorer.

Even when NTLM authentication is used, the user is not asked again for their username and password. Internet Explorer stores the user's credentials and the FortiGate unit uses NTLM messaging to validate them in the Windows AD environment.

Note that if the authentication reaches the timeout period, the NTLM message exchange restarts. For more information on NTLM, see [NTLM authentication on page 445](#) and [FSSO NTLM authentication support on page 509](#).

## Certificates

Certificates can be used as part of a policy. All users being authenticated against the policy are required to have the proper certificate. See [Certificate-based authentication on page 469](#)

## RADIUS SSO

RADIUS Single Sign-On (RSSO) is a remote authentication method that does not require any local users to be configured, and relies on RADIUS Start records to provide the FortiGate unit with authentication information. That information identifies the user and user group, which is then matched using a security policy. See [SSO using RADIUS accounting records on page 548](#).

## FortiGuard Web Filter override authentication

Optionally, users can be allowed the privilege of overriding FortiGuard Web Filtering to view blocked web sites. Depending on the override settings, the override can apply to the user who requested it, the entire user group to which the user belongs, or all users who share the same web filter profile. As with other FortiGate features, access to FortiGuard overrides is controlled through user groups. Firewall and Directory Services user groups are eligible for the override privilege. For more information about web filtering and overrides, see the UTM chapter of this FortiOS Handbook.

## VPN authentication

Authentication involves authenticating the user. In IPsec VPNs authenticating the user is optional, but authentication of the peer device is required.

This section includes:

- [Authenticating IPsec VPN peers \(devices\)](#)
- [Authenticating IPsec VPN users](#)
- [Authenticating SSL VPN users](#)
- [Authenticating PPTP and L2TP VPN users](#)

### Authenticating IPsec VPN peers (devices)

A VPN tunnel has one end on a local trusted network, and the other end is at a remote location. The remote peer (device) must be authenticated to be able to trust the VPN tunnel. Without that authentication, it is possible for a malicious hacker to masquerade as a valid VPN tunnel device and gain access to the trusted local network.

The three ways to authenticate VPN peers are with a preshared key, RSA X.509 certificate, or a specific peer ID value.

The simplest way for IPsec VPN peers to authenticate each other is through the use of a preshared key, also called a shared secret. The preshared key is a text string used to encrypt the data exchanges that establish the VPN tunnel. The preshared key must be six or more characters. The VPN tunnel cannot be established if the two peers do not use the same key. The disadvantage of preshared key authentication is that it can be difficult to securely distribute and update the preshared keys.

RSA X.509 certificates are a better way for VPN peers to authenticate each other. Each peer offers a certificate signed by a Certificate Authority (CA) which the other peer can validate with the appropriate CA root certificate. For more information about certificates, see [Certificate-based authentication on page 469](#).

You can supplement either preshared key or certificate authentication by requiring the other peer to provide a specific peer ID value. The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

### Authenticating IPsec VPN users

An IPsec VPN can be configured to accept connections from multiple dynamically addressed peers. You would do this to enable employees to connect to the corporate network while traveling or from home. On a FortiGate unit, you create this configuration by setting the **Remote Gateway** to **Dialup User**.

It is possible to have an IPsec VPN in which remote peer devices authenticate using a common preshared key or a certificate, but there is no attempt to identify the user at the remote peer. To add user authentication, you can do one of the following:

- require a unique preshared key for each peer
- require a unique peer ID for each peer
- require a unique peer certificate for each peer
- require additional user authentication (XAuth)

The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

### Authenticating SSL VPN users

SSL VPN users can be

- user accounts with passwords stored on the FortiGate unit
- user accounts authenticated by an external RADIUS, LDAP or TACACS+ server
- PKI users authenticated by certificate

You need to create a user group for your SSL VPN. Simply create a firewall user group, enable SSL VPN access for the group, and select the web portal the users will access.

SSL VPN access requires an SSL VPN security policy that permits access to members of your user group.

### Authenticating PPTP and L2TP VPN users

PPTP and L2TP are older VPN tunneling protocols that do not provide authentication themselves. FortiGate units restrict PPTP and L2TP access to users who belong to one specified user group. Users authenticate themselves to the FortiGate unit by username/password. You can configure PPTP and L2TP VPNs only in the CLI. Before you configure the VPN, create a firewall user group and add to it the users who are permitted to use the VPN. Users are authenticated when they attempt to connect to the VPN. For more information about configuring PPTP or L2TP VPNs, see the FortiGate CLI Reference.

## Single Sign-On authentication for users

“Single Sign-On” means that users logged on to a computer network are authenticated for access to network resources through the FortiGate unit without having to enter their username and password again. FortiGate units directly provide Single Sign On capability for:

- Microsoft Windows networks using either Active Directory or NTLM authentication
- Novell networks, using eDirectory

In combination with a FortiAuthenticator unit, the FortiGate unit can provide Single Sign-On capability that integrates multiple external network authentication systems such as Windows Active Directory, Novell e-Directory, RADIUS and LDAP. The FortiAuthenticator unit gathers user logon information from all of these sources and sends it to the FortiGate unit.

Through the SSO feature, the FortiGate unit knows the username, IP address, and external user groups to which the user belongs. When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

For detailed information about SSO, see

- [Single Sign-On using a FortiAuthenticator unit on page 491](#)
- [Agent-based FSSO on page 503](#)

## User's view of authentication

From the user's point of view, they see a request for authentication when they try to access a protected resource, such as an FTP repository of intellectual property or simply access a website on the Internet. The way the request is presented to the user depends on the method of access to that resource.

VPN authentication usually controls remote access to a private network.

### Web-based user authentication

Security policies usually control browsing access to an external network that provides connection to the Internet. In this case, the FortiGate unit requests authentication through the web browser.

The user types a username and password and then selects **Continue** or **Login**. If the credentials are incorrect, the authentication screen is redisplayed with blank fields so that the user can try again. When the user enters valid credentials, access is granted to the required resource. In some cases, if a user tries to authenticate several times without success, a message appears, such as: "Too many bad login attempts. Please try again in a few minutes." This indicates the user is locked out for a period of time. This prevents automated brute force password hacking attempts. The administrator can customize these settings if required.

After a defined period of user inactivity (the authentication timeout, defined by the FortiGate administrator), the user's access expires. The default is 5 minutes. To access the resource, the user will have to authenticate again.

---

### VPN client-based authentication

A VPN provides remote clients with access to a private network for a variety of services that include web browsing, email, and file sharing. A client program such as FortiClient negotiates the connection to the VPN and manages the user authentication challenge from the FortiGate unit.

FortiClient can store the username and password for a VPN as part of the configuration for the VPN connection and pass them to the FortiGate unit as needed. Or, FortiClient can request the username and password from the user when the FortiGate unit requests them.

Social ID data from FortiClient is recorded so that if an email or phone number is changed on FortiClient, the new values are updated on the FortiGate.

The data is sent in KeepAlive messages in the following format:

```
USR_NAME|<full name for the service account>|USR_
EMAIL|<email for the service
account>|SERVICE|<os|custom|linkedin|google|salesforce>|
```

SSL VPN is a form of VPN that can be used with a standard Web browser. There are two modes of SSL VPN operation (supported in NAT/Route mode only):

- web-only mode, for remote clients equipped with a web-browser only
- tunnel mode, for remote computers that run a variety of client and server applications.

After a defined period of user inactivity on the VPN connection (the idle timeout, defined by the FortiGate administrator), the user's access expires. The default is 30 minutes. To access the resource, the user will have to authenticate again.

## FortiGate administrator's view of authentication

Authentication is based on user groups. The FortiGate administrator configures authentication for security policies and VPN tunnels by specifying the user groups whose members can use the resource. Some planning is required to determine how many different user groups need to be created. Individual user accounts can belong to multiple groups, making allocation of user privileges very flexible.

A member of a user group can be:

- a user whose username and password are stored on the FortiGate unit
- a user whose name is stored on the FortiGate unit and whose password is stored on a remote or external authentication server
- a remote or external authentication server with a database that contains the username and password of each person who is permitted access

The general process of setting up authentication is as follows:

1. If remote or external authentication is needed, configure the required servers.
2. Configure local and peer (PKI) user identities. For each local user, you can choose whether the FortiGate unit or a remote authentication server verifies the password. Peer members can be included in user groups for use in security policies.
3. Create user groups.
4. Add local/peer user members to each user group as appropriate. You can also add an authentication server to a user group. In this case, all users in the server's database can authenticate. You can only configure peer user groups through the CLI.
5. Configure security policies and VPN tunnels that require authenticated access.

For authentication troubleshooting, see the specific chapter for the topic or for general issues see [Troubleshooting on page 574](#).

## General authentication settings

Go to **User & Device > Authentication Settings** to configure authentication timeout, protocol support, and authentication certificates.

When user authentication is enabled within a security policy, the authentication challenge is normally issued for any of the four protocols (depending on the connection protocol):

- HTTP (can also be set to redirect to HTTPS)
- HTTPS
- FTP
- Telnet

The selections made in the **Protocol Support** list of **Authentication Settings** control which protocols support the authentication challenge. Users must connect with a supported protocol first so they can subsequently connect with other protocols. If HTTPS is selected as a method of protocol support, it allows the user to authenticate with a customized Local certificate.

When you enable user authentication within a security policy, the security policy user will be challenged to authenticate. For user ID and password authentication, users must provide their user names and passwords. For certificate authentication (HTTPS or HTTP redirected to HTTPS only), you can install customized certificates on the unit and the users can also have customized certificates installed on their browsers. Otherwise, users will see a warning message and have to accept a default Fortinet certificate.

<b>Authentication Timeout</b>	Enter a length of time in minutes, from 1 to 4320 (72 hours). Authentication timeout controls how long an authenticated firewall connection can be idle before the user must authenticate again. The default value is 5.
<b>Protocol Support</b>	Select the protocols to challenge during firewall user authentication.
<b>Certificate</b>	If using HTTPS protocol support, select the local certificate to use for authentication. Available only if HTTPS protocol support is selected.
<b>Apply</b>	Select to apply the selections for user authentication settings.

## Authentication servers

FortiGate units support the use of external authentication servers. An authentication server can provide password checking for selected FortiGate users or it can be added as a member of a FortiGate user group.

If you are going to use authentication servers, you must configure the servers before you configure FortiGate users or user groups that require them.

Mac OS and iOS devices, including iPhones and iPads, can perform user authentication with FortiOS units using RADIUS servers, but not with LDAP or TACACS+ servers.

---

This section includes the following topics:

- [FortiAuthenticator servers](#)
- [RADIUS servers](#)
- [LDAP servers](#)
- [TACACS+ servers](#)
- [POP3 servers](#)
- [SSO servers](#)
- [RSA ACE \(SecurID\) servers](#)

### FortiAuthenticator servers

FortiAuthenticator is an Authentication, Authorization, and Accounting (AAA) server, that includes a RADIUS server, an LDAP server, and can replace the FSSO Collector Agent on a Windows AD network. Multiple FortiGate units can use a single FortiAuthenticator for FSSO, remote authentication, and FortiToken management.

For more information, see the [FortiAuthenticator Administration Guide](#).

### RADIUS servers

Remote Authentication and Dial-in User Service (RADIUS) is a broadly supported client-server protocol that provides centralized authentication, authorization, and accounting functions. RADIUS clients are built into gateways that allow access to networks such as Virtual Private Network servers, Network Access Servers (NAS), as well as network switches and firewalls that use authentication. FortiGate units fall into the last category.

RADIUS servers use UDP packets to communicate with the RADIUS clients on the network to authenticate users before allowing them access to the network, to authorize access to resources by appropriate users, and to account or bill for those resources that are used. RADIUS servers are currently defined by RFC 2865 (RADIUS) and RFC 2866 (Accounting), and listen on either UDP ports 1812 (authentication) and 1813 (accounting) or ports 1645 (authentication) and 1646 (accounting) requests. RADIUS servers exist for all major operating systems.

You must configure the RADIUS server to accept the FortiGate unit as a client. FortiGate units use the authentication and accounting functions of the RADIUS server.

FortiOS does not accept all characters from auto generated keys from MS Windows 2008. These keys are very long and as a result RADIUS authentication will not work. Maximum key length for MS Windows 2008 is 128 bytes. In older versions of FSAE, it was 40 bytes.

## Microsoft RADIUS servers

Microsoft Windows Server 2000, 2003, and 2008 have RADIUS support built-in. Microsoft specific RADIUS features are defined in RFC 2548. The Microsoft RADIUS implementation can use Active Directory for user credentials.

For details on Microsoft RADIUS server configurations, refer to Microsoft documentation.

## RADIUS user database

The RADIUS user database is commonly an SQL or LDAP database, but can also be any combination of:

- usernames and passwords defined in a configuration file
- user account names and passwords configured on the computer where the RADIUS server is installed.

If users are members of multiple RADIUS groups, then the user group authentication timeout value does not apply. See [Membership in multiple groups on page 426](#).

## RADIUS authentication with a FortiGate unit

To use RADIUS authentication with a FortiGate unit

- configure one or more RADIUS servers on the FortiGate unit
- assign users to a RADIUS server

When a configured user attempts to access the network, the FortiGate unit will forward the authentication request to the RADIUS server which will match the username and password remotely. Once authenticated the RADIUS server passes the authorization granted message to the FortiGate unit which grants the user permission to access the network.

The RADIUS server uses a “shared secret” key along with MD5 hashing to encrypt information passed between RADIUS servers and clients, including the FortiGate unit. Typically only user credentials are encrypted. Additional security can be configured through IPsec tunnels by placing the RADIUS server behind another VPN gateway.

## RADIUS attribute value pairs

RADIUS packets include a set of attribute value pairs (AVP) to identify information about the user, their location and other information. The FortiGate unit sends the following RADIUS attributes.

### FortiOS supported RADIUS attributes

RADIUS Attribute	Name	Description	AVP type
1	Acct-Session-ID	Unique number assigned to each start and stop record to make it easy to match them, and to eliminate duplicate records.	44

RADIUS Attribute	Name	Description	AVP type
2	Username	Name of the user being authenticated	1
3	NAS-Identifier	Identifier or IP address of the Network Access Server (NAS) that is requesting authentication. In this case, the NAS is the FortiGate unit.	32
4	Framed-IP-Address	Address to be configured for the user.	8
5	Fortinet-VSA	See <a href="#">Vendor-specific attributes on page 387</a>	26
6	Acct-Input-Octets	Number of octets received from the port over the course of this service being provided.  Used to charge the user for the amount of traffic they used.	42
7	Acct-Output-Octets	Number of octets sent to the port while delivering this service.  Used to charge the user for the amount of traffic they used.	43
8	NAS-IP-Address	IP address of the Network Access Server (NAS) that is requesting authentication. In this case, the NAS is the FortiGate unit.	4
9	Called-Station-Id	Used to send the telephone number the user called as part of the Access-Request packet.	30
10	Framed-IP-Address	IP address to be configured for the user, by sending the IP address of a user to the RADIUS server in the Access-Request packet.	8
11	Event-Timestamp	Records the time that the event occurred on the NAS. The timestamp is measured in seconds since January 1, 1970 00:00 UTC.  Before the Event-Timestamp attribute can be sent in a packet, make sure that the correct time is set on the FortiGate.	55
12	Class	Used in accounting packets and requests for firewall, WiFi, and proxy authentication. The attribute is returned in Access-Accept message and is added to all accounting packets.	25

The following table describes the supported authentication events and the RADIUS attributes that are sent in the RADIUS accounting message.

**RADIUS attributes sent in RADIUS accounting message**

Authentication Method	RADIUS Attributes						
	1	2	3	4	5	6	7
Web	X	X	X		X		
XAuth of IPsec (without DHCP)	X	X	X		X		
XAuth of IPsec (with DHCP)	X	X	X	X	X		
PPTP/L2TP (in PPP)	X	X	X	X	X	X	X
SSL-VPN	X	X	X	X	X		

**External captive portal POST message**

In external RADIUS captive portal, the captive portal web page is a script that gathers the user's logon credentials and sends it back to the FortiGate as a POST message. Session URL parameters are sent from the client in a POST messages, and in the redirect. These parameters are separated by **&** characters (see examples below):

**POST message to redirect server:**

```
http://<redirectserver>/index2.php/?login&post=http://192.168.200.1:1000/fgtauth&magic=02050f889bc21644&usermac=54:26:96:16:a2:45&apmac=00:09:0f:b9:f4:c0&apip=127.0.0.1&userip=192.168.200.2
```

**POST message back to the FortiGate:**

```
http://FGT_IP_addr:1000/fgtauth
```

The magic text data, provided in the initial FortiGate request to the web server, contains the username, password parameters:

```
magic=00050c839182f095&username=<username>&password=<password>
```

**Vendor-specific attributes**

Vendor specific attributes (VSA) are the method RADIUS servers and client companies use to extend the basic functionality of RADIUS. Some major vendors, such as Microsoft, have published their VSAs, however many do not.

In order to support vendor-specific attributes (VSA), the RADIUS server requires a dictionary to define which VSAs to support. This dictionary is typically supplied by the client or server vendor.

The Fortinet RADIUS vendor ID is 12356.

The FortiGate unit RADIUS VSA dictionary is supplied by Fortinet and is available through the Fortinet Knowledge Base (<http://kb.forticare.com>) or through Technical Support. Fortinet's dictionary for FortiOS 4.0 and up is configured this way:

```
##
Fortinet's VSA's
```

```
#
VENDOR fortinet 12356
BEGIN-VENDOR fortinet
ATTRIBUTE Fortinet-Group-Name 1 string
ATTRIBUTE Fortinet-Client-IP-Address 2 ipaddr
ATTRIBUTE Fortinet-Vdom-Name 3 string
ATTRIBUTE Fortinet-Client-IPv6-Address 4 octets
ATTRIBUTE Fortinet-Interface-Name 5 string
ATTRIBUTE Fortinet-Access-Profile 6 string
#
# Integer Translations
#
END-VENDOR Fortinet
```

Note that using the Fortinet-Vdom-Name, users can be tied to a specific VDOM on the FortiGate unit. See the documentation provided with your RADIUS server for configuration details.

## RADIUS CoA support

As of FortiOS 5.4, RADIUS Change of Authorization (CoA) settings can be configured via the CLI. CoA is a common feature in user authentication that provides the ability to change authentication attributes for sessions even after they have authenticated.

User, user group, and captive portal authentication supports RADIUS CoA, when the back end authentication server is RADIUS. The main use case of this feature is with external captive portal, where it can be used to disconnect hotspot users when their time, credit, or bandwidth has been used up.

The commands below control CoA settings.

1. Set the name of the FortiAP connected to the FortiGate as a location identifier.

```
config system global
set alias <name>
```

2. Set URL of external authentication logout server.

```
config vdom
edit root
config wireless-controller vap
edit <example>
set security captive-portal
set external-logout
```

3. Set URL of external authentication logout server

```
config vdom
edit root
config system interface
edit <example>
set security captive-portal
set security-external-logout
```

4. Set class name(s) included in an Access-Accept message.

```
config vdom
edit root
config user radius
edit accounting
set class <"A1=aaa" "B2=bbb" "C3=ccc">
```

## Role Based Access Control

In Role Based Access Control (RBAC), network administrators and users have varying levels of access to network resources based on their role, and that role's requirement for access specific resources. For example, a junior accountant does not require access to the sales presentations, or network user account information.

There are three main parts to RBAC: role assignment, role authorization, and transaction authorization. Role assignment is accomplished when someone in an organization is assigned a specific role by a manager or HR. Role authorization is accomplished when a network administrator creates that user's RADIUS account and assigns them to the required groups for that role. Transaction authorization occurs when that user logs on and authenticates before performing a task.

RBAC is enforced when FortiOS network users are remotely authenticated via a RADIUS server. For users to authenticate, a security policy must be matched. That policy only matches a specific group of users. If VDOMs are enabled, the matched group will be limited to a specific VDOM. Using this method network administrators can separate users into groups that match resources, protocols, or VDOMs. It is even possible to limit users to specific FortiGate units if the RADIUS servers serve multiple FortiOS units.

For more information on security policies, see [Authentication in security policies on page 440](#).

## RADIUS password encoding

Certain RADIUS servers use ISO-8859-1 password encoding instead of others such as UTF-8. In these instances, the server will fail to authenticate the user, if the user's password is using UTF-8.

### CLI syntax

```
config user radius
  edit <example>
    set password-encoding <auto | ISO-8859-1>
  end
```

This option will be skipped if the `auth-type` is neither `auto` nor `pap`.

## RADIUS accounting start message options

Administrators can now choose between sending accounting start messages to all configured accounting servers, or just the one server that was previously connected.

### Syntax

```
config user radius
  edit <name>
    set acct-interim-interval <seconds>
    set acct-all-servers {enable | disable}
  next
end
```

## Configuring the FortiGate unit to use a RADIUS server

The information you need to configure the FortiGate unit to use a RADIUS server includes

- the RADIUS server's domain name or IP address
- the RADIUS server's shared secret key.

You can optionally specify the NAS IP or Called Station ID. When configuring the FortiGate to use a RADIUS server, the FortiGate is a Network Access Server (NAS). If the FortiGate interface has multiple IP addresses, or you want the RADIUS requests to come from a different address you can specify it here. Called Station ID applies to carrier networks. However, if the NAS IP is not included in the RADIUS configuration, the IP of the FortiGate unit interface that communicates with the RADIUS server is used instead.

A maximum of 10 remote RADIUS servers can be configured on the FortiGate unit. One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see [Local and remote users on page 411](#).

On the FortiGate unit, the default port for RADIUS traffic is 1812. Some RADIUS servers use port 1645. If this is the case with your server, you can either:

- Re-configure the RADIUS server to use port 1812. See your RADIUS server documentation for more information on this procedure.

or

- Change the FortiGate unit default RADIUS port to 1645 using the CLI:

```
config system global
    set radius-port 1645
end
```

One wildcard admin account can be added to the FortiGate unit when using RADIUS authentication. This uses the wildcard character to allow multiple admin accounts on RADIUS to use a single account on the FortiGate unit. See [Example — wildcard admin accounts - CLI on page 397](#).

### To configure the FortiGate unit for RADIUS authentication - web-based manager:

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter the following information and select **OK**.

<b>Name</b>	A name to identify the RADIUS server on the FortiGate unit.
<b>Primary Server Name/IP</b>	Enter the domain name (such as fgt.exmaple.com) or the IP address of the RADIUS server.
<b>Primary Server Secret</b>	Enter the server secret key, such as radiusSecret. This can be a maximum of 16 characters long.  This must match the secret on the RADIUS primary server.
<b>Secondary Server Name/IP</b>	Optionally enter the domain name (such as fgt.exmaple.com) or the IP address of the secondary RADIUS server.
<b>Secondary Server Secret</b>	Optionally, enter the secondary server secret key, such as radiusSecret2. This can be a maximum of 16 characters long.  This must match the secret on the RADIUS secondary server.
<b>Authentication Scheme</b>	If you know the RADIUS server uses a specific authentication protocol, select it from the list. Otherwise select <b>Use Default Authentication Scheme</b> . The Default option will usually work.

**NAS IP/ Called Station ID**

Enter the IP address to be used as an attribute in RADIUS access requests.

**NAS-IP-Address** is RADIUS setting or IP address of FortiGate interface used to talk to RADIUS server, if not configured.

**Called Station ID** is same value as NAS-IP Address but in text format.

**Include in every User Group**

When enabled this RADIUS server will automatically be included in all user groups. This is useful if all users will be authenticating with the remote RADIUS server.

For MAC OS and iOS devices to authenticate, you must use MS-CHAP-v2 authentication. In the CLI, the command is `set auth-type ms_chap_v2`.

### 3. Select **OK**.

#### To configure the FortiGate unit for RADIUS authentication - CLI example:

```
config user radius
edit ourRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret radiusSecret
end
```

For more information about RADIUS server options, refer to the FortiGate CLI Reference.

### Troubleshooting RADIUS

To test the connection to the RADIUS server use the following command:

```
diagnose test authserver radius-direct <server_name or IP> <port number> <secret>
```

For the port number, enter `-1` to use the default port. Otherwise enter the port number to check.

Test results show RADIUS server reachability, NAS client rejection, and invalid User/Password. Test also shows RADIUS Attributes returned from the RADIUS server.

## LDAP servers

Lightweight Directory Access Protocol (LDAP) is an Internet protocol used to maintain authentication data that may include departments, people, groups of people, passwords, email addresses, and printers. LDAP consists of a data-representation scheme, a set of defined operations, and a request/response network.

The scale of LDAP servers range from big public servers such as BigFoot and Infospace, to large organizational servers at universities and corporations, to small LDAP servers for workgroups that may be using OpenLDAP. This document focuses on the institutional and workgroup applications of LDAP.

This section includes:

- [Components and topology](#)
- [LDAP directory organization](#)
- [Configuring the FortiGate unit to use an LDAP server](#)
- [Example — wildcard admin accounts - CLI](#)
- [Example of LDAP to allow Dial-in through member-attribute - CLI](#)
- [Troubleshooting LDAP](#)

## Components and topology

LDAP organization starts with directories. A directory is a set of objects with similar attributes organized in a logical and hierarchical way. Generally, an LDAP directory tree reflects geographic and organizational boundaries, with the Domain name system (DNS) names to structure the top level of the hierarchy. The common name identifier for most LDAP servers is `cn`, however some servers use other common name identifiers such as `uid`.

When LDAP is configured and a user is required to authenticate the general steps are:

1. The FortiGate unit contacts the LDAP server for authentication.
2. To authenticate with the FortiGate unit, the user enters a username and password.
3. The FortiGate unit sends this username and password to the LDAP server.
4. If the LDAP server can authenticate the user, the user is successfully authenticated with the FortiGate unit.
5. If the LDAP server cannot authenticate the user, the connection is refused by the FortiGate unit.

## Binding

Binding is the step where the LDAP server authenticates the user. If the user is successfully authenticated, binding allows the user access to the LDAP server based on that user's permissions.

The FortiGate unit can be configured to use one of three types of binding:

- anonymous - bind using anonymous user search
- regular - bind using username/password and then search
- simple - bind using a simple password authentication without a search

You can use simple authentication if the user records all fall under one domain name (`dn`). If the users are under more than one `dn`, use the anonymous or regular type, which can search the entire LDAP database for the required username.

If your LDAP server requires authentication to perform searches, use the regular type and provide values for username and password.

## Supported versions

The FortiGate unit supports LDAP protocol functionality defined in RFC 2251: Lightweight Directory Access Protocol v3, for looking up and validating user names and passwords. FortiGate LDAP supports all LDAP servers compliant with LDAP v3, including FortiAuthenticator. In addition, FortiGate LDAP supports LDAP over SSL/TLS, which can be configured only in the CLI.

FortiGate LDAP does not support proprietary functionality, such as notification of password expiration, which is available from some LDAP servers. FortiGate LDAP does not supply information to the user about why authentication failed.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

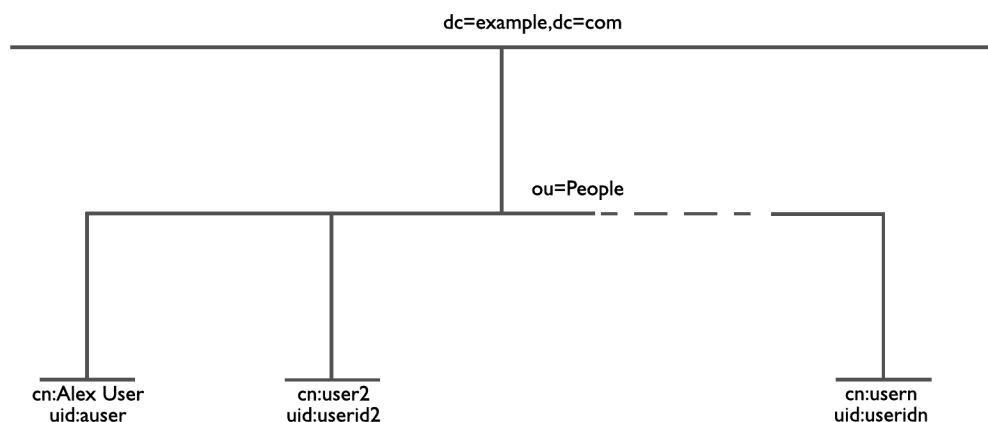

## LDAP directory organization

To configure your FortiGate unit to work with an LDAP server, you need to understand the organization of the information on the server.

The top of the hierarchy is the organization itself. Usually this is defined as Domain Component (DC), a DNS domain. If the name contains a dot, such as `example.com`, it is written as two parts separated by a comma: `dc=example,dc=com`.

In this example, Common Name (CN) identifiers reside at the Organization Unit (OU) level, just below DC. The Distinguished Name (DN) is `ou=People,dc=example,dc=com`.

## LDAP object hierarchy

In addition to the DN, the FortiGate unit needs an identifier for the individual person. Although the FortiGate unit GUI calls this the Common Name (CN), the identifier you use is not necessarily CN. On some servers, CN is the full name of a person. It might be more convenient to use the same identifier used on the local computer network. In this example, User ID (UID) is used.

## Locating your identifier in the hierarchy

You need to determine the levels of the hierarchy from the top to the level that contain the identifier you want to use. This defines the DN that the FortiGate unit uses to search the LDAP database. Frequently used distinguished name elements include:

- uid (user identification)
- pw (password)
- cn (common name)
- ou (organizational unit)
- o (organization)
- c (country)

One way to test this is with a text-based LDAP client program. For example, OpenLDAP includes a client, `ldapsearch`, that you can use for this purpose.

Enter the following at the command line:

```
ldapsearch -x '(objectclass=*)'
```

The output is lengthy, but the information you need is in the first few lines:

```
version: 2
#
# filter: (objectclass=*)
# requesting: ALL

dn: dc=example,dc=com
dc: example
objectClass: top
objectClass: domain

dn: ou=People,dc=example,dc=com
ou: People
objectClass: top
objectClass: organizationalUnit
...
dn: uid=tbrown,ou=People,dc=example,dc=com
uid: tbrown
cn: Tom Brown
```

In the output above, you can see `tbrown` (uid) and `Tom Brown` (cn). Also note the dn is `ou=People, dc=example, dc=com`.

## Configuring the FortiGate unit to use an LDAP server

After you determine the common name and distinguished name identifiers and the domain name or IP address of the LDAP server, you can configure the server on the FortiGate unit. The maximum number of remote LDAP servers that can be configured is 10.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see [Local and remote users on page 411](#).

### To configure the FortiGate unit for LDAP authentication - web-based manager:

1. Go to **User & Device > LDAP Servers** and select **Create New**.
2. Enter a **Name** for the LDAP server.
3. In **Server Name/IP** enter the server's FQDN or IP address.
4. If necessary, change the **Server Port** number. The default is port 389.
5. Enter the **Common Name Identifier** (20 characters maximum).  
`cn` is the default, and is used by most LDAP servers.
6. In the **Distinguished Name** field, enter the base distinguished name for the server using the correct X.500 or LDAP format.  
The FortiGate unit passes this distinguished name unchanged to the server. The maximum number of characters is 512.  
If you don't know the distinguished name, leave the field blank and select the Query icon to the right of the field. See [Using the Query icon on page 396](#).

7. In the **Distinguished Name** field, enter the base distinguished name for the server using the correct X.500 or LDAP format.  
The FortiGate unit passes this distinguished name unchanged to the server. The maximum number of characters is 512.  
If you don't know the distinguished name, leave the field blank and select the Query icon to the right of the field.  
See [Using the Query icon on page 396](#).
8. In **Bind Type**, select **Regular**.
9. In **User DN**, enter the LDAP administrator's distinguished name.
10. In **Password**, enter the LDAP administrator's password.
11. Select **OK**.

To verify your Distinguished Name field is correct, you can select the **Test** button. If your DN field entry is valid, you will see the part of the LDAP database it defines. If your DN field entry is not valid, it will display an error message and return no information.

---

For detailed information about configuration options for LDAP servers, see the Online Help on your FortiGate unit or the FortiGate CLI Reference.

#### To configure the FortiGate unit for LDAP authentication - CLI example:

```
config user ldap
  edit ourLDAPsrv
    set server 10.11.101.160
    set cnid cn
    set dn cn=users,dc=office,dc=example,dc=com
    set type regular
    set username cn=administrator,cn=users,dc=office,dc=example,dc=com
    set password w5AiGVMLkgyPQ
    set password-expiry-warning enable
    set password-renewal enable
  end
```

#### password-expiry-warning and password-renewal

In SSLVPN, when an LDAP user is connecting to the LDAP server it is possible for them to receive any pending password expiry or renewal warnings. When the password renewal or expiry warning exists, SSLVPN users will see a prompt allowing them to change their password.

`password-expiry-warning` allows FortiOS to detect from the OpenLDAP server when a password is expiring or has expired using server controls or error codes. Please note that this is currently not supported for Windows AD LDAP.

`password-renewal` allows FortiOS to perform the online LDAP password renewal operations the LDAP server expects.

On an OpenLDAP server, when a user attempts to logon with an expired password they are allowed to logon but only to change their password.

When changing passwords on a Windows AD system, the connection must be SSL-protected.

## UPN processing method and filter name

The following CLI commands available under `config user ldap` allow you to keep or strip the domain string of UPN in the token as well as the search name for this kind of UPN.

### CLI syntax:

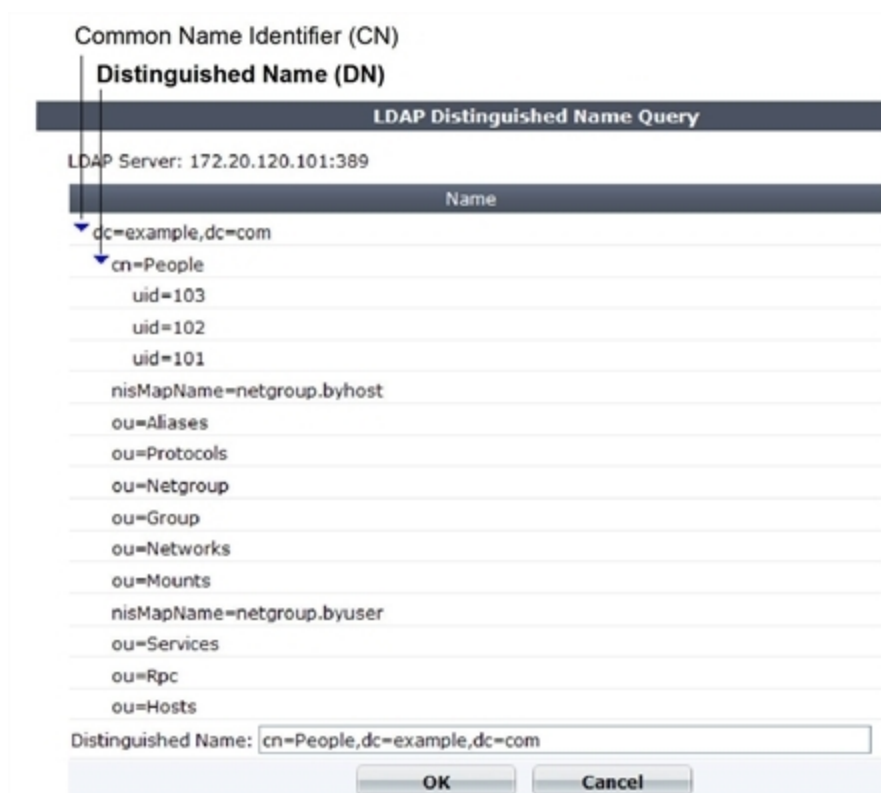

```
config user ldap
    set account-key-processing
    set account-key-name
end
```

### Using the Query icon

The LDAP Distinguished Name Query list displays the LDAP directory tree for the LDAP server connected to the FortiGate unit. This helps you to determine the appropriate entry for the DN field. To see the distinguished name associated with the Common Name identifier, select the Expand icon next to the CN identifier. Select the DN from the list. The DN you select is displayed in the Distinguished Name field. Select OK and the Distinguished Name you selected will be saved in the Distinguished Name field of the LDAP Server configuration.

To see the users within the LDAP Server user group for the selected Distinguished Name, expand the Distinguished Name in the LDAP Distinguished Name Query tree.

### LDAP server Distinguished Name Query tree

## Non-blocking LDAP authentication

To support non-blocking LDAP authentication, `fnbamd` will create its own event-driven connection with LDAP servers over LDAP/LDAPS/STARTTLS, make it non-blocking, do CRL checking if necessary, and compose all LDAP requests using `liblber` (including bind, unbind, search, password renewal, password query, send request and receive response, and parse response). The whole process is done in one connection.

This doesn't change any openLDAP implementation but moves some data structure definitions and API definitions from some internal header files to public header files.

## Example — wildcard admin accounts - CLI

A wildcard admin account is an administrator account with the wildcard option enabled. This option allows multiple different remote administration accounts to match one local administration account, avoiding the need to set up individual admin accounts on the FortiGate unit. Instead multiple LDAP admin accounts will all be able to use one FortiGate admin account.

The initial benefit of wildcard admin accounts is fast configuration of the FortiGate unit's administration account to work with your LDAP network. The many to one ratio saves on effort, and potential errors.

The ongoing benefit is that as long as the users on the LDAP system belong to that group, and the test admin user settings don't change on the FortiGate unit, no other work is required. This point is important as it can help avoid system updates or changes that would otherwise require changes to the LDAP administrator account configuration. Even if a user is added to or removed from the LDAP group, no changes are required on the FortiGate unit.

Two potential issues with wildcard admin accounts are that multiple users may be logged on to the same account at the same time. This becomes an issue if they are changing the same information at the same time. The other potential issue is that security is reduced because multiple people have login access for the same account. If each user was assigned their own account, a hijacking of one account would not affect the other users.

Note that wildcard admin configuration also applies to RADIUS. When configuring for RADIUS, configure the RADIUS server, and RADIUS user group instead of LDAP. When using web-based management, wildcard admin is the only type of remote administrator account that does not require you to enter a password on account creation. That password is normally used when the remote authentication server is unavailable during authentication.

In this example, default values are used where possible. If a specific value is not mentioned, it is set to its default value.

## Configuring the LDAP server

The important parts of this configuration are the username and group lines. The username is the domain administrator account. The group binding allows only the group with the name `GRP` to access.

The `dn` used here is as an example only. On your network use your own domain name.

---

### To configure LDAP server - CLI:

```
config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
```

```

        set cnid "sAMAccountName"
        set dn "DC=example,DC=com,DC=au"
        set type regular
        set username "CN=Administrator,CN=Users,DC=example,DC=COM"
        set password *
        set group-member-check group-object
        set group-object-filter (&
            (objectcategory=group)member="CN=GRP,OU=training,DC=example,DC=COM")
    next
end

```

### To configure the user group and add the LDAP server - CLI:

```

config user group
    edit "ldap_grp"
        set member "ldap"
        config match
            edit 1
                set server-name "ldap_server"
                set group-name "CN=GRP,OU=training,DC=example,DC=COM"
            next
        end
    next
end

```

### Configuring the admin account

The wildcard part of this example is only available in the CLI for admin configuration. When enabled, this allows all LDAP group members to login to the FortiGate unit without the need to create a separate admin account for each user. In effect the members of that group will each be able to login as “test”.

### To configure the admin account - CLI:

```

config system admin
    edit "test"
        set remote-auth enable
        set accprofile "super_admin"
        set wildcard enable
        set remote-group "ldap_grp"
    next
end

```

For troubleshooting, test that the admin account is operational, and see [Troubleshooting LDAP on page 399](#).

### Example of LDAP to allow Dial-in through member-attribute - CLI

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to setup a VPN connection simply based on an attribute that is set to TRUE, instead of based on being part of a specific group.

In AD, the “Allow Dial-In” property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to “TRUE”.

This same procedure can be used for other member attributes, as your system requires.

## Configuring LDAP member-attribute settings

To accomplish this with a FortiGate unit, the member attribute must be set. Setting member attributes can only be accomplished through the CLI using the `member-attr` keyword - the option is not available through the web-based manager.

Before configuring the FortiGate unit, the AD server must be configured and have the `msNPAllowDialin` attribute set to "TRUE" for the users in question. If not, those users will not be able to properly authenticate.

The dn used here is as an example only. On your network use your own domain name.

### To configure user LDAP member-attribute settings - CLI:

```
config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
    set cnid "sAMAccountName"
    set dn "DC=fortinet,DC=com,DC=au"
    set type regular
    set username "fortigate@example.com"
    set password *****
    set member-attr "msNPAllowDialin"
  next
end
```

## Configuring LDAP group settings

A user group that will use LDAP must be configured. This example adds the member `ldap` to the group which is the LDAP server name that was configured earlier.

### To configure LDAP group settings - CLI:

```
config user group
  edit "ldap_grp"
    set member "ldap"
    config match
    edit 1
      set server-name "ldap"
      set group-name "TRUE"
    next
  end
end
```

Once these settings are in place, users can authenticate.

## Troubleshooting LDAP

The examples in this section use the values from the previous example.

### LDAP user test

A quick way to see if the LDAP configuration is correct is to run a `diagnose` CLI command with LDAP user information. The following command tests with a user called `netAdmin` and a password of `fortinet`. If the configuration is correct the test will be successful.

```
FGT# diag test authserver ldap ldap_server netAdmin fortinet
```

'ldap\_server' is not a valid ldap server name — an LDAP server by that name has not been configured on the FortiGate unit, check your spelling.

authenticate 'netAdmin' against 'ldap\_server' failed! — the user netAdmin does not exist on ldap\_server, check your spelling of both the user and sever and ensure the user has been configured on the FortiGate unit.

### LDAP authentication debugging

For a more in-depth test, you can use a `diag debug` command. The sample output from a shows more information about the authentication process that may prove useful if there are any problems.

Ensure the “Allow Dial-in” attribute is still set to “TRUE” and run the following CLI command. `fnbamd` is the Fortinet non-blocking authentication daemon.

```
FGT# diag debug enable
FGT# diag debug reset
FGT# diag debug application fnbamd -1
FGT# diag debug enable
```

The output will look similar to:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='TRUE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Passed group matching
```

If the “Allow Dial-in” attribute is not set but it is expected, the last line of the above output will instead be:

```
fnbamd_auth_poll_ldap-Failed group matching
```

## TACACS+ servers

When users connect to their corporate network remotely, they do so through a remote access server. As remote access technology has evolved, the need for security when accessing networks has become increasingly important. This need can be filled using a Terminal Access Controller Access-Control System (TACACS+) server.

TACACS+ is a remote authentication protocol that provides access control for routers, network access servers, and other networked computing devices via one or more centralized servers. TACACS+ allows a client to accept a username and password and send a query to a TACACS+ authentication server. The server host determines whether to accept or deny the request and sends a response back that allows or denies the user access to the network.

TACACS+ offers fully encrypted packet bodies, and supports both IP and AppleTalk protocols. TACACS+ uses TCP port 49, which is seen as more reliable than RADIUS's UDP protocol.

There are several different authentication protocols that TACACS+ can use during the authentication process:

## Authentication protocols

Protocol	Definition
<b>ASCII</b>	Machine-independent technique that uses representations of English characters. Requires user to type a username and password that are sent in clear text (unencrypted) and matched with an entry in the user database stored in ASCII format.
<b>PAP</b>	Password Authentication Protocol (PAP) Used to authenticate PPP connections. Transmits passwords and other user information in clear text.
<b>CHAP</b>	Challenge-Handshake Authentication Protocol (CHAP) Provides the same functionality as PAP, but is more secure as it does not send the password and other user information over the network to the security server.
<b>MS-CHAP</b>	MicroSoft Challenge-Handshake Authentication Protocol v1 (MSCHAP) Microsoft-specific version of CHAP.
<b>default</b>	The default protocol configuration, Auto, uses PAP, MS-CHAP, and CHAP, in that order.

## TACACS+ attribute value pairs

FortiGate sends the following proprietary TACACS+ attributes to the TACACS+ server during authorization requests:

- **service=<name>**: The user must be authorized to access the service specified.
- **memberof**: The group that the user belongs to.
- **admin\_prof**: The administrator profile (admin access only).

Note that only the **memberof** and **admin\_prof** attributes are also parsed in authentication replies.

## Configuring a TACACS+ server on the FortiGate unit

A maximum of 10 remote TACACS+ servers can be configured for authentication.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see [Local and remote users on page 411](#).

The TACACS+ page in the web-based manager (**User & Device > TACACS+ Servers**) is not available until a TACACS+ server has been configured in the CLI. For more information see the CLI Reference.

### To configure the FortiGate unit for TACACS+ authentication - web-based manager:

1. Go to **User & Device > TACACS+ Servers** and select **Create New**.
2. Enter the following information, and select **OK**.

<b>Name</b>	Enter the name of the TACACS+ server.
-------------	---------------------------------------

<b>Server Name/IP</b>	Enter the server domain name or IP address of the TACACS+ server.
<b>Server Key</b>	Enter the key to access the TACACS+ server.
<b>Authentication Type</b>	Select the authentication type to use for the TACACS+ server. <b>Auto</b> tries PAP, MSCHAP, and CHAP (in that order).

### To configure the FortiGate unit for TACACS+ authentication - CLI:

```

config user tacacs+
    edit "TACACS-SERVER"
        set server [IP_ADDRESS]
        set key [PASSWORD]
        set authen-type ascii
    next
end
config user group
    edit "TACACS-GROUP"
        set group-type firewall
        set member "TACACS-SERVER"
    next
end
config system admin
    edit TACACS-USER
        set remote-auth enable
        set accprofile "super_admin"
        set vdom "root"
        set wildcard enable
        set remote-group "TACACS-GROUP"
    next
end

```

### IPv6 TACACS+ server IP address

IPv6 address support is available for TACACS+ servers.

### Syntax

```

config user tacacs+
    edit <name>
        set server <ipv6 address>
        set source-ipv6 <ipv6 address>
    next
end

```

## POP3 servers

FortiOS can authenticate users who have accounts on POP3 or POP3s email servers. POP3 authentication can be configured only in the CLI.

### To configure the FortiGate unit for POP3 authentication:

```

config user pop3
    edit pop3_server1
        set server pop3.fortinet.com
    next
end

```

```
set secure starttls
set port 110
end
```

### To configure a POP3 user group:

```
config user group
edit pop3_grp
set member pop3_server1
end
```

A user group can list up to six POP3 servers as members.

## SSO servers

Novell and Microsoft Windows networks provide user authentication based on directory services: eDirectory for Novell, Active Directory for Windows. Users can log on at any computer in the domain and have access to resources as defined in their user account. The Fortinet Single Sign On (FSSO) agent enables FortiGate units to authenticate these network users for security policy or VPN access without asking them again for their username and password.

When a user logs in to the Windows or Novell domain, the FSSO agent sends to the FortiGate unit the user's IP address and the names of the user groups to which the user belongs. The FortiGate unit uses this information to maintain a copy of the domain controller user group database. Because the domain controller authenticates users, the FortiGate unit does not perform authentication. It recognizes group members by their IP address.

In the FortiOS FSSO configuration, you specify the server where the FSSO Collector agent is installed. The Collector agent retrieves the names of the Novell or Active Directory user groups from the domain controllers on the domains, and then the FortiGate unit gets them from the Collector agent. You cannot use these groups directly. You must define FSSO type user groups on your FortiGate unit and then add the Novell or Active Directory user groups to them. The FSSO user groups that you created are used in security policies and VPN configurations to provide access to different services and resources.

FortiAuthenticator servers can replace the Collector agent when FSSO is using polling mode. The benefits of this is that FortiAuthenticator is a stand-alone server that has the necessary FSSO software pre-installed. For more information, see the FortiAuthenticator Administration Guide.

### Single Sign-on Agent configuration settings

The following are SSO configuration settings in **User & Device > Single Sign-On**.

#### SSO Server List

Lists all the collector agents' lists that you have configured. On this page, you can create, edit or delete FSSO agents. There are different types of FSSO agents, each with its own settings.

You can create a redundant configuration on your unit if you install a collector agent on two or more domain controllers. If the current (or first) collector agent fails, the Fortinet unit switches to the next one in its list of up to five collector agents.

---

<b>Create New</b>	Creates a new agent. When you select <b>Create New</b> , you are automatically redirected to the New page.
<b>Edit</b>	<p>Modifies the settings for the selected SSO server.</p> <p>To remove multiple entries from the list, for each servers you want removed, select the check box and then select <b>Delete</b>.</p> <p>To remove all agents from the list, on the FSSO Agent page, select the check box at the top of the check box column and then select <b>Delete</b>.</p>
<b>Delete</b>	Removes an agent from the list on the page.

#### Settings when Type is Poll Active Directory Server

<b>Server IP/Name</b>	The IP address of the domain controller (DC).
<b>User</b>	The user ID used to access the domain controller.
<b>Password</b>	Enter the password for the account used to access the DC.
<b>LDAP Server</b>	Select the check box and select an LDAP server to access the Directory Service.
<b>Enable Polling</b>	Enable to allow the FortiGate unit to poll this DC.
<b>Users/Groups</b>	A list of user and user group names retrieved from the DC.

#### Settings when Type is Fortinet Single Sign On Agent

<b>Name</b>	Enter a name for the SSO server.
<b>Primary Agent IP/Name</b>	Enter the IP address or name of the Directory Service server where this SSO agent is installed. The maximum number of characters is 63.
<b>Secondary Agent IP/Name</b>	
<b>Password</b>	Enter the password for the collector agent. This is required only if you configured your Fortinet Single Sign On Agent collector agent to require authenticated access.
<b>LDAP Server</b>	Select the check box and select an LDAP server to access the Directory Service.
<b>More FSSO agents</b>	Select to add up to three additional SSO agents.
<b>Users/Groups</b>	A list of user and user group names retrieved from the server.

**Settings when Type is RADIUS Single Sign On Agent**

<b>Use RADIUS Shared Secret</b>	Enable
<b>Shared Secret</b>	Enter the RADIUS server shared secret.
<b>Send RADIUS Responses</b>	Enable.

## RSA ACE (SecurID) servers

SecurID is a two-factor system that uses one-time password (OTP) authentication. It is produced by the company RSA. This system includes portable tokens carried by users, an RSA ACE/Server, and an Agent Host. In our configuration, the FortiGate unit is the Agent Host.

### Components

When using SecurID, users carry a small device or “token” that generates and displays a pseudo-random password. According to RSA, each SecurID authenticator token has a unique 64-bit symmetric key that is combined with a powerful algorithm to generate a new code every 60 seconds. The token is time-synchronized with the SecurID RSA ACE/Server.

The RSA ACE/Server is the management component of the SecurID system. It stores and validates the information about the SecurID tokens allowed on your network. Alternately the server could be an RSA SecurID 130 Appliance.

The Agent Host is the server on your network, in this case it is the FortiGate unit, that intercepts user logon attempts. The Agent Host gathers the user ID and password entered from their SecurID token, and sends that information to the RSA ACE/Server to be validated. If valid, a reply comes back indicating it is a valid logon and the FortiGate unit allows the user access to the network resources specified in the associated security policy.

### Configuring the SecurID system

To use SecurID with a FortiGate unit, you need:

- to configure the RSA server and the RADIUS server to work with each other (see RSA server documentation)
- [to configure the RSA SecurID 130 Appliance](#)
- or
- [to configure the FortiGate unit as an Agent Host on the RSA ACE/Server](#)
- [to configure the FortiGate unit to use the RADIUS server](#)
- [to create a SecurID user group](#)
- [to configure a security policy with SecurID authentication](#)

The following instructions are based on RSA ACE/Server version 5.1, or RSA SecurID 130 Appliance, and assume that you have successfully completed all the external RSA and RADIUS server configuration steps listed above.

For this example, the RSA server is on the internal network, with an IP address of 192.128.100.100. The FortiGate unit internal interface address is 192.168.100.3, RADIUS shared secret is fortinet123, RADIUS server is at IP address 192.168.100.102.

### To configure the RSA SecurID 130 Appliance

1. Go to the IMS Console for SecurID and logon.
2. Go to **RADIUS > RADIUS Clients**, and select **Add New**.
3. Enter the following information to configure your FortiGate as a SecurID Client, and select Save.

RADIUS Client Basics	
<b>Client Name</b>	FortiGate
<b>Associated RSA Agent</b>	FortiGate
RADIUS Client Settings	
<b>IP Address</b>	192.168.100.3
	The IP address of the FortiGate unit internal interface.
<b>Make / Model</b>	Select Standard Radius
<b>Shared Secret</b>	fortinet123
	The RADIUS shared secret.
<b>Accounting</b>	Leave unselected
<b>Client Status</b>	Leave unselected

### To configure the FortiGate unit as an Agent Host on the RSA ACE/Server

1. On the RSA ACE/Server computer, go to **Start > Programs > RSA ACE/Server**, and then **Database Administration - Host Mode**.
2. On the **Agent Host** menu, select **Add Agent Host**.
3. Enter and save the following information.

<b>Name</b>	FortiGate
<b>Network Address</b>	192.168.100.3
	The IP address of the FortiGate unit.
<b>Secondary Nodes</b>	Optionally enter other IP addresses that resolve to the FortiGate unit.

If needed, refer to the RSA ACE/Server documentation for more information.

### To configure the FortiGate unit to use the RADIUS server

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter the following information, and select **OK**.

<b>Name</b>	RSA
<b>Primary Server IP/Name</b>	192.168.100.102 Optionally select Test to ensure the IP address is correct and the FortiGate can contact the RADIUS server.
<b>Primary Server Secret</b>	fortinet123
<b>Authentication Scheme</b>	Select <b>Use Default Authentication Scheme</b> .

### To create a SecurID user group

1. Go to **User & Device > User Groups**, and select **Create New**.
2. Enter the following information.

<b>Name</b>	RSA_group
<b>Type</b>	Firewall

3. In **Remote Groups**, select **Add**, then select the RSA server.
4. Select **OK**.

### To create a SecurID user:

1. Go to **User & Device > User Definition**, and select **Create New**.
2. Use the wizard to enter the following information, and then select **Create**.

<b>User Type</b>	Remote RADIUS User
<b>User Name</b>	wloman
<b>RADIUS Server</b>	RSA
<b>Contact Info</b>	(optional) Enter Email or SMS information
<b>User Group</b>	RSA_group

To test this configuration, on your FortiGate unit use the CLI command:

```
diagnose test authserver radius RSA auto wloman 111111111
```

The series of 1s is the one time password that your RSA SecurID token generates and you enter.

### Using the SecurID user group for authentication

You can use the SecurID user group in several FortiOS features that authenticate by user group including

- [Security policy](#)
- [IPsec VPN XAuth](#)
- [PPTP VPN](#)
- [SSL VPN](#)

The following sections assume the SecurID user group is called `securIDgrp` and has already been configured. Unless otherwise states, default values are used.

## Security policy

To use SecurID in a security policy, you must include the SecurID user group in a security policy. This procedure will create a security policy that allows HTTP, FTP, and POP3 traffic from the `internal` interface to `wan1`. If these interfaces are not available on your FortiGate unit, substitute other similar interfaces.

### To configure a security policy with SecurID authentication

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Enter:

<b>Incoming Interface</b>	internal
<b>Source Address</b>	all
<b>Source User(s)</b>	securIDgrp
<b>Outgoing Interface</b>	wan1
<b>Destination Address</b>	all
<b>Schedule</b>	always
<b>Services</b>	HTTP, FTP, POP3
<b>Action</b>	ACCEPT
<b>NAT</b>	On
<b>Shared Shaper</b>	On, if you want to either limit traffic or guarantee minimum bandwidth for traffic that uses the SecurID security policy. Use the default shaper <b>guarantee-100kbps</b> .
<b>Log Allowed Traffic</b>	On, if you want to generate usage reports on traffic authenticated with this policy.

4. Select **OK**.  
The SecurID security policy is configured.

For more detail on configuring security policies, see the FortiOS Handbook FortiGate Fundamentals guide.

## IPsec VPN XAuth

Extended Authentication (XAuth) increases security by requiring user authentication in addition to the preshared key.

When creating an IPsec VPN using the wizard, under **VPN > IPsec Wizard**, select the SecurID **User Group** on the Authentication page. Members of the SecurID group are required to enter their SecureID code to authenticate.

For more on XAuth, see [Configuring XAuth authentication on page 457](#)

## PPTP VPN

PPTP VPN is configured in the CLI. In the PPTP configuration (`config vpn pptp`), set `usrgrp` to the SecurID user group.

## SSL VPN

You need to map the SecurID user group to the portal that will serve SecurID users and include the SecurID user group in the **Source User(s)** field in the security policy.

**To map the SecurID group to an SSL VPN portal:**

1. Go to **VPN > SSL-VPN Settings**.
2. In **Authentication/Portal Mapping**, select **Create New**.
3. Enter

<b>Users/Groups</b>	securIDgrp
<b>Portal</b>	Choose the portal.

4. Select **OK**.

## Users and user groups

FortiGate authentication controls system access by user group. By assigning individual users to the appropriate user groups you can control each user's access to network resources. The members of user groups are user accounts, of which there are several types. Local users and peer users are defined on the FortiGate unit. User accounts can also be defined on remote authentication servers.

This section describes how to configure local users and peer users and then how to configure user groups. For information about configuration of authentication servers see [Authentication servers on page 384](#).

This section contains the following topics:

- [Users](#)
- [User groups](#)

### Users

A user is a user account consisting of username, password, and in some cases other information, configured on the FortiGate unit or on an external authentication server. Users can access resources that require authentication only if they are members of an allowed user group. There are several different types of user accounts with slightly different methods of authentication:

User type	Authentication
<b>Local user</b>	The username and password must match a user account stored on the FortiGate unit. Authentication by FortiGate security policy.
<b>Remote user</b>	The username must match a user account stored on the FortiGate unit and the username and password must match a user account stored on the remote authentication server. FortiOS supports LDAP, RADIUS, and TACACS+ servers.
<b>Authentication server user</b>	A FortiGate user group can include user accounts or groups that exist on a remote authentication server.
<b>FSSO user</b>	With Fortinet Single Sign On (FSSO), users on a Microsoft Windows or Novell network can use their network authentication to access resources through the FortiGate unit. Access is controlled through FSSO user groups which contain Windows or Novell user groups as their members.
<b>PKI or Peer user</b>	A Public Key Infrastructure (PKI) or peer user is a digital certificate holder who authenticates using a client certificate. No password is required, unless two-factor authentication is enabled.
<b>IM Users</b>	IM users are not authenticated. The FortiGate unit can allow or block each IM user name from accessing the IM protocols. A global policy for each IM protocol governs access to these protocols by unknown users.
<b>Guest Users</b>	Guest user accounts are temporary. The account expires after a selected period of time.

This section includes:

- [Local and remote users](#)
- [PKI or peer users](#)
- [Two-factor authentication](#)
- [FortiToken](#)
- [Monitoring users](#)

## Local and remote users

Local and remote users are defined on the FortiGate unit in **User & Device > User Definition**.

<b>Create New</b>	Creates a new user account. When you select <b>Create New</b> , you are automatically redirected to the User Creation Wizard.
<b>Edit User</b>	Modifies a user's account settings. When you select <b>Edit</b> , you are automatically redirected to the Edit User page.
<b>Delete</b>	<p>Removes a user from the list. Removing the user name removes the authentication configured for the user.</p> <p>The <b>Delete</b> icon is not available if the user belongs to a user group.</p> <p>To remove multiple local user accounts from within the list, on the User page, in each of the rows of user accounts you want removed, select the check box and then select <b>Delete</b>.</p> <p>To remove all local user accounts from the list, on the User page, select the check box in the check box column and then select <b>Delete</b>.</p>
<b>User Name</b>	The user name. For a remote user, this username must be identical to the username on the authentication server.
<b>Type</b>	Local indicates a local user authenticated on the FortiGate unit. For remote users, the type of authentication server is shown: LDAP, RADIUS, or TACACS+.
<b>Two-factor Authentication</b>	Indicates whether two-factor authentication is configured for the user.
<b>Ref.</b>	<p>Displays the number of times this object is referenced by other objects. Select the number to open the Object Usage window and view the list of referring objects. The list is grouped into expandable categories, such as Firewall Policy. Numbers of objects are shown in parentheses.</p> <p>To view more information about the referring object, use the icons:</p> <ul style="list-style-type: none"> <li>• <b>View the list page for these objects</b> – available for object categories. Goes to the page where the object is listed. For example, if the category is User Groups, opens User Groups list.</li> <li>• <b>Edit this object</b> – opens the object for editing.</li> <li>• <b>View the details for this object</b> – displays current settings for the object.</li> </ul>

**To create a local or remote user account - web-based manager:**

1. Go to **User & Device > User Definition** and select **Create New**.
2. On the **Choose User Type** page select:

<b>Local User</b>	Select to authenticate this user using a password stored on the FortiGate unit.
<b>Remote RADIUS User</b> <b>Remote TACACS+ User</b> <b>Remote LDAP User</b>	To authenticate this user using a password stored on an authentication server, select the type of server and then select the server from the list. You can select only a server that has already been added to the FortiGate unit configuration.

3. Select **Next** and provide user authentication information.  
For a local user, enter the **User Name** and **Password**.  
For a remote user, enter the **User Name** and the server name.
4. Select **Next** and enter **Contact Information**.  
If email or SMS is used for two-factor authentication, provide the email address or SMS cell number at which the user will receive token password codes. If a custom SMS service is used, it must already be configured. See [FortiToken on page 417](#).
5. Select **Next**, then on the **Provide Extra Info** page enter

<b>Two-factor Authentication</b>	Select to enable two-factor authentication. Then select the Token (FortiToken or FortiToken Mobile) for this user account. See <a href="#">Associating FortiTokens with accounts on page 420</a> .
<b>User Group</b>	Select the user groups to which this user belongs.

6. Select **Create**.

**To create a local user - CLI example:**

Locally authenticated user

```
config user local
  edit user1
    set type password
    set passwd ljt_pj2gpepfdw
  end
```

**To create a remote user - CLI example:**

```
config user local
  edit user2
    set type ldap
    set ldap_server ourLDAPsrv
  end
```

For a RADIUS or TACACS+ user, set `type` to `radius` or `tacacs+`, respectively.

**To create a user with FortiToken Mobile two-factor authentication - CLI example:**

```
config user local
```

```
edit user5
  set type password
  set passwd ljt_pj2gpepfdw
  set two_factor fortitoken
  set fortitoken 182937197
end
```

Remote users are configured for FortiToken two-factor authentication similarly.

### To create a user with SMS two-factor authentication using FortiGuard messaging Service - CLI example:

```
config user local
  edit user6
    set type password
    set passwd 3ww_pjt68dw
    set two_factor sms
    set sms-server fortiguard
    set sms-phone 1365984521
  end
```

## Removing users

Best practices dictate that when a user account is no longer in use, it should be deleted. Removing local and remote users from FortiOS involve the same steps.

If the user account is referenced by any configuration objects, those references must be removed before the user can be deleted. See [Removing references to users on page 413](#).

### To remove a user from the FortiOS configuration - web-based manager:

1. Go to **User & Device > User Definition**.
2. Select the check box of the user that you want to remove.
3. Select **Delete**.
4. Select **OK**.

### To remove a user from the FortiOS configuration - CLI example:

```
config user local
  delete user4444
end
```

## Removing references to users

You cannot remove a user that belongs to a user group. Remove the user from the user group first, and then delete the user.

### To remove references to a user - web-based manager

1. Go to **User & Device > User Definition**.
2. If the number in the far right column for the selected user contains any number other than zero, select it.
3. A more detailed list of object references to this user is displayed. Use its information to find and remove these references to allow you to delete this user.

## PKI or peer users

A PKI, or peer user, is a digital certificate holder. A PKI user account on the FortiGate unit contains the information required to determine which CA certificate to use to validate the user's certificate. Peer users can be included in firewall user groups or peer certificate groups used in IPsec VPNs. For more on certificates, see [Certificates overview on page 470](#).

To define a peer user you need:

- a peer username
- the text from the subject field of the user's certificate, or the name of the CA certificate used to validate the user's certificate

## Creating a peer user

The peer user can be configured only in the CLI.

### To create a peer user for PKI authentication - CLI example:

```
config user peer
edit peer1
set subject peer1@mail.example.com
set ca CA_Cert_1
end
```

There are other configuration settings that can be added or modified for PKI authentication. For example, you can configure the use of an LDAP server to check access rights for client certificates. For information about the detailed PKI configuration settings, see the FortiGate CLI Reference.

## Two-factor authentication

The standard logon requires a username and password. This is one factor authentication—your password is one piece of information you need to know to gain access to the system.

Two factor authentication adds the requirement for another piece of information for your logon. Generally the two factors are something you know (password) and something you have (certificate, token, etc.). This makes it harder for a hacker to steal your logon information. For example if you have a FortiToken device, the hacker would need to both use it and know your password to gain entry to your account.

Two-factor authentication is available on both user and admin accounts. But before you enable two-factor authentication on an administrator account, you need to ensure you have a second administrator account configured to guarantee administrator access to the FortiGate unit if you are unable to authenticate on the main admin account for some reason.

Two-factor authentication does not work with explicit proxies.

---

The methods of two-factor authentication include:

- [Certificate](#)
- [Email](#)

- [SMS](#)
- [FortiToken](#)

### Certificate

You can increase security by requiring both certificate and password authentication for PKI users. Certificates are installed on the user's computer. Requiring a password also protects against unauthorized use of that computer.

Optionally peer users can enter the code from their FortiToken instead of the certificate.

#### To create a peer user with two-factor authentication - CLI example

```
config user peer
  edit peer1
    set subject E=peer1@mail.example.com
    set ca CA_Cert_1
    set two-factor enable
    set passwd fdktguefheygfe
  end
```

For more information on certificates, see [Certificates overview on page 470](#).

### Email

Two-factor email authentication sends a randomly generated six digit numeric code to the specified email address. Enter that code when prompted at logon. This token code is valid for 60 seconds. If you enter this code after that time, it will not be accepted.

A benefit is that you do not require mobile service to authenticate. However, a potential issue is if your email server does not deliver the email before the 60 second life of the token expires.

The code will be generated and emailed at the time of logon, so you must have email access at that time to be able to receive the code.

#### To configure an email provider - web-based manager:

1. Go to **System > Advanced** and enable **Use Custom Email Server** under **Email Service**.
2. Enter **SMTP Server** and **Default Reply To** address.
3. If applicable, enable **Authentication** and enter the **SMTP User** and **Password** to use.
4. Select a **Security Mode**, options are: **None**, **SMTPS** or **STARTTLS**.
5. Enter the **Port** number, the default is 25.
6. Select **Apply**.

#### To configure an email provider - CLI:

```
config system email-server
  set server <server_domain-name>
  set reply-to <Recipient_email_address>
end
```

#### To enable email two-factor authentication - web-based manager:

1. To modify an administrator account, go to **System > Administrators**. To modify a user account go to **User & Device > User Definition**.

2. Edit the user account.
3. Enable and enter the user's **Email Address**.
4. Select **Enable Two-factor Authentication**.
5. Select **Email based two-factor authentication**.
6. Select **OK**.

---

If **Email based two-factor authentication** option doesn't appear after selecting **Enable Two-factor Authentication**, you need to enable it via the CLI as follows.

**To enable email two-factor authentication - CLI:**

```
config user local
  edit <user_name>
    set email-to <user_email>
    set two-factor email
  end
```

---

## SMS

SMS two-factor authentication sends the token code in an SMS text message to the mobile device indicated when this user attempts to logon. This token code is valid for 60 seconds. If you enter this code after that time, it will not be accepted. Enter this code when prompted at logon to be authenticated.

SMS two-factor authentication has the benefit that you do not require email service before logging on. A potential issue is if the mobile service provider does not send the SMS text message before the 60 second life of the token expires.

FortiGuard Messaging Service include four SMS Messages at no cost. If you need more, you should acquire a license through [support.fortinet.com](https://support.fortinet.com) or via customer service.

If you do not use the FortiGuard Messaging Service, you need to configure an SMS service.

**To configure an SMS service - CLI:**

```
config system sms-server
  edit <provider_name>
    set mail-server <server_domain-name>
  next
end
```

**To configure SMS two-factor authentication - web-based manager:**

1. To modify an:
  - administrator account, go to **System > Administrators**, or
  - user account go to **User & Device > User Definition**.
2. Edit the user account.
3. Select **SMS** and enter the **Country Dial Code** and **Phone Number**.
4. Select **Enable Two-factor Authentication**, and select the correct **Token**.
5. Select **OK**.

If you have problems receiving the token codes via SMS messaging, contact your mobile provider to ensure you are using the correct phone number format to receive text messages and that your current mobile plan allows text messages.

## FortiToken

FortiToken is a disconnected one-time password (OTP) generator. It is a small physical device with a button that when pressed displays a six digit authentication code. This code is entered with a user's username and password as two-factor authentication. The code displayed changes every 60 seconds, and when not in use the LCD screen is blanked to extend the battery life.

There is also a mobile phone application, FortiToken Mobile, that performs much the same function.

FortiTokens have a small hole in one end. This is intended for a lanyard to be inserted so the device can be worn around the neck, or easily stored with other electronic devices. Do not put the FortiToken on a key ring as the metal ring and other metal objects can damage it. The FortiToken is an electronic device like a cell phone and must be treated with similar care.

Any time information about the FortiToken is transmitted, it is encrypted. When the FortiGate unit receives the code that matches the serial number for a particular FortiToken, it is delivered and stored encrypted. This is in keeping with the Fortinet's commitment to keeping your network highly secured.

FortiTokens can be added to user accounts that are local, IPsec VPN, SSL VPN, and even Administrators. See [Associating FortiTokens with accounts on page 420](#).

A FortiToken can be associated with only one account on one FortiGate unit.

If a user loses their FortiToken, it can be locked out using the FortiGate so it will not be used to falsely access the network. Later if found, that FortiToken can be unlocked on the FortiGate to allow access once again. See [FortiToken maintenance on page 422](#).

There are three tasks to complete before FortiTokens can be used to authenticate accounts:

1. [Adding FortiTokens to the FortiGate](#)
2. [Activating a FortiToken on the FortiGate](#)
3. [Associating FortiTokens with accounts](#)

In addition, this section includes the following:

- [FortiToken maintenance](#)
- [FortiToken Mobile Push](#)

## The FortiToken authentication process

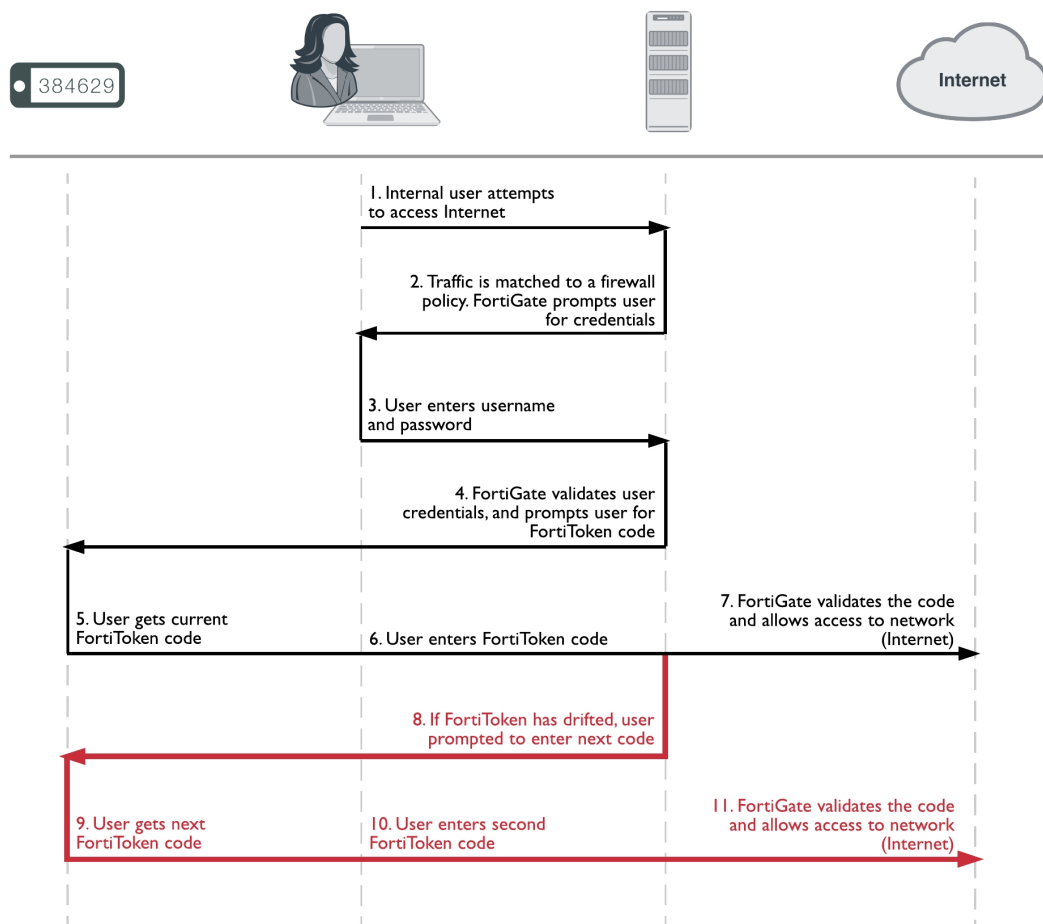

The steps during FortiToken two-factor authentication are as follows.

1. User attempts to access a network resource.
2. FortiGate unit matches the traffic to an authentication security policy, and FortiGate unit prompts the user for username and password.
3. User enters their username and password.
4. FortiGate unit verifies their information, and if valid prompts the user for the FortiToken code.
5. User gets the current code from their FortiToken device.
6. User enters current code at the prompt.
7. FortiGate unit verifies the FortiToken code, and if valid allows access to the network resources such as the Internet.

The following steps are needed only if the time on the FortiToken has drifted and needs to be re-synchronized with the time on the FortiGate unit.

8. If time on FortiToken has drifted, FortiGate unit will prompt user to enter a second code to confirm.
9. User gets the next code from their FortiToken device
10. User enters the second code at the prompt.
11. FortiGate unit uses both codes to update its clock to match the FortiToken and then proceeds as in step "Users and user groups" on page 410.

The FortiToken authentication process is illustrated below:

When configured the FortiGate unit accepts the username and password, authenticates them either locally or remotely, and prompts the user for the FortiToken code. The FortiGate then authenticates the FortiToken code. When FortiToken authentication is enabled, the prompt field for entering the FortiToken code is automatically added to the authentication screens.

Even when an Administrator is logging in through a serial or Telnet connection and their account is linked to a FortiToken, that Administrator will be prompted for the token's code at each login.

If you have attempted to add invalid FortiToken serial numbers, there will be no error message. The serial numbers will simply not be added to the list.

## Adding FortiTokens to the FortiGate

Before one or more FortiTokens can be used to authenticate logons, they must be added to the FortiGate. The import feature is used to enter many FortiToken serial numbers at one time. The serial number file must be a text file with one FortiToken serial number per line.

Both FortiToken Mobile and physical FortiTokens store their encryption seeds on the cloud, therefore you will only be able to register them to a single FortiGate or FortiAuthenticator.

Because FortiToken-200CD seed files are stored on the CD, these tokens can be registered on multiple FortiGates and/or FortiAuthenticators, but **not** simultaneously.

---

### To manually add a FortiToken to the FortiGate - web-based manager:

1. Go to **User & Device > FortiTokens**.
2. Select **Create New**.
3. In **Type**, select **Hard Token** or **Mobile Token**.
4. Enter one or more FortiToken serial numbers (hard token) or activation codes (mobile token).
5. Select **OK**.

For mobile token, you receive the activation code in the license certificate once you purchase a license. FortiOS include a license for two mobile token at no cost.

---

### To import multiple FortiTokens to the FortiGate - web-based manager:

1. Go to **User & Device > FortiTokens**.
2. Select **Create New**.
3. In **Type**, select **Hard Token**.
4. Select **Import**.
5. Select **Serial Number File** or **Seed File**, depending on which file you have.
6. Browse to the local file location on your local computer.
7. Select **OK**.  
The file is imported.
8. Select **OK**.

### To import FortiTokens to the FortiGate from External Sources - CLI:

FortiToken seed files (both physical and mobile versions) can be imported from either FTP or TFTP servers, or a USB drive, allowing seed files to be imported from an external source more easily:

```
execute fortitoken import ftp <file name> <ip>[:ftp port] <Enter> <user> <password>
execute fortitoken import tftp <file name> <ip>
execute fortitoken import usb <file name>
```

To import seed files for FortiToken Mobile, replace `fortitoken` with `fortitoken-mobile`.

### To add two FortiTokens to the FortiGate - CLI:

```
config user fortitoken
  edit <serial_number>
  next
  edit <serial_number2>
  next
end
```

### Activating a FortiToken on the FortiGate

Once one or more FortiTokens have been added to the FortiGate unit, they must be activated before being available to be associated with accounts. The process of activation involves the FortiGate querying FortiGuard servers about the validity of each FortiToken. The serial number and information is encrypted before it is sent for added security.

A FortiGate unit requires a connection to FortiGuard servers to activate a FortiToken.

### To activate a FortiToken on the FortiGate unit - web-based manager:

1. Go to **User & Device > FortiTokens**.
2. Select one or more FortiTokens with a status of Available.
3. Right-click the FortiToken entry and select **Activate**.
4. Select **Refresh**.

The status of selected FortiTokens will change to Activated.

The selected FortiTokens are now available for use with user and admin accounts.

### To activate a FortiToken on the FortiGate unit - CLI:

```
config user fortitoken
  edit <token_serial_num>
    set status activate
  next
end
```

### Associating FortiTokens with accounts

The final step before using the FortiTokens to authenticate logons is associating a FortiToken with an account. The accounts can be local user or administrator accounts.

### To add a FortiToken to a local user account - web-based manager:

1. Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Available.
2. Go to **User & Device > User Definition**, and edit the user account.

3. Enter the user's **Email Address**.
4. Enable **Two-factor Authentication**.
5. Select the user's FortiToken serial number from the **Token** list.
6. Select **OK**.

For mobile token, click on **Send Activation Code** to be sent to the email address configured previously. The user will use this code to activate his mobile token. An **Email Service** has to be set under **System > Advanced** in order to send the activation code.

---

#### To add a FortiToken to a local user account - CLI:

```
config user local
  edit <username>
    set type password
    set passwd "myPassword"
    set two-factor fortitoken
    set fortitoken <serial_number>
    set email-to "username@example.com"
    set status enable
  next
end
```

#### To add a FortiToken to an administrator account - web-based manager:

1. Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Available.
2. Go to **System > Administrators**, and edit the admin account.  
This account is assumed to be configured except for two-factor authentication.
3. Enter admin's **Email Address**.
4. Enable **Two-factor Authentication**.
5. Select the user's FortiToken serial number from the **Token** list.
6. Select **OK**.

For mobile token, click on **Send Activation Code** to be sent to the email address configured previously. The admin will use this code to activate his mobile token. An **Email Service** has to be set under **System > Advanced** in order to send the activation code.

---

#### To add a FortiToken to an administrator account - CLI:

```
config system admin
  edit <username>
    set password "myPassword"
    set two-factor fortitoken
    set fortitoken <serial_number>
    set email-to "username@example.com"
  next
end
```

The `fortitoken` keyword will not be visible until `fortitoken` is selected for the `two-factor` option.

Before a new FortiToken can be used, it may need to be synchronized due to clock drift.

## FortiToken maintenance

Once FortiTokens are entered into the FortiGate unit, there are only two tasks to maintain them — changing the status,

### To change the status of a FortiToken between Activated and Locked - CLI:

```
config user fortitoken
  edit <token_serial_num>
    set status lock
  next
end
```

Any user attempting to login using this FortiToken will not be able to authenticate.

### To list the drift on all FortiTokens configured on this FortiGate unit - CLI:

```
# diag fortitoken info
FORTITOKEN DRIFT STATUS
FTK2000BHV1KRZCC 0 token already activated, and seed won't be returned
FTK2001C5YCRRVEE 0 token already activated, and seed won't be returned
FTKMOB4B94972FBA 0 provisioned
FTKMOB4BA4BE9B84 0 new
Total activated token: 0
Total global activated token: 0
Token server status: reachable
```

This command lists the serial number and drift for each FortiToken configured on this FortiGate unit. This command is useful to check if it is necessary to synchronize the FortiGate and any particular FortiTokens.

## FortiToken Mobile Push

A command under `config system ftm-push` allows you to configure the FortiToken Mobile Push services server IP address and port number. The Push service is provided by Apple (APNS) and Google (GCM) for iPhone and Android smartphones respectively. This will help to avoid tokens becoming locked after an already enabled two-factor authentication user has been disabled.

### CLI syntax

```
config system ftm-push
  set server-ip <ip-address>
  set server-port [1-65535] Default is 4433.
end
```

Note that the `server-ip` is the public IP address of the FortiGate interface that the FTM will call back to; it is the IP address used by the FortiGate for incoming FTM calls.

If an SSL VPN user authenticates with their token, then logs out and attempts to reauthenticate again within a minute, a new message will display showing "Please wait x seconds to login again." This replaces a previous error/permission denied message.

The "x" value will depend on the calculation of how much time is left in the current time step.

### CLI syntax

```
config system interface
  edit <name>
    set allowaccess ftm
  next
end
```

FortiGate supports when the FortiAuthenticator initiates FTM Push notifications, for when users are attempting to authenticate through a VPN and/or RADIUS (with FortiAuthenticator as the RADIUS server).

---

## Monitoring users

To monitor user activity in the web-based manager, go to **Monitor > Firewall User Monitor**. The list of users who are logged on is displayed with some information about them such as their user group, security policy ID, how long they have been logged on, their IP address, traffic volume, and their authentication method as one of FSSO, NTLM, or firewall (FW-auth).

From this screen you can de-authenticate all users who are logged on. The de-authenticate button is at the top left of this screen.

To see information about banned users go to **Monitor > Quarantine Monitor**. Displayed information about users who have been banned includes what application triggered the ban (Application Protocol), the reason for the ban (Cause or rule), Created, and when the ban expires.

### Filtering the list of users

When there are many users logged on, it can be difficult to locate a specific user or multiple users to analyze. Applying filters to the list allows you to organize the user list to meet your needs, or only display some the users that meet your current requirements.

Select settings bottom at the top right of the screen to adjust columns that are displayed for users, including what order they are displayed in. This can be very helpful in locating information you are looking for.

Each column heading has a grey filter icon. Click on the filter icon to configure a filter for the data displayed in that column. Each column has similar options including a field to enter the filtering information, a check box to select the negative of the text in the field, and the options to add more fields, apply the filter, clear all filters, or cancel without saving. To enter multiple terms in the field, separate each of them with a comma. To filter entries that contain a specific prefix, use an \* (asterisk).

For example, to create a filter to display only users with an IP address of 10.11.101.x who authenticated using one of security policies five through eight, and who belong to the user group Accounting.

1. Go to **Monitor > Quarantine Monitor**.
2. Enter 10.11.101.\* and select **Apply**.
3. Select the filter icon beside **Policy ID**.
4. Enter 5-8 and select **Apply**.

5. Select the filter icon beside **User Group**.
6. Enter `Accounting` and select **Apply**.

#### **Login credentials for guest users shown in clear text on GUI and voucher**

In FortiOS 5.6.4, login credentials for guest users is displayed/printed in clear text on the GUI and in the voucher. It is also sent in clear text by SMS and email.

---

## **User groups**

A user group is a list of user identities. An identity can be:

- a local user account (username/password stored on the FortiGate unit)
- a remote user account (password stored on a RADIUS, LDAP, or TACACS+ server)
- a PKI user account with digital client authentication certificate stored on the FortiGate unit
- a RADIUS, LDAP, or TACACS+ server, optionally specifying particular user groups on that server
- a user group defined on an FSSO server.

Security policies and some types of VPN configurations allow access to specified user groups only. This restricted access enforces Role Based Access Control (RBAC) to your organization's network and its resources. Users must be in a group and that group must be part of the security policy.

In most cases, the FortiGate unit authenticates users by requesting their username and password. The FortiGate unit checks local user accounts first. If a match is not found, the FortiGate unit checks the RADIUS, LDAP, or TACACS+ servers that belong to the user group. Authentication succeeds when a matching username and password are found. If the user belongs to multiple groups on a server, those groups will be matched as well.

FortiOS does not allow username overlaps between RADIUS, LDAP, or TACACS+ servers.

---

There are four types of FortiGate user groups: Firewall, Fortinet Single Sign-On (FSSO), Guest, and RADIUS Single Sign-On (RSSO) user groups.

### **Firewall user groups**

Firewall user groups are used locally as part of authentication. When a security policy allows access only to specified user groups, users must authenticate. If the user authenticates successfully and is a member of one of the permitted groups, the session is allowed to proceed.

This section includes:

- [SSL VPN access](#)
- [IPsec VPN access](#)
- [Configuring a firewall user group](#)
- [User group timeouts](#)

## SSL VPN access

SSL VPN settings include a list of the firewall user groups that can access the SSL VPN and the SSL VPN portal that each group will use. When the user connects to the FortiGate unit via HTTPS on the SSL VPN port (default 10443), the FortiGate unit requests a username and password.

SSL VPN access also requires a security policy where the destination is the SSL interface. For more information, see the [FortiOS Handbook SSL VPN](#) guide.

## IPsec VPN access

A firewall user group can provide access for dialup users of an IPsec VPN. In this case, the IPsec VPN phase 1 configuration uses the **Accept peer ID in dialup group** peer option. The user's VPN client is configured with the username as peer ID and the password as pre-shared key. The user can connect successfully to the IPsec VPN only if the username is a member of the allowed user group and the password matches the one stored on the FortiGate unit.

A user group cannot be used as a dialup group if any member of the group is authenticated using an external authentication server.

---

For more information, see the [FortiOS Handbook IPsec VPN](#) guide.

## Configuring a firewall user group

A user group can contain:

- local users, whether authenticated by the FortiGate unit or an authentication server
- PKI users
- authentication servers, optionally specifying particular user groups on the server

### To create a Firewall user group - web-based manager:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a name for the user group.
3. In **Type**, select **Firewall**.
4. Add user names to the **Members** list.

5. Add authentication servers to the **Remote groups** list.

By default all user accounts on the authentication server are members of this FortiGate user group. To include only specific user groups from the authentication server, deselect **Any** and enter the group name in the appropriate format for the type of server. For example, an LDAP server requires LDAP format, such as:

cn=users,dn=office,dn=example,dn=com

Remote servers must already be configured in **User & Device**.

6. Select **OK**.

### To create a firewall user group - CLI example:

In this example, the members of `accounting_group` are `User1` and all of the members of `rad_accounting_group` on myRADIUS external RADIUS server.

```
config user group
```

```

edit accounting_group
  set group-type firewall
  set member User1 myRADIUS
  config match
    edit 0
      set server-name myRADIUS
      set group-name rad_accounting_group
    end
  end
end

```

Matching user group names from an external authentication server might not work if the list of group memberships for the user is longer than 8000 bytes. Group names beyond this limit are ignored.

`server_name` is the name of the RADIUS, LDAP, or TACACS+ server, but it must be a member of this group first and must also be a configured remote server on the FortiGate unit.

`group_name` is the name of the group on the RADIUS, LDAP, or TACACS+ server such as “engineering” or “cn=users,dc=test,dc=com”.

Before using group matching with TACACS+, you must first enable authentication. For example if you have a configured TACACS+ server called myTACS, use the following CLI commands.

```

config user tacacs+
  edit myTACS
    set authorization enable
  next
end

```

For more information about user group CLI commands, see the [Fortinet CLI Reference](#).

### User group timeouts

User groups can have timeout values per group in addition to FortiGate-wide timeouts. There are essentially three different types of timeouts that are configurable for user authentication on the FortiGate unit — idle timeout, hard timeout, and session timeout. These are in addition to any external timeouts such as those associated with RADIUS servers.

If VDOMs are enabled, the global level user setting `authtimeout` is the default all VDOMs inherit. If VDOMs are not enabled, user settings `authtimeout` is the default. The default timeout value is used when the `authtimeout` keyword for a user group is set to zero.

Each type of timeout will be demonstrated using the existing user group `example_group`. Timeout units are minutes. A value of zero indicates the global timeout is used.

### Membership in multiple groups

When a user belongs to multiple groups in RADIUS groups, the group auth-timeout values are ignored. Instead the global timeout value is used. The default value is 5 minutes, but it can be set from 1 to 43200 minutes (30 days).

```

config user setting
  set auth-timeout-type idle-timeout
  set auth-timeout 300
end

```

### Idle timeout

The default type of timeout is idle timeout. When a user initiates a session, it starts a timer. As long as data is transferred in this session, the timer continually resets. If data flow stops, the timer is allowed to advance until it reaches its limit. At that time the user has been idle for too long, and the user is forced to re-authenticate before traffic is allowed to continue in that session.

#### To configure user group authentication idle timeout - CLI:

```
config user settings
    set auth-timeout-type idle-timeout
end
config user group
    edit example_group
        set authtimeout 5 //range is 0-43200 minutes (0 = use global authtimeout value)
    next
end
```

### Hard timeout

Where the idle timeout is reset with traffic, the hard timeout is absolute. From the time the first session a user establishes starts, the hard timeout counter starts. When the timeout is reached, all the sessions for that user must be re-authenticated. This timeout is not affected by any event.

#### To configure user group authentication hard timeout - CLI:

```
config user settings
    set auth-timeout-type hard-timeout
end
config user group
    edit example_group
        set authtimeout 43200 //range is 0-43200 minutes (0 = use global authtimeout value)
    next
end
```

### Session timeout

The session timeout works much like the hard timeout in that its an absolute timer that can not be affected by events. However, when the timeout is reached existing sessions may continue but new sessions are not allowed until re-authentication takes place.

#### To configure a user group authentication new session hard timeout - CLI:

```
config user setting
    set auth-timeout-type new-session
end

config user group
    edit example_group
        set authtimeout 30 //range is 0-43200 minutes (0 = use global authtimeout value)
    next
end
```

## SSO user groups

SSO user groups are part of FSSO authentication and contain only Windows or Novell network users. No other user types are permitted as members. Information about the Windows or Novell user groups and the logon activities of their members is provided by the Fortinet Single Sign On (FSSO) which is installed on the network domain controllers.

You can specify FSSO user groups in security policies in the same way as you specify firewall user groups. FSSO user groups cannot have SSL VPN or dialup IPsec VPN access.

For information about configuring FSSO user groups, see [Creating Fortinet Single Sign-On \(FSSO\) user groups on page 540](#). For complete information about installing and configuring FSSO, see [Agent-based FSSO on page 503](#).

## Configuring Peer user groups

Peer user groups can only be configured using the CLI. Peers are digital certificate holders defined using the `config user peer` command. The peer groups you define here are used in dialup IPsec VPN configurations that accept RSA certificate authentication from members of a peer certificate group.

### To create a peer group - CLI

```
config user peergrp
  edit vpn_peergrp1
    set member pki_user1 pki_user2 pki_user3
  end
```

## Viewing, editing and deleting user groups

To view the list of FortiGate user groups, go to **User & Device > User Groups**.

### Editing a user group

When editing a user group in the CLI you must set the type of group this will be — either a firewall group, a Fortinet Single Sign-On Service group (FSSO), a Radius based Single Sign-On Service group (RSSO), or a guest group. Once the type of group is set, and members are added you cannot change the group type without removing the members.

In the web-based manager, if you change the type of the group any members will be removed automatically.

### To edit a user group - web-based manager

1. Go to **User & Device > User Groups**.
2. Select the user group that you want to edit.
3. Select the **Edit** button.
4. Modify the user group as needed.
5. Select **OK**.

### To edit a user group - CLI

This example adds user3 to Group1. Note that you must re-specify the full list of users:

```
config user group
  edit Group1
    set group-type firewall
```

```
    set member user2 user4 user3
end
```

### Deleting a user group

Before you delete a user group, you must ensure there are no objects referring to it such as security policies. If there are, you must remove those references before you are able to delete the user group.

#### To remove a user group - web-based manager

1. Go to **User & Device > User Groups**.
2. Select the user group that you want to remove.
3. Select the **Delete** button.
4. Select **OK**.

#### To remove a user group - CLI

```
config user group
    delete Group2
end
```

### SSL renegotiation in firewall authentication

The `auth-ssl-allow-renegotiation` option is available under `config user setting` to allow/forbid SSL renegotiation in firewall authentication. The default value is `disable`, where a session would be terminated by `authd` once renegotiation is detected and this login would be recorded as a failure. Other behavior follows regular authentication settings.

#### To enable SSL renegotiation - CLI

```
config user setting
    set auth-ssl-allow-renegotiation enable
end
```

## Managing Guest Access

Visitors to your premises might need user accounts on your network for the duration of their stay. If you are hosting a large event such as a conference, you might need to create many such temporary accounts. The FortiOS Guest Management feature is designed for this purpose.

A guest user account User ID can be the user's email address, a randomly generated string, or an ID that the administrator assigns. Similarly, the password can be administrator-assigned or randomly generated.

You can create many guest accounts at once using randomly-generated User IDs and passwords. This reduces administrator workload for large events.

### User's view of guest access

1. The user receives an email, SMS message, or printout from a FortiOS administrator listing a User ID and password.
2. The user logs onto the network with the provided credentials.
3. After the expiry time, the credentials are no longer valid.

### Administrator's view of guest access

1. Create one or more guest user groups.  
All members of the group have the same characteristics: type of User ID, type of password, information fields used, type and time of expiry.
2. Create guest accounts using Guest Management.
3. Use captive portal authentication and select the appropriate guest group.

## Configuring guest user access

To set up guest user access, you need to create at least one guest user group and add guest user accounts. Optionally, you can create a guest management administrator whose only function is the creation of guest accounts in specific guest user groups. Otherwise, any administrator can do guest management.

### Creating guest management administrators

To create a guest management administrator

1. Go to **System > Administrators** and create a regular administrator account.  
For detailed information see the [System Administration](#) chapter.
2. Select **Restrict to Provision Guest Accounts**.
3. In **Guest Groups**, add the guest groups that this administrator manages.

### Creating guest user groups

The guest group configuration determines the fields that are provided when you create a guest user account.

**To create a guest user group:**

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information:

<b>Name</b>	Enter a name for the group.
<b>Type</b>	Guest
<b>Enable Batch Account Creation</b>	<p>Create multiple accounts automatically. When this is enabled:</p> <ul style="list-style-type: none"> <li>• <b>User ID</b> and <b>Password</b> are set to <b>Auto-Generate</b>.</li> <li>• The user accounts have only <b>User ID</b>, <b>Password</b>, and <b>Expiration</b> fields. Only the <b>Expiration</b> field is editable. If the expiry time is a duration, such as “8 hours”, this is the time after first login.</li> <li>• You can print the account information. Users do not receive email or SMS notification.</li> </ul> <p>See <a href="#">To create multiple guest user accounts automatically on page 432</a>.</p>
<b>User ID</b>	<p>Select one of:</p> <ul style="list-style-type: none"> <li>• Email — User’s email address</li> <li>• Specify — Administrator assigns user ID</li> <li>• Auto-Generate — FortiGate unit creates a random user ID</li> </ul>
<b>Password</b>	<p>Select one of:</p> <ul style="list-style-type: none"> <li>• Specify — Administrator assigns user ID</li> <li>• Auto-Generate — FortiGate unit creates a random password</li> <li>• Disable — no password</li> </ul>
<b>Expire Type</b>	<p>Choose one of:</p> <ul style="list-style-type: none"> <li>• Immediately — expiry time is counted from creation of account</li> <li>• After first login — expiry time is counted from user’s first login</li> </ul>
<b>Default Expire Time</b>	Set the expire time. The administrator can change this for individual users.
<b>Enable Name</b>	If enabled, user must provide a name.
<b>Enable Sponsor</b>	If enabled, user form has Sponsor field. Select <b>Required</b> if required.
<b>Enable Company</b>	If enabled, user form has Company field. Select <b>Required</b> if required.
<b>Enable Email</b>	If enabled, user is notified by email.
<b>Enable SMS</b>	If enabled, user is notified by SMS. Select whether FortiGuard Messaging Service or a another SMS provider is used.

## Creating guest user accounts

Guest user accounts are not the same as local user accounts created in **User & Device > User Definition**. Guest accounts are not permanent; they expire after a defined time period. You create guest accounts in **User & Device > Guest Management**.

### To create a guest user account

1. Go to **User & Device > Guest Management**.
2. In **Guest Groups**, select the guest group to manage.
3. Select **Create New** and fill in the fields in the **New User** form.

Fields marked Optional can be left blank. The guest group configuration determines the fields that are available.

4. Select **OK**.

#### To create multiple guest user accounts automatically

1. Go to **User & Device > Guest Management**.
2. In **Guest Groups**, select the guest group to manage.  
The guest group must have the **Enable Batch Guest Account Creation** option enabled.
3. Select **Create New > Multiple Users**.  
Use the down-pointing caret to the right of **Create New**.
4. Enter **Number of Accounts**.
5. Optionally, change the **Expiration**.
6. Select **OK**.

#### Guest Management Account List

Go to **User & Device > Guest Management** to create, view, edit or delete guest user accounts.

<b>Create New</b>	Creates a new guest user account.
<b>Edit</b>	Edit the selected guest user account.
<b>Delete</b>	Delete the selected guest user account.
<b>Purge</b>	Remove all expired accounts from the list.
<b>Send</b>	Send the user account information to a printer or to the guest. Depending on the group settings and user information, the information can be sent to the user by email or SMS.
<b>Refresh</b>	Update the list.
<b>Guest Groups</b>	Select the guest group to list. New accounts are added to this group.
<b>User ID</b>	The user ID. Depending on the guest group settings, this can be the user's email address, an ID that the administrator specified, or a randomly-generated ID.
<b>Expires</b>	Indicates a duration such as "3 hours". A duration on its own is relative to the present time. Or, the duration is listed as "after first login."

#### Guest access in a retail environment

Some retail businesses such as coffee shops provide free Wi-Fi Internet access for their customers. For this type of application, the FortiOS guest management feature is not required; the Wi-Fi access point is open and customers do not need logon credentials. However, the business might want to contact its customers later with promotional offers to encourage further patronage. Using an Email Collection portal, it is possible to collect customer email addresses for this purpose. The security policy grants network access only to users who provide a valid email address.

The first time a customer's device attempts to use the Wi-Fi connection, FortiOS requests an email address, which it validates. The customer's subsequent connections go directly to the Internet without interruption.

### Creating an email harvesting portal

The customer's first contact with your network will be with a captive portal which presents a web page requesting an email address. When FortiOS has validated the email address, the customer's device MAC address is added to the Collected Emails device group.

#### To create the email collection portal:

1. Go to **WiFi & Switch Controller > SSID** and edit your SSID.
2. Set **Security Mode** to **Captive Portal**.
3. Set **Portal Type** to **Email Collection**.
4. Optionally, in **Customize Portal Messages** select **Email Collection**.

You can change the portal content and appearance. See [Customizing captive portal pages on page 463](#).

#### To create the email collection portal - CLI:

In this example the `freewifi` Wi-Fi interface is modified to present an email collection captive portal.

```
config wireless-controller vap
  edit freewifi
    set security captive-portal
    set portal-type email-collect
  end
```

### Creating the security policy

You need configure a security policy that allows traffic to flow from the Wi-Fi SSID to the Internet interface but only for members of the Collected Emails device group. This policy must be listed first. Unknown devices are not members of the Collected Emails device group, so they do not match the policy.

#### To create the security policy:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information:

<b>Incoming Interface</b>	freewifi
<b>Source Address</b>	all
<b>Source Device Type</b>	Collected Emails
<b>Outgoing Interface</b>	wan1
<b>Destination Address</b>	all
<b>Schedule</b>	always
<b>Service</b>	ALL

<b>Action</b>	ACCEPT
<b>NAT</b>	On

3. Select **OK**.

#### To create the authentication rule - CLI:

```
config firewall policy
edit 3
    set srcintf "freewifi"
    set dstintf "wan1"
    set srcaddr "all"
    set action accept
    set devices collected-emails
    set nat enable
    set schedule "always"
    set service "ALL"
end
```

#### Checking for harvested emails

In the web-based manager, go to **User & Device > Device Inventory**. In the CLI you can use the `diagnose user device list` command. For example,

```
FGT-100D # diagnose user device list
hosts
vd 0 d8:d1:cb:ab:61:0f gen 35 req 30 redir 1 last 43634s 7-11_2-int
ip 10.0.2.101 ip6 fe80::dad1:cbff:feab:610f
type 2 'iPhone' src http c 1 gen 29
os 'iPhone' version 'iOS 6.0.1' src http id 358 c 1
email 'yo@yourdomain.com'
vd 0 74:e1:b6:dd:69:f9 gen 36 req 20 redir 0 last 39369s 7-11_2-int
ip 10.0.2.100 ip6 fe80::76e1:b6ff:fedd:69f9
type 1 'iPad' src http c 1 gen 5
os 'iPad' version 'iOS 6.0' src http id 293 c 1
host 'Joes's-iPad' src dhcp
email 'you@fortinet.com'
```

#### Fall-through authentication policies

User authentication policies have an implicit fall-through feature that intentionally causes policy matching to fall through to a policy lower on the list that can also match the traffic. In other words the first user policy that is matched in the policy list, based on standard policy criteria, isn't the only policy that can be matched.

Fall-through is intended to match users in different user groups with different policies. For example, consider an organization with two user groups where one group requires a web filtering profile, while the other requires virus scanning. In this example, you would edit two basic Internet access policies: policy 1 assigning **User Group A** with a **Web Filtering** profile, and policy 2 assigning **User Group B** with an **AntiVirus** profile. Both policies are also assigned to the same internal subnet, named **subnet1**.

In this configuration, all users from **subnet1** will see an authentication prompt. If the user is found in **User Group A**, the traffic is accepted by policy 1 and is filtered by the **Web Filtering** profile. If the user is found in **User Group B**, the traffic is accepted by policy 2 and is virus scanned.

The fall-through feature is required for users to be matched with policy 2. Without the fall-through feature, traffic would never be matched with policy 2.

## Configuring authenticated access

When you have configured authentication servers, users, and user groups, you are ready to configure security policies and certain types of VPNs to require user authentication.

This section describes:

- [Authentication timeout](#)
- [Password policy](#)
- [Authentication protocols](#)
- [Authentication in Captive Portals](#)
- [Authentication in security policies](#)
- [Authentication replacement messages](#)
- [VPN authentication](#)

### Authentication timeout

An important feature of the security provided by authentication is that it is temporary—a user must re-authenticate after logging out. Also if a user is logged on and authenticated for an extended period of time, it is a good policy to have them re-authenticate at set periods. This ensures a user's session is cannot be spoofed and used maliciously for extended periods of time — re-authentication will cut any spoof attempts short. Shorter timeout values are more secure.

#### Security authentication timeout

You set the security user authentication timeout to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 4320 minutes (72 hours).

**To set the security authentication timeout - web-based manager:**

1. Go to **User & Device > Authentication Settings**.
2. Enter the **Authentication Timeout** value in minutes.  
The default authentication timeout is 5 minutes.
3. Select **Apply**.

#### SSL VPN authentication timeout

You set the SSL VPN user authentication timeout (**Idle Timeout**) to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 259 200 seconds. The default timeout is 300 seconds.

**To set the SSL VPN authentication timeout - web-based manager:**

1. Go to **VPN > SSL-VPN Settings**.
2. Under **Idle Logout**, make sure that **Logout users when inactive for specified period** is enabled and enter the **Inactive For** value (seconds).
3. Select **Apply**.

## Password policy

Password authentication is effective only if the password is sufficiently strong and is changed periodically. By default, the FortiGate unit requires only that passwords be at least eight characters in length, but up to 128 characters is permitted. You can set a password policy to enforce higher standards for both length and complexity of passwords. Password policies can apply to administrator passwords or IPsec VPN preshared keys.

To set a password policy in the web-based manager, go to **System > Settings**. In the CLI, use the `config system password-policy` command.

Users usually create passwords composed of alphabetic characters and perhaps some numbers. Password policy can require the inclusion of uppercase letters, lowercase letters, numerals or punctuation characters.

### Configuring password minimum requirement policy

Best practices dictate that passwords include:

- one or more uppercase characters
- one or more lower case characters
- one or more of the numerals
- one or more special characters.

The minimum number of each of these types of characters can be set in both the web-based manager and the CLI.

The following procedures show how to force administrator passwords to contain at least two uppercase, four lower case, two digits, and one special character. Leave the minimum length at the default of eight characters.

#### To change administrator password minimum requirements - web-based manager:

1. Go to **System > Settings**.
2. Select **Enable Password Policy**.
3. Select **Must Contain at Least**.
4. Enter the following information:

<b>Upper Case Letters</b>	2
<b>Lower Case Letters</b>	4
<b>Numbers</b>	2
<b>Special Characters</b>	1

5. Under **Apply Password Policy to**, select **Administrator Password**.
6. Select **Apply**.

#### To change administrator password minimum requirements - CLI:

```
config system password-policy
  set status enable
  set apply-to admin-password
  set min-upper-case-letter 2
  set min-lower-case-letter 4
```

```
set min-number 2
set min-non-alphanumeric 1
set change-4-characters enable
end
```

The `change-4-characters` option forces new passwords to change a minimum of four characters in the old password. Changing fewer characters results in the new password being rejected. This option is only available in the CLI.

### To configure a guest administrator password policy - CLI:

As of FortiOS 5.4, a password policy can also be created for guest administrators. The following command shows all possible commands, which are also available under `config system password-policy`.

```
config system password-policy
  set status {enable | disable} Enable/disable password policy.
  set apply-to {guest-admin-password} Guest admin to which this password policy applies.
  set minimum-length <8-128> Minimum password length.
  set min-lower-case-letter <0-128> Min. lowercase characters in password.
  set min-upper-case-letter <0-128> Min. uppercase characters in password.
  set min-non-alphanumeric <0-128> Min. non-alphanumeric characters in password.
  set min-number <0-128> Min. numeric characters in password.
  set change-4-characters {enable | disable} Enable/disable changing at least 4 characters for new password.
  set expire-status {enable | disable} Enable/disable password expiration.
  set expire-day <1-999> Number of days before password expires.
  set reuse-password {enable | disable} Enable/disable reuse of password.
end
```

## Password best practices

In addition to length and complexity, there are security factors that cannot be enforced in a policy. Guidelines issued to users will encourage proper password habits.

Best practices dictate that password expiration also be enabled. This forces passwords to be changed on a regular basis. You can set the interval in days. The more sensitive the information this account has access to, the shorter the password expiration interval should be. For example 180 days for guest accounts, 90 days for users, and 60 days for administrators.

Avoid:

- real words found in any language dictionary
- numeric sequences, such as “12345”
- sequences of adjacent keyboard characters, such as “qwerty”
- adding numbers on the end of a word, such as “hello39”
- adding characters to the end of the old password, such as “hello39” to “hello3900”
- repeated characters
- personal information, such as your name, birthday, or telephone number.

In the case where the FortiGate is handling multiple keytabs in Kerberos authentication, use different passwords when generating each keytab.

---

## Maximum logon attempts and blackout period

When you logon and fail to enter the correct password you could be a valid user, or a hacker attempting to gain access. For this reason, best practices dictate to limit the number of failed attempts to logon before a blackout period where you cannot logon.

To set a maximum of five failed authentication attempts before the blackout, using the following CLI command:

```
config user setting
    set auth-invalid-max 5
end
```

To set the length of the blackout period to five minutes, or 300 seconds, once the maximum number of failed logon attempts has been reached, use the following CLI command:

```
config user setting
    set auth-blackout-time 300
end
```

## Authentication protocols

When user authentication is enabled on a security policy, the authentication challenge is normally issued for any of the four protocols, HTTP, HTTPS, FTP, and Telnet, which are dependent on the connection protocol. By making selections in the Protocol Support list, the user controls which protocols support the authentication challenge. The user must connect with a supported protocol first, so that they can subsequently connect with other protocols.

For example, if you have selected HTTP, FTP, or Telnet, a username and password-based authentication occurs. The FortiGate unit then prompts network users to input their security username and password. If you have selected HTTPS, certificate-based authentication (HTTPS, or HTTP redirected to HTTPS only) occurs.

FTP and Telnet authentication replacement messages cannot be customized. For HTTP and HTTPS replacement messages see [Authentication replacement messages on page 441](#).

---

For certificate-based authentication, you must install customized certificates on the FortiGate unit and on the browsers of network users. If you do not install certificates on the network user's web browser, the network users may see an SSL certificate warning message and have to manually accept the default FortiGate certificate. The network user's web browser may deem the default certificate as invalid.

When you use certificate authentication, if you do not specify any certificate when you create the security policy, the global settings are used. If you specify a certificate, the per-policy setting will overwrite the global setting. For more information about the use of certification authentication see [Certificate-based authentication on page 469](#).

### To set the authentication protocols

1. Go to **User & Device > Authentication Settings**.
2. In **Protocol Support**, select the required authentication protocols.
3. If using HTTPS protocol support, in **Certificate**, select a Local certificate from the drop-down list.
4. Select **Apply**.

## Authentication in Captive Portals

Network interfaces, including WiFi interfaces, can perform authentication at the interface level using a captive portal — an HTML form that requests the user's name and password. A captive portal is useful where all users connecting to the network interface must authenticate. Optionally, on a WiFi interface, the captive portal can be combined with a terms of service disclaimer to which the user must agree before gaining access. For more information, see [Captive portals on page 461](#).

Once successfully authenticated, the user's session passes to the firewall.

## Authentication in security policies

Security policies control traffic between FortiGate interfaces, both physical interfaces and VLAN subinterfaces. The firewall tries to match the session's user or group identity, device type, destination, etcetera to a security policy. When a match is found, the user connects to the requested destination. If no security policy matches, the user is denied access.

A user who has not already been authenticated by a captive portal, FSSO, or RSSO can match only policies where no user or user group is specified. If no such policy exists, the firewall requests authentication. If the user can authenticate and the session can be matched to a policy, the user connects to the requested destination, otherwise, the user is denied access.

This section includes:

- [Enabling authentication protocols](#)
- [Authentication replacement messages](#)
- [Access to the Internet](#)
- [Configuring authentication security policies](#)
- [Identity-based policy](#)
- [NTLM authentication](#)
- [Certificate authentication](#)
- [Restricting number of concurrent user logons](#)

### Enabling authentication protocols

Users can authenticate using FTP, HTTP, HTTPS, and Telnet. However, these protocols must be enabled first.

Another authentication option is to redirect any attempts to authenticate using HTTP to a more secure channel that uses HTTPS. This forces users to a more secure connection before entering their user credentials.

#### To enable support for authentication protocols - web-based manager:

1. Go to **User & Device > Authentication Settings**.
2. Select one or more of HTTP, HTTPS, FTP, Telnet, or Redirect HTTP Challenge to a Secure Channel (HTTPS). Only selected protocols will be available for use in authentication.
3. Select the **Certificate** to use, for example `Fortinet_Factory`.
4. Select **Apply**.

#### To enable support for authentication protocols - CLI:

```
config user setting
```

```
set auth-type ftp http https telnet
set auth-cert Fortinet_Factory
end
```

As of FortiOS 5.4, the `Fortinet_Factory` certificate has been re-signed with an expiration date of 2038. It is used instead of `Fortinet_Factory2`, which has been removed.

## Authentication replacement messages

A replacement message is the body of a webpage containing a message about a blocked website message, a file too large message, a disclaimer, or even a login page for authenticating. The user is presented with this message instead of the blocked content.

Authentication replacement messages are the prompts a user sees during the security authentication process such as login page, disclaimer page, and login success or failure pages. These are different from most replacement messages because they are interactive requiring a user to enter information, instead of simply informing the user of some event as other replacement messages do.

Replacement messages have a system-wide default configuration, a per-VDOM configuration, and disclaimers can be customized for multiple security policies within a VDOM.

These replacement messages are used for authentication using HTTP and HTTPS. Authentication replacement messages are HTML messages. You cannot customize the security authentication messages for FTP and Telnet.

The authentication login page and the authentication disclaimer include replacement tags and controls not found on other replacement messages.

More information about replacement messages can be found in the `config system replacemsg` section of the [FortiOS CLI Reference](#).

### List of authentication replacement messages

Replacement message name (CLI name)	Description
<b>Login challenge page</b> (auth-challenge-page)	<p>This HTML page is displayed if security users are required to answer a question to complete authentication. The page displays the question and includes a field in which to type the answer. This feature is supported by RADIUS and uses the generic RADIUS challenge-access auth response. Usually, challenge-access responses contain a Reply-Message attribute that contains a message for the user (for example, "Please enter new PIN"). This message is displayed on the login challenge page. The user enters a response that is sent back to the RADIUS server to be verified.</p> <p>The Login challenge page is most often used with RSA RADIUS server for RSA SecurID authentication. The login challenge appears when the server needs the user to enter a new PIN. You can customize the replacement message to ask the user for a SecurID PIN.</p> <p>This page uses the <code>%%QUESTION%%</code> tag.</p>

Replacement message name (CLI name)	Description
<b>Disclaimer page</b>  (auth-disclaimer-page-1) (auth-disclaimer-page-2) (auth-disclaimer-page-3)	<p>This page prompts user to accept the displayed disclaimer when leaving the captive portal to access Internet resources. It is displayed when the captive portal type is <b>Authentication and Disclaimer</b> or <b>Disclaimer Only</b>.</p> <p>In the CLI, the auth-disclaimer-page-2 and auth-disclaimer-page-3 pages seamlessly extend the size of the disclaimer page from 8 192 characters to 16 384 and 24 576 characters respectively. In the web-based manager this is handled automatically.</p> <p>See <a href="#">Disclaimer on page 444</a>.</p>
<b>Email token page</b> (auth-email-token-page)	<p>The page prompting a user to enter their email token. See <a href="#">Email on page 1</a>.</p>
<b>FortiToken page</b> (auth-fortitoken-page)	<p>The page prompting a user to enter their FortiToken code. See <a href="#">FortiToken on page 417</a>.</p>
<b>Keepalive page</b> (auth-keepalive-page)	<p>The HTML page displayed with security authentication keepalive is enabled using the following CLI command:</p> <pre>config system globalset auth-keepalive enable end</pre> <p>Authentication keepalive keeps authenticated firewall sessions from ending when the authentication timeout ends. In the web-based manager, go to <b>User &amp; Device &gt; Authentication Settings</b> to set the <b>Authentication Timeout</b>.</p> <p>This page includes %%TIMEOUT%%.</p>
<b>Login failed page</b> (auth-login-failed-page)	<p>The Disclaimer page replacement message does not re-direct the user to a redirect URL or the security policy does not include a redirect URL. When a user selects the button on the disclaimer page to decline access through the FortiGate unit, the Declined disclaimer page is displayed.</p>
<b>Login page</b> (auth-login-page)	<p>The authentication HTML page displayed when users who are required to authenticate connect through the FortiGate unit using HTTP or HTTPS.</p> <p>Prompts the user for their username and password to login.</p> <p>This page includes %%USERNAMEID%% and %%PASSWORDID%% tags.</p>
<b>Declined disclaimer page</b> (auth-reject-page)	<p>The page displayed if a user declines the disclaimer page. See <a href="#">Disclaimer on page 444</a>.</p>

Replacement message name (CLI name)	Description
<b>SMS Token page</b> (auth-sms-token-page)	The page prompting a user to enter their SMS token. See <a href="#">SMS on page 416</a> .
<b>Success message</b> (auth-success-msg)	The page displayed when a user successfully authenticates. Prompts user to attempt their connection again (as the first was interrupted for authentication).

## Access to the Internet

A policy for accessing the Internet is similar to a policy for accessing a specific network, but the destination address is set to **all**. The destination interface is the one that connects to the Internet Service Provider (ISP). For general purpose Internet access, the Service is set to ALL.

Access to HTTP, HTTPS, FTP and Telnet sites may require access to a domain name service. DNS requests do not trigger authentication. You must configure a policy to permit unauthenticated access to the appropriate DNS server, and this policy must **precede** the policy for Internet access. Failure to do this will result in the lack of a DNS connection and a corresponding lack of access to the Internet.

## Configuring authentication security policies

To include authentication in a security policy, the policy must specify user groups. A security policy can authenticate by certificate, FSSO, and NTLM. The two exceptions to this are RADIUS SSO and FSSO Agents. See [SSO using RADIUS accounting records on page 548](#), and [Introduction to FSSO agents on page 504](#).

Before creating a security policy, you need to configure one or more users or user groups. For more information, see [Users and user groups on page 410](#).

Creating the security policy is the same as a regular security policy except you must select the action specific to your authentication method:

### Authentication methods allowed for each policy Action

Action	Authentication method	Where authentication is used
ACCEPT	FSSO Agent or a security policy that specifies an FSSO user group	<a href="#">Agent-based FSSO on page 503</a> .
	NTLM	See <a href="#">NTLM authentication on page 445</a> .
	Certificates	See <a href="#">Configuring certificate-based authentication on page 482</a> .
	RADIUS SSO	See <a href="#">SSO using RADIUS accounting records on page 548</a> .
DENY	none	none

## Disclaimer

A WiFi or SSL captive portal can include a disclaimer message presented after the user authenticates. The user must agree to the terms of the disclaimer to access network resources.

## Customizing authentication replacement messages

Customizing disclaimers or other authentication replacement messages involves changing the text of the disclaimer message, and possibly the overall appearance of the message.

Changing the disclaimer in **System > Replacement Messages** is not the same as selecting to customize a disclaimer used in a captive portal. The captive portal location is a customized disclaimer that inherits the default format for the disclaimer message, but then can be customized for this portal.

### To customize the disclaimer for a captive portal - web-based manager:

1. Go to **Network > Interfaces**. Either select an existing interface or create a new one.
2. Under **Security Mode**, select **Captive Portal**, and enable **Customize Portal Messages**.
3. Select the **Edit** icon. You can select and edit any of the pages. Change your text or layout as needed.

## Enabling security logging

There are two types of logging that relate to authentication — event logging, and security logging.

When enabled, event logging records system events such as configuration changes, and authentication. To configure event logging, go to **Log & Report > Log Settings** and enable **Event Logging**. Select the events you want to log, such as **User activity event**.

When enabled, security logging will log security profile and security policy traffic.

You must enable logging within a security policy, as well as the options that are applied to a security policy, such as security profiles features. Event logs are enabled within the Event Log page.

For more information on logging, see the FortiOS Log and Reporting guide.

For more information on specific types of log messages, see the FortiOS Log Message Reference.

You need to set the logging severity level to **Notification** when configuring a logging location to record traffic log messages.

---

### To enable logging within an existing security policy - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy**.
2. Expand to reveal the policy list of a policy.
3. Select the security policy you want to enable logging on and then select **Edit**.
4. To log all general firewall traffic, select the check box beside **Log Allowed Traffic**, and choose to enable **Security Events** or **All Sessions**.
5. Select **OK**.

## Identity-based policy

An identity-based policy (IBP) performs user authentication in addition to the normal security policy duties. If the user does not authenticate, access to network resources is refused. This enforces Role Based Access Control (RBAC) to your organization's network and resources.

Identity-based policies also support Single Sign-On operation. The user groups selected in the policy are of the Fortinet Single Sign-On (FSSO) type.

User authentication can occur through any of the following supported protocols, including: HTTP, HTTPS, FTP, and Telnet. The authentication style depends on which of these protocols is included in the selected security services group and which of those enabled protocols the network user applies to trigger the authentication challenge.

For username and password-based authentication (HTTP, FTP, and Telnet) the FortiGate unit prompts network users to enter their username, password, and token code if two-factor authentication is selected for that user account. For certificate-based authentication, including HTTPS or HTTP redirected to HTTPS only, see [Certificate authentication on page 455](#).

With identity-based policies, the FortiGate unit allows traffic that matches the source and destination addresses, device types, and so on. This means specific security policies must be placed **before** more general ones to be effective.

When the identity-based policy has been configured, the option to customize authentication messages is available. This allows you to change the text, style, layout, and graphics of the replacement messages associated with this firewall policy. When enabled, customizing these messages follows the same method as changing the disclaimer. See [Disclaimer on page 444](#).

Types of authentication also available in identity-based policies are

- [NTLM authentication](#)
- [Certificate authentication](#)

## NTLM authentication

NT LAN Manager (NTLM) protocol can be used as a fallback for authentication when the Active Directory (AD) domain controller is unreachable. NTLM uses the web browser to send and receive authentication information. See "NTLM" and "FSSO NTLM authentication support".

### To enable NTLM

1. Edit the policy in the CLI to enable NTLM. For example, if the policy ID is 4:
2. Go to **Policy & Objects > IPv4 Policy** and note the **ID** number of your FSSO policy.
3. The policy must have an FSSO user group as **Source User(s)**. There must be at least one FSSO Collector agent configured on the FortiGate unit.

```
config firewall policy
edit 4
set ntlm enable
end
```

## NTLM guest access

Guest profile access may be granted to users who fail NTLM authentication, such as visitors who have no user credentials on the network. To allow guest user access, edit the FSSO security policy in the CLI, like this:

```
config firewall policy
  edit 4
    set ntlm enable
    set ntlm-guest enable
  end
```

### NTLM enabled browsers - CLI

User agent strings for NTLM enabled browsers allow the inspection of initial HTTP-User-Agent values, so that non-supported browsers are able to go straight to guest access without needlessly prompting the user for credentials that will fail. `ntlm-guest` must be enabled to use this option.

```
config firewall policy
  edit 4
    set ntlm enable
    set ntlm-guest enable
    set ntlm-enabled-browsers <user_agent_string>
  next
end
```

`<user_agent_string>` is the name of the browser that is NTLM enabled. Examples of these values include "MSIE", "Mozilla" (which includes FireFox), and "Opera".

Value strings can be up to 63 characters in length, and may not contain cross site scripting (XSS) vulnerability characters such as brackets. The FortiGate unit prevents use of these characters to prevent exploit of cross site scripting (XSS) vulnerabilities.

## Kerberos authentication for explicit web and transparent web proxy users

Kerberos authentication is a method for authenticating both explicit web proxy and transparent web proxy users. It has several advantages over NTLM challenge response:

- Does not require FSSO/AD agents to be deployed across domains.
- Requires fewer round-trips than NTLM SSO, making it less latency sensitive.
- Is (probably) more scalable than challenge response.
- Uses existing Windows domain components rather than added components.
- NTLM may still be used as a fallback for non-Kerberos clients.

### Enhancements to Kerberos explicit and transparent web proxy

FortiOS 5.6.x authentication is managed by schemes and rules based on protocol and source address. As such, configurable authentication settings have been introduced to enhance authentication.

CLI commands (`config authentication rule`, `scheme`, and `setting`) allow explicit proxy rules and schemes to be created to separate user authentication (e.g. authentication rules and schemes used to match conditions in order to identify users) from user authorization (proxy-based policies with users and/or user groups).

### CLI syntax - config authentication rule

```
config authentication rule
  edit <name>
    set name <name>
    set status {enable|disable}
    set protocol {http|ftp|socks}
    config srcaddr <addr-name or addrgrp-name>
```

```
edit <name>
    set name <ipv4-policy-name>
next
end
config srcaddr6 <addr-name or addrgrp-name>
    edit <name>
        set name <ipv6-policy-name>
    next
end
set ip-based {enable|disable}
set active-auth-method <scheme-name>
set sso-auth-method <scheme-name>
set transaction-based {enable|disable} - basic scheme + session-based
set web-auth-cookie {enable|disable}
set comments <comments>
next
end
```

**Note:** As shown above, HTTP, FTP, and SOCKSv5 authentication protocols are supported for explicit proxy.

Authentication rules are used to receive user-identity, based on the values set for protocol and source address. Having said this, if a rule fails to match based on source address, there will be no other attempt to match the rule, however the next policy will be attempted. This occurs only when:

- there is an authentication rule, but no authentication method has been set (under `config authentication scheme`; see below), so user identity cannot be found.
- the user is successfully matched in the rule, but fails to match the current policy.

Once a rule is positively matched through protocol and/or source address, it must also match the authentication method specified (`active-auth-method` and `sso-auth-method`). These methods point to schemes, as defined under `config authentication scheme`.

### CLI syntax - config authentication scheme

```
config authentication scheme
    edit <name>
        set name <name>
        set method {basic|digest|ntlm|form|negotiate|fsso|rsso}
        set negotiate-ntlm {enable|disable}
        set require-tfa {enable|disable}
        set fsso-guest {enable|disable}
        config user-database
            edit <name>
                set name {local|<ldap-server>|<radius-server>|<fsso-name>|<rsso-name>|<tacacs+-name>}
            next
        end
    next
end
```

Combining authentication rules and schemes, granular control can be exerted over users and IPs, creating an efficient process for users to successfully match a criteria before matching the policy.

Additional options can be set under `config authentication setting`.

### CLI syntax - config authentication setting

```
config authentication setting
```

```

set sso-scheme <scheme-name>
set active-scheme <scheme-name>
set captive-portal <host-name>
set captive-portal-port <tcp-port>
end

```

## Integration of Transparent and Explicit proxy HTTP policy checking

A CLI command, under `config firewall profile-protocol-options`, allows HTTP policy checking to be enable or disabled. When enabled, transparent traffic can be matched in a firewall policy and policy user authentication can occur. In addition, separate SSL inspection policies can be created:

```

config firewall profile-protocol-options
edit <name>
    set http-policy {enable|disable}
end

```

## Internet Service Database in Explicit/Implicit proxy policies

CLI commands, under `config firewall proxy-policy`, implement the Internet Service Database (ISDB) as the webproxy matching factor, and override IP pool is also support:

```

config firewall proxy-policy
edit <name>
    set proxy {explicit-web|transparent-web|ftp|wanopt}
    set dstintf <dst-name>
    set poolname <ip-pool-name>
end

```

## Multiple port/port range support for explicit web and explicit FTP proxy

Multiple port numbers and/or ranges can be set for explicit proxy, specifically for HTTP/HTTPS and FTP. Go to **Network > Explicit Proxy** and configure settings under **Explicit Web Proxy** and **Explicit FTP Proxy**, or under `config web-proxy explicit` in the CLI Console.

### 1. General configuration

#### 1.1 Kerberos environment - Windows server setup

1. Build a Windows 2008 Platform server.
2. Enable domain configuration in windows server (dcpromo).
3. Set the domain name TEST.COM (realm name).

#### 1.2 Create users

- *testuser* is a normal user (could be any existing domain user account).
- *testtgt* is the service name. In this case it should be the FQDN for the explicit proxy Interface, For example the hostname in the client browser proxy config.
- Recommendation: create username all in lowercase (even if against corporate standards).
  - The account only requires “domain users” membership
  - Password set to never expire
  - Set a very strong password

### 1.3 Add FortiGate to DNS

Add the FortiGate FQDN in to the Windows DNS domain, as well as in-addr.arpa

---

For Lab/Testing add the FortiGate Domain name and IP mapping in the hosts file (windows/system32/drivers/etc/hosts). e.g., `TESTFGT.TEST.COM 10.10.1.10`

### 1.4 Generate the Kerberos keytab

Use the *ktpass* command (found on Windows Servers and many domain workstations) to generate the Kerberos keytab.

Example:

```
ktpass -princ HTTP/<domain name of test fgt>@realm -mapuser testfgt -pass <password> -crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

---

In the case where the FortiGate is handling multiple keytabs in Kerberos authentication, use different passwords when generating each keytab.

The ktpass on older Windows servers (i.e. 2003) may not support the “all” crypto option.

---

Example:

```
ktpass -princ HTTP/testfgt.test.com@TEST.COM -mapuser testfgt -pass 12345678 -crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

---

The realm name is always presented in uppercase, and prefixed with the “@” character.

---

### 1.5 Encode base64

Use the *base64* command (available in most Linux distros) command to encode the *fgt.keytab* file. Any LF (Line Feed) need to be deleted from the file.

Example:

```
base64 fgt.keytab > fgt.txt
```

---

Use Notepad++ or some native Linux text editor. Windows Notepad and Wordpad are likely to introduce errors.

---

## 2. FortiGate configuration

### 2.1 Create LDAP Server instance

```
config user ldap
  edit "ldap" <<< Required for authorization
    set server "10.10.1.1" <<< LDAP server IP, normally it should be same as KDC server
    set cnid "cn"
    set dn "dc=test,dc=com"
    set type regular
    set username "CN=admin,CN=Users,DC=test,DC=com" <<< Your domain may require STARTTLS
    set password <FOOS>
  next
end
```

### 2.2 Define Kerberos as an authentication service

```
config user krb-keytab
  edit "http_service"
    set principal "HTTP/testfgt.test.com@TEST.COM" <<< Same as the principal name in 1.4
    set ldap-server "ldap" <<< the defined ldap server for authorization
    set keytab
      "BQIAAABNAAIACKJFUkJFU15DT00ABEhUVFAAG1RPT11fRkdUXzEwMERfQS5CRVJCRVIuQ09NAAAAQA
      AAAAKABcAEJQ10MHgovwplu7XzfENJzw=" <<< base64 encoding keytab data, created in step 1.5
  next
end
```

### 2.3 Create user group(s)

```
config user group <<< the group is used for kerberos authentication
  edit "testgrp"
    set member "ldap"
    config match
      edit 1
        set server-name "ldap" <<< Same as ldap-server option in krb-keytab
        set group-name "CN=Domain Users,CN=Users,DC=TEST,DC=com"
      next
    end
  next
end
```

### 2.4 Create firewall policy

```
config firewall proxy-policy
  edit 1
    set uuid 5e5dd6c4-952c-51e5-b363-120ad77c1414
    set proxy explicit-web
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set groups "CN=USERS LAB.PS FSSO"
  next
end
```

## 2.5 Diagnostics

Once the keytab is imported, check that it has been properly decoded. The filename generated will be relatively random, but should be clearly visible.

```
Artoo-Deetoo (root) # fnsysctl ls -la /tmp/kt
drwxr--r-- 2 0 0 Fri Dec 2 10:06:43 2016 60 .
drwxrwxrwt 22 0 0 Tue Dec 6 14:28:29 2016 3280 ..
-rw-r--r-- 1 0 0 Fri Dec 2 10:06:43 2016 392 1.0.89.keytab
```

---

If there is no file present, then the file hasn't decoded. Check the file for line feeds and try again.

---

## 3. Client side walkthrough

### 3.1 Check Kerberos is working

Log on to the domain by using *testuser*, created in 1.2. Use the *klist* command to list ticket information. In the below example, the client has received *krbtgt*, *CIFS*, and *LDAP* tickets. As there has been no interaction with the FortiGate, there are no references to it.

```
C:\Users\glenk>klist Cached Tickets: (5)

C:\Users\glenk>klist
Cached Tickets: (5)
#0> Client: glenk @ home.local

    Server: krbtgt/HOME.LOCAL @ HOME.LOCAL
    KerbTicket Encryption Type: AES-256-CTS-HMAC-SHA1-96
    Ticket Flags 0x60a00000 -> forwardable forwarded renewable pre_authent
    Start Time: 12/6/2016 14:58:06 (local)
    End Time: 12/7/2016 0:58:04 (local)

Renew Time: 12/13/2016 14:58:04 (local)
Session Key Type: AES-256-CTS-HMAC-SHA1-96
```

### 3.2 Configure client

Set up web-proxy in browser through the FortiGate. This can be achieved via a PAC file or direct browser configuration.

Some Firefox documentation indicates that it is necessary to make manual advanced configuration changes to allow Kerberos authentication work. However, builds 48 (and possibly much earlier) require no additional configuration beyond setting of the proxy server.

### 3.3 Open a connection to the Internet

1. The client accesses the explicit proxy, but a *HTTP 407 Proxy Authentication Required* is returned.
2. As "Negotiate" is set, the client has knowledge of the KRBTGT, it requests a ticket from the KDC with a *krb-tgs-req* message. This includes the REALM (HOME.LOCAL) in the *req-body* section, and the provided instances SNAME and service (in this case, HTTP/artoo-deetoo.home.local).
3. The KDC responds with a next KRB-TGS-REP.

This ticket is then available on the client.

In the example below, the ticket-granted-service has issued Ticket #2.

```
#2> Client: glenk @ home.local
Server: HTTP/artoo-deetoo.home.local @ HOME.LOCAL
KerbTicket Encryption Type: RSADSI RC4-HMAC (NT)
Ticket Flags 0x40a00000 -> forwardable renewable pre_authent
Start Time: 12/6/2016 14:59:45 (local)
End Time: 12/7/2016 0:58:04 (local)
Renew Time: 12/13/2016 14:58:04 (local)
Session Key Type: RSADSI RC4-HMAC (NT)
```

4. The conversation between the client and the proxy continues, as the client responds with the Kerberos ticket in the response.

The whole process takes less than a second to complete. The user should be visible as a FSSO logon in the Web UI.

## Transparent web-proxy Kerberos authentication

Transparent web-proxy is new to FortiOS 5.6, in which the FortiGate can process level 7 policy matching, even when the explicit web-proxy is not enabled on the client's browser. The transparent web-proxy policy is set in proxy-policy too. The policy matching rule is the same as the explicit web-proxy.

In the firewall policy level, transparent web-proxy is regarded as a special UTM. The HTTP/HTTPS traffic matches the firewall policy first, then traffic is redirected to the web-proxy daemon. If the transparent web-proxy feature is disabled, http-policy options in profile-protocol-options is used to enable transparent web-proxy feature.

### IP-based

1. Captive portal and the captive portal port must be configured in transparent web-proxy for support of Kerberos authentication:

```
config authentication setting
    set captive-portal <fqdn-name>
    set captive-portal-port "9998"
end
```

2. Authentication rule, scheme, and krb-keytab need to be configured for Kerberos authentication (note the active-auth-method scheme referenced in the rule):

```
config authentication scheme
    edit <kerberos-scheme>
        set method negotiate
        set negotiate-ntlm <enable>
        set fsso-guest <disable>
    next
end

config authentication rule
    edit <name>
        set status <enable>
        set protocol <http>
        set srcaddr "all"
        set ip-based <enable>
        set active-auth-method <kerberos-scheme>
    next
end

config user krb-keytab
    edit <name>
        set principal "HTTP/TESTFGT.TEST.COM@TEST.COM"
        set ldap-server "ldap"
        set keytab <base64-encoding-keytab-data>
    next
end
```

3. Configure LDAP and user group used for authorization:

```
config user ldap
    edit "ldap"
        set server "10.10.1.1"
        set cnid
        set dn
        set type <regular>
        set username "CN=admin,CN=Users,DC=test,DC=com"
```

```

    set password ENC
    aW5lIAHkPMf4D+ZCKpGMU3x8Fpq0G+7uIbAvpblbXFA5vLfGb4/oRBx+B6R/v+CMCetP84e+Gdz5zEcM
    yOd3cjoBoIhFrpYJfXhRs4lSE0HezeVXfxwTSf5VJG+F11G/G5RpaY+AE8bortC8MBE7P2/uGQocFHu4
    Ilulp5I60Jvyk6Ei3hDZMjTd8iPp5IkRJZVVjQ==
  next
end

config user group
  edit "testgrp"
    set member "ldap"
    config match
      edit "1"
        set server-name "ldap"
        set group-name "CN=Domain Users,CN=Users,DC=TEST,DC=com"
      next
    end
  next
end

```

#### 4. Create proxy-policy, with groups as the authorizing policy-matching element:

```

config firewall proxy-policy
  edit 1
    set uuid 1bbb891a-9cd2-51e7-42ff-d1fa13cac3da
    set proxy explicit-web
    set dstintf "any"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set groups testgrp
  next
end

```

#### 5. UTM must be enabled in the firewall policy to support the transparent web-proxy:

```

config firewall policy
  edit "1"
    set name "policy1"
    set uuid 8a6ceeac-b016-51e6-2b5c-165070d5bf50
    set srcintf "mgmt1"
    set dstintf "mgmt1"
    set srcaddr "all"
    set dstaddr "all"
    set action <accept>
    set schedule "always"
    set service "ALL"
    set utm-status <enable>
    set profile-protocol-options "transparent-web-proxy"
    set ssl-ssh-profile "deep-inspection"
    set nat <enable>
  next
end

config firewall profile-protocol-options
  edit "transparent-web-proxy"
    config http
      set ports "80 8080"
    end
  next
end

```

```
        unset options
        set http-policy enable
        unset post-lang
    end
    ...
next
end
```

### Session-based with web-auth cookie

The web-auth-cookie feature is necessary for session-based authentication under transparent web-proxy.

The configuration is the same as for IP-based authentication, except `ip-based` is disabled in the authentication rule:

```
config authentication rule
    edit "kerberos-rules"
        set status <enable>
        set protocol <http>
        set srcaddr "all"
        set ip-based <disable>
        set active-auth-method <kerberos-scheme>
    next

config authentication setting
    set captive-portal <fqdn-name>
    set captive-portal-port "9998"
end
```

### HTTP tunnel authentication

You can trigger user authentication on HTTP CONNECT request at the policy level. A new CLI entry has been added under `config firewall proxy-policy` which will trigger the authentication process `get-user`, even when there is no user or group configured.

Note that, as shown below, explicit web proxy must be set.

#### Syntax

```
config firewall proxy-policy
    edit {policyid}
        set proxy explicit-web
        set http-tunnel-auth {enable | disable}
    next
end
```

### Certificate authentication

You can configure certificate-based authentication for FortiGate administrators, SSL VPN users, and IPsec VPN users. See [Configuring certificate-based authentication on page 482](#).

Certificates are also inherent to the HTTPS protocol, where the browser validates the server's identity using certificates. A site certificate must be installed on the FortiGate unit and the corresponding Certificate Authority (CA) certificate installed in the web browser.

To force the use of HTTPS, go to **User & Device > Authentication Settings** and select **Redirect HTTP Challenge to a Secure Channel (HTTPS)**.

## Restricting number of concurrent user logons

Some users on your network may often have multiple account sessions open at one time either to the same network resource or accessing to the admin interface on the FortiGate unit.

While there are valid reasons for having multiple concurrent sessions open, hackers also do this to speed up their malicious work. Often a hacker is making multiple attempts to gain access to the internal network or the admin interface of the FortiGate unit, usually from different IP addresses to appear to the FortiGate unit as legitimate users. For this reason, the more concurrent sessions a hacker has open at once, the faster they will achieve their goal.

To help prevent this, you can disallow concurrent administrative access using the same administrator user name. This allows only one session with the same username even if it is from the same IP.

### To disable concurrent administrator sessions - CLI:

```
config system global
    set admin-concurrent disable
end
```

## VPN authentication

All VPN configurations require users to authenticate. Authentication based on user groups applies to:

- SSL VPNs
- PPTP and L2TP VPNs
- an IPsec VPN that authenticates users using dialup groups
- a dialup IPsec VPN that uses XAUTH authentication (Phase 1)

You must create user accounts and user groups before performing the procedures in this section. If you create a user group for dialup IPsec clients or peers that have unique peer IDs, their user accounts must be stored locally on the FortiGate unit. You cannot authenticate these types of users using a RADIUS or LDAP server.

## Configuring authentication of SSL VPN users

The general procedure for authenticating SSL VPN users is:

1. Configure user accounts.
2. Create one or more user groups for SSL VPN users.
3. Enable SSL VPN.
4. Optionally, set inactivity and authentication timeouts.
5. Configure a security policy with the user groups you created for SSL VPN users.  
See FortiOS Handbook SSL VPN guide.

## Configuring authentication timeout

By default, the SSL VPN authentication expires after 8 hours (28 800 seconds). You can change it only in the CLI, and the time entered must be in seconds. The maximum time is 72 hours (259 200 seconds). For example, to change this timeout to one hour, you would enter:

```
config vpn ssl settings
    set auth-timeout 3600
end
```

If you set the authentication timeout (`auth-timeout`) to 0 when you configure the timeout settings, the remote client does not have to re-authenticate unless they log out of the system. To fully take advantage of this setting, the value for `idle-timeout` has to be set to 0 also, so that the client does not time out if the maximum idle time is reached. If the `idle-timeout` is not set to the infinite value, the system will log out if it reaches the limit set, regardless of the `auth-timeout` setting.

## Configuring authentication of remote IPsec VPN users

An IPsec VPN on a FortiGate unit can authenticate remote users through a dialup group. The user account name is the peer ID and the password is the pre-shared key.

Authentication through user groups is supported for groups containing only local users. To authenticate users using a RADIUS or LDAP server, you must configure XAUTH settings. See [Configuring XAuth authentication](#).

### To configure user group authentication for dialup IPsec - web-based manager:

1. Configure the dialup users who are permitted to use this VPN. Create a user group with Type:Firewall and add them to it.  
For more information, see [Users and user groups on page 410](#)
2. Go to **VPN > IPsec Wizard**, select **Remote Access**, choose a name for the VPN, and enter the following information.

<b>Incoming Interface</b>	Select the incoming interface name.
<b>Authentication Method</b>	List of authentication methods available for users. Select <b>Preshared Key</b> and enter the preshared key.
<b>User Group</b>	Select the user group that is to be allowed access to the VPN. The listed user groups contain only users with passwords on the FortiGate unit.

3. Select **Next** and continue configure other VPN parameters as needed.
4. Select **OK**.

### To configure user group authentication for dialup IPsec - CLI example:

The `peer type` and `usrgrp` options configure user group-based authentication.

```
config vpn ipsec phase1
  edit office_vpn
    set interface port1
    set type dynamic
    set psksecret yORRAzltNGhzgtV32jend
    set proposal 3des-sha1 aes128-sha1
    set peer type dialup
    set usrgrp Group1
  end
```

## Configuring XAuth authentication

Extended Authentication (XAuth) increases security by requiring additional user authentication information in a separate exchange at the end of the VPN Phase 1 negotiation. The FortiGate unit asks the user for a username and password. It then forwards the user's credentials (the password is encrypted) to an external RADIUS or LDAP server for verification.

XAuth can be used in addition to or in place of IPsec phase 1 peer options to provide access security through an LDAP or RADIUS authentication server. You must configure a dialup user group whose members are all externally authenticated.

### To configure authentication for a dialup IPsec VPN - web-based manager:

1. Configure the users who are permitted to use this VPN. Create a user group and add the users to the group. For more information, see ["Users and user groups" on page 410](#).
2. Go to **VPN > IPsec Wizard**, select **Remote Access**, choose a name for the VPN, and enter the following information.

<b>Incoming Interface</b>	Select the incoming interface name.
<b>Authentication Method</b>	List of authentication methods available for users. Select <b>Preshared Key</b> and enter the preshared key.
<b>User Group</b>	Select the user group that is to be allowed access to the VPN. The listed user groups contain only users with passwords on the FortiGate unit.

3. Select **Next** and continue configure other VPN parameters as needed.
4. Select **OK**.
5. Go to **VPN > IPsec Tunnels**, edit the Tunnel just created, select **Convert To Custom Tunnel**, and edit **XAUTH** as following:

<b>Type</b>	Select <b>PAP</b> , <b>CHAP</b> , or <b>AUTO</b> . Use CHAP whenever possible. Use PAP with all implementations of LDAP and with other authentication servers that do not support CHAP, including some implementations of Microsoft RADIUS. Use AUTO with the Fortinet Remote VPN Client and where the authentication server supports CHAP but the XAuth client does not.
<b>User Group</b>	Select the user group that is to have access to the VPN. The list of user groups does not include any group that has members whose password is stored on the FortiGate unit.

6. Select **OK**.

For more information about XAUTH configuration, see the IPsec VPN chapter of the FortiOS Handbook.

### To configure authentication for a dialup IPsec VPN - CLI example:

The `xauthtype` and `authusrgrp` fields configure XAuth authentication.

```
config vpn ipsec phase1
  edit office_vpn
    set interface port1
    set type dynamic
    set psksecret yORRAzltNGhzgtV32jend
    set proposal 3des-sha1 aes128-sha1
    set peertype dialup
    set xauthtype pap
    set usrgrp Group1
  end
```

Some parameters specific to setting up the VPN itself are not shown here. For detailed information about configuring IPsec VPNs, see the FortiOS Handbook IPsec VPN guide.

## Configuring authentication of PPTP VPN users and user groups

Configuration of a PPTP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

---

### To configure authentication for a PPTP VPN

1. Configure the users who are permitted to use this VPN. Create a security user group and add them to it. For more information, see [Users and user groups on page 410](#).
2. Configure the PPTP VPN in the CLI as in this example.

```
config vpn pptp
  set status enable
  set sip 192.168.0.100
  set eip 192.168.0.110
  set usrgrp PPTP_Group
end
```

The `sip` and `eip` fields define a range of virtual IP addresses assigned to PPTP clients.

Configure a security policy. The source interface is the one through which the clients will connect. The source address is the PPTP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

## Configuring authentication of L2TP VPN users/user groups

Configuration of a L2TP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

LDAP user authentication is supported for PPTP, L2TP, IPsec VPN, and firewall authentication.

However, with PPTP, L2TP, and IPsec VPN, PAP (Packet Authentication Protocol) is supported, while CHAP (Challenge Handshake Authentication Protocol) is not.

---

### To configure authentication for a L2TP VPN

1. Configure the users who are permitted to use this VPN. Create a user group and add them to it. For more information, see [Users and user groups on page 410](#).
2. Configure the L2TP VPN in the CLI as in this example.

```
config vpn l2tp
  set status enable
  set sip 192.168.0.100
  set eip 192.168.0.110
  set usrgrp L2TP_Group
end
```

The `sip` and `eip` fields define a range of virtual IP addresses assigned to L2TP clients.

3. Configure a security policy. The source interface is the one through which the clients will connect. The source address is the L2TP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

## Captive portals

A captive portal is a convenient way to authenticate web users on wired or WiFi networks.

This section describes:

- [Introduction to Captive portals](#)
- [Configuring a captive portal](#)
- [Customizing captive portal pages](#)

### Introduction to Captive portals

You can authenticate your users on a web page that requests the user's name and password. Until the user authenticates successfully, the authentication page is returned in response to any HTTP request. This is called a captive portal.

After successful authentication, the user accesses the requested URL and can access other web resources, as permitted by security policies. Optionally, the captive portal itself can allow web access to only the members of specified user group.

The captive portal can be hosted on the FortiGate unit or on an external authentication server. You can configure captive portal authentication on any network interface, including WiFi and VLAN interfaces.

When a captive portal is configured on a WiFi interface, the access point initially appears open. The wireless client can connect to the access point with no security credentials, but sees only the captive portal authentication page.

WiFi captive portal types:

- **Authentication** — until the user enters valid credentials, no communication beyond the AP is permitted.
- **Disclaimer + Authentication** — immediately after successful authentication, the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding.
- **Disclaimer Only** — the portal presents the disclaimer page—an acceptable use policy or other legal statement—to which the user must agree before proceeding. The authentication page is not presented.
- **Email Collection** — the portal presents a page requesting the user's email address, for the purpose of contacting the person in future. This is often used by businesses who provide free WiFi access to their customers. The authentication page is not presented.

### Configuring a captive portal

Captive portals are configured on network interfaces. On a physical (wired) network interface, you edit the interface configuration in **Network > Interfaces** and set **Security Mode** to **Captive Portal**. A WiFi interface does not exist until the WiFi SSID is created. You can configure a WiFi captive portal at the time that you create the SSID. Afterwards, the captive portal settings will also be available by editing the WiFi network interface in **Network > Interfaces**.

**To configure a wired Captive Portal - web-based manager:**

1. Go to **Network > Interfaces** and edit the interface to which the users connect.
2. In **Security Mode** select **Captive Portal**.

Security Mode	Captive Portal
Authentication Portal	<input checked="" type="radio"/> Local <input type="radio"/> External
User Groups	Use Groups from Policies
Exempt List	Click to set...
Customize Portal Messages	<input type="checkbox"/>

### 3. Enter

<b>Authentication Portal</b>	Local - portal hosted on the FortiGate unit.  Remote - enter FQDN or IP address of external portal.
<b>User Groups</b>	Select permitted user groups or select <b>Use Groups from Policies</b> , which permits the groups specified in the security policy.  <b>Use Groups from Policies</b> is not available in WiFi captive portals.
<b>Exempt List</b>	Select exempt lists whose members will not be subject to captive portal authentication.
<b>Customize Portal Messages</b>	Enable, then select Edit. See <a href="#">Customizing captive portal pages on page 463</a> .

### 4. Select **OK**.

## To configure a WiFi Captive Portal - web-based manager:

- Go to **WiFi & Switch Controller > SSID** and create your SSID.  
If the SSID already exists, you can edit the SSID or you can edit the WiFi interface in **Network > Interfaces**.
- In **Security Mode**, select **Captive Portal**.

Security Mode	Captive Portal
Portal Type	<input checked="" type="radio"/> Authentication <input type="radio"/> Authentication + Disclaimer <input type="radio"/> Disclaimer Only <input type="radio"/> Email Collection
Authentication Portal	<input checked="" type="radio"/> Local <input type="radio"/> External
User Groups	Use Groups from Policies
Customize Portal Messages	Login Page
Redirect after Captive Portal	<input checked="" type="radio"/> Original Request <input type="radio"/> Specific URL

### 3. Enter

<b>Portal Type</b>	The portal can provide authentication and/or disclaimer, or perform user email address collection. See <a href="#">Introduction to Captive portals on page 461</a> .
<b>Authentication Portal</b>	Local - portal hosted on the FortiGate unit.  Remote - enter FQDN or IP address of external portal.
<b>User Groups</b>	Select permitted user groups.

<b>Exempt List</b>	Select exempt lists whose members will not be subject to captive portal authentication.
<b>Customize Portal Messages</b>	Click the link of the portal page that you want to modify. See " <a href="#">Captive portals</a> " on page 463.

4. Select **OK**.

### Exemption from the captive portal

A captive portal requires all users on the interface to authenticate. But some devices are not able to authenticate. You can create an exemption list of these devices. For example, a printer might need to access the Internet for firmware upgrades. Using the CLI, you can create an exemption list to exempt all printers from authentication.

```
config user security-exempt-list
  edit r_exempt
    config rule
      edit 1
        set devices printer
      end
    end
  end
```

### Customizing captive portal pages

These pages are defined in replacement messages. Defaults are provided. In the web-based manager, you can modify the default messages in the SSID configuration by selecting **Customize Portal Messages**. Each SSID can have its own unique portal content.

The captive portal contains the following default web pages:

- **Login page**—requests user credentials

The image shows a Fortinet captive portal login page. At the top, the Fortinet logo is displayed in black and red. Below the logo, the text "Authentication Required" is centered in a bold, black font. Underneath this, a message "Please enter your credentials to continue." is centered. There are two input fields: "Username:" followed by a white text box, and "Password:" followed by a white text box. To the right of the password field is a "Continue" button with a light gray background and a thin border.

Typical modifications for this page would be to change the logo and modify some of the text.

You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

There is an exception to this rule. The line "Please enter your credentials to continue" is provided by the `%%QUESTION%%` tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Login failed page**—reports that the entered credentials were incorrect and enables the user to try again.

The image shows a captive portal page for Fortinet. At the top, the Fortinet logo is displayed in black and red. Below the logo, the text "Authentication Failed" is centered in a bold, black font. Underneath this, a message reads "Firewall Authentication failed. Please try again." in a bold, black font. Below the message, there are two input fields: "Username:" followed by a white text box, and "Password:" followed by a white text box. At the bottom right of the form, there is a button labeled "Continue". The entire form is enclosed in a red border.

The Login failed page is similar to the Login page. It even contains the same login form. You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters.

There is an exception to this rule. The line “Firewall authentication failed. Please try again.” is provided by the %%FAILED\_MESSAGE%% tag. You can replace this tag with text of your choice. Except for this item, you should not remove any tags because they may carry information that the FortiGate unit needs.

- **Disclaimer page**—is a statement of the legal responsibilities of the user and the host organization to which the user must agree before proceeding. (WiFi or SSL VPN only)

## Terms and Disclaimer Agreement

You are about to access Internet content that is not under the control of the network access provider. The network access provider is therefore not responsible for any of these sites, their content or their privacy policies. The network access provider and its staff do not endorse nor make any representations about these sites, or any information, software or other products or materials found there, or any results that may be obtained from using them. If you decide to access any Internet content, you do this entirely at your own risk and you are responsible for ensuring that any accessed material does not infringe the laws governing, but not exhaustively covering, copyright, trademarks, pornography, or any other material which is slanderous, defamatory or might cause offence in any other way.

**Do you agree to the above terms?**

Yes, I agree

No, I decline

- **Declined disclaimer page**—is displayed if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

### Changing images in portal messages

You can replace the default Fortinet logo with your organization's logo. First, import the logo file into the FortiGate unit and then modify the Login page code to reference your file.

#### To import a logo file:

1. Go to **System > Replacement Messages** and select **Manage Images**.
2. Select **Create New**.
3. Enter a **Name** for the logo and select the appropriate **Content Type**.  
The file must not exceed 24 Kilo bytes.
4. Select **Browse**, find your logo file and then select **Open**.
5. Select **OK**.

#### To specify the new logo in the replacement message:

1. Go to **Network > Interfaces** and edit the interface.  
The **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
  - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
  - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. In the HTML message text, find the %%IMAGE tag.  
By default it specifies the Fortinet logo: %%IMAGE:logo\_fw\_auth%%
4. Change the image name to the one you provided for your logo.  
The tag should now read, for example, %%IMAGE:mylogo%%
5. Select **Save**.
6. Select **OK**.

## Modifying text in portal messages

Generally, you can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters. You should not remove any tags because they may carry information that the FortiGate unit needs. See the preceding section for any exceptions to this rule for particular pages.

### To modify portal page text

1. Go to **Network > Interfaces** and edit the interface.  
The SSID **Security Mode** must be **Captive Portal**.
2. Select the portal message to edit.
  - In SSL VPN or WiFi interfaces, in **Customize Portal Messages** click the link to the portal messages that you want to edit.
  - In other interfaces, make sure that **Customize Portal Messages** is selected, select the adjacent **Edit** icon, then select the message that you want to edit.
3. Edit the HTML message text, then select **Save**.
4. Select **OK**.

## Configuring disclaimer page for ethernet interface captive portals

While you can customize a disclaimer page for captive portals that connect via WiFi, the same can be done for wired connections. However, this can only be configured on the CLI Console, and only without configuring user groups.

When configuring a captive portal through the CLI, you may set `security-groups` to a specific user group. The result of this configuration will show an authentication form to users who wish to log in to the captive portal—**not** a disclaimer page. If you do not set any `security-groups` in your configuration, an "Allow all" status will be in effect, and the disclaimer page will be displayed for users.

The example CLI configuration below shows setting up a captive portal interface without setting security-groups, resulting in a disclaimer page for users:

```
config system interface
  edit "port1"
    set vdom "root"
    set ip 172.16.101.1 255.255.255.0
    set allowaccess ping https ssh snmp http
    set type physical
    set explicit-web-proxy enable
    set alias "LAN"
    set security-mode captive-portal
    set snmp-index 1
  next
end
```

## Certificate-based authentication

This section provides an overview of how the FortiGate unit verifies the identities of administrators, SSL VPN users, or IPsec VPN peers using X.509 security certificates.

The following topics are included in this section:

- [What is a security certificate?](#)
- [Certificates overview](#)
- [Managing X.509 certificates](#)
- [Configuring certificate-based authentication](#)
- [Support for per-VDOM certificates](#)
- [Certificate-based authentication](#)
- [Example — Generate and Import CA certificate with private key pair on OpenSSL](#)
- [Example — Generate an SSL certificate in OpenSSL](#)

### What is a security certificate?

A security certificate is a small text file that is part of a third-party generated public key infrastructure (PKI) to help guarantee the identity of both the user logging on and the web site they where they are logging in.

A certificate includes identifying information such as the company and location information for the web site, as well as the third-party company name, the expiry date of the certificate, and the public key.

FortiGate units use X.509 certificates to authenticate single sign-on (SSO) for users. The X.509 standard has been in use since before 2000, but has gained popularity with the Internet's increased popularity. X.509 v3 is defined in RFC 5280 and specifies standard formats for public key certificates, certificate revocation lists, and a certification path validation algorithm. The unused earlier X.509 version 1 was defined in RFC 1422.

The main difference between X.509 and PGP certificates is that where in PGP anyone can sign a certificate, for X.509 only a trusted authority can sign certificates. This limits the source of certificates to well known and trustworthy sources. Where PGP is well suited for one-to-one communications, the X.509 infrastructure is intended to be used in many different situations including one-to-many communications. Some common filename extensions for X.509 certificates are listed below.

### Common certificate filename extensions

Filetype	Format name	Description
.pem	Privacy Enhanced Mail (PEM)	Base64 encoded DER certificate, that uses: "-----BEGIN CERTIFICATE-----" and "-----END CERTIFICATE-----"
.cer .crt .der	Security CERTificate	Usually binary DER form, but Base64-encoded certificates are common too.
.p7b .p7c		Structure without data, just certificates or CRLs.  PKCS#7 is a standard for signing or encrypting (officially called "enveloping") data.
.p12	PKCS#12	May contain certificate(s) (public) and private keys (password protected).
.pfx	personal information exchange (PFX)	Older format. Came before PKCS#12. Usually today data is in PKCS#12 format.

## Certificates overview

Certificates play a major role in authentication of clients connecting to network services via HTTPS, both for administrators and SSL VPN users. Certificate authentication is optional for IPsec VPN peers.

This section includes:

- [Certificates and protocols](#)
- [IPsec VPNs and certificates](#)
- [Certificate types on the FortiGate unit](#)

Public CA certificates found on the FortiGate are provided through firmware upgrades and installations.

## Certificates and protocols

There are a number of protocols that are commonly used with certificates including SSL and HTTPS, and other certificate-related protocols.

### SSL and HTTPS

The secure HTTP (HTTPS) protocol uses SSL. Certificates are an integral part of SSL. When a web browser connects to the FortiGate unit via HTTPS, a certificate is used to verify the FortiGate unit's identity to the client. Optionally, the FortiGate unit can require the client to authenticate itself in return.

By default, the FortiGate unit uses a self-signed security certificate to authenticate itself to HTTPS clients. When the certificate is offered, the client browser displays two security messages.

- The first message prompts users to accept and optionally install the FortiGate unit's self-signed security certificate. If the user does not accept the certificate, the FortiGate unit refuses the connection. When the user accepts the certificate, the FortiGate login page is displayed, and the credentials entered by the user are encrypted before they are sent to the FortiGate unit. If the user chooses to install the certificate, the prompt is not displayed again.
- Just before the FortiGate login page is displayed, a second message informs users that the FortiGate certificate distinguished name differs from the original request. This message is displayed because the FortiGate unit redirects the connection (away from the distinguished name recorded in the self-signed certificate) and can be ignored.

Optionally, you can install an X.509 server certificate issued by a certificate authority (CA) on the FortiGate unit. You can then configure the FortiGate unit to identify itself using the server certificate instead of the self-signed certificate.

For more information, see the FortiOS Handbook SSL VPN guide.

After successful certificate authentication, communication between the client browser and the FortiGate unit is encrypted using SSL over the HTTPS link.

### Certificate-related protocols

There are multiple protocols that are required for handling certificates. These include the Online Certificate Status Protocol (OCSP), Secure Certificate Enrollment Protocol (SCEP), and Server-based Certificate Validation Protocol (SCVP).

#### Online Certificate Status Protocol

Online Certificate Status Protocol (OCSP) allows the verification of X.509 certificate expiration dates. This is important to prevent hackers from changing the expiry date on an old certificate to a future date.

Normally certificate revocation lists (CRLs) are used, but OCSP is an alternate method available. However a CRL is a public list, and some companies may want to avoid the public exposure of their certificate structure even if it is only invalid certificates.

The OCSP check on the certificate's revocation status is typically carried out over HTTP with a request-response format. The authority responding can reply with a status of good, revoked, or unknown for the certificate in question.

#### Secure Certificate Enrollment Protocol

Secure Certificate Enrollment Protocol (SCEP) is an automated method of signing up for certificates. Typically this involves generating a request you send directly to the SCEP service, instead of generating a file request that may or may not be signed locally.

#### Server-based Certificate Validation Protocol

Server-based Certificate Validation Protocol (SCVP) is used to trace a certificate back to a valid root level certificate. This ensures that each step along the path is valid and trustworthy.

### IPsec VPNs and certificates

Certificate authentication is a more secure alternative to preshared key (shared secret) authentication for IPsec VPN peers. Unlike administrators or SSL VPN users, IPsec peers use HTTP to connect to the VPN gateway configured on the FortiGate unit. The VPN gateway configuration can require certificate authentication before it

permits an IPsec tunnel to be established. See [Authenticating IPsec VPN users with security certificates on page 484](#).

## Certificate types on the FortiGate unit

There are different types of certificates available that vary depending on their intended use. FortiOS supports local, remote, CA, and CRL certificates.

### Local certificates

Local certificates are issued for a specific server, or web site. Generally they are very specific, and often for an internal enterprise network. For example a personal web site for John Smith at [www.example.com](http://www.example.com) (such as <http://www.example.com/home/jsmith>) would have its own local certificate.

These can optionally be just the certificate file, or also include a private key file and PEM passphrase for added security.

For information about generating a certificate request, see [Generating a certificate signing request on page 474](#). For information about installing a local certificate, see [Obtaining and installing a signed server certificate from an external CA on page 476](#).

### Remote certificates

Remote certificates are public certificates without a private key. For dynamic certificate revocation, you need to use an Online Certificate Status Protocol (OCSP) server. The OCSP is configured in the CLI only. Installed Remote (OCSP) certificates are displayed in the Remote Certificates list. You can select **Import** to install a certificate from the management PC.

### CA root certificates

CA root certificates are similar to local certificates, however they apply to a broader range of addresses or to whole company; they are one step higher up in the organizational chain. Using the local certificate example, a CA root certificate would be issued for all of [www.example.com](http://www.example.com) instead of just the smaller single web page.

### Certificate revocation list

Certificate revocation list (CRL) is a list of certificates that have been revoked and are no longer usable. This list includes certificates that have expired, been stolen, or otherwise compromised. If your certificate is on this list, it will not be accepted. CRLs are maintained by the CA that issues the certificates and includes the date and time when the next CRL will be issued as well as a sequence number to help ensure you have the most current version of the CRL.

### Certificate signing

The trust in a certificate comes from the authority that signs it. For example if VeriSign signs your CA root certificate, it is trusted by everyone. While these certificates are universally accepted, it is cumbersome and expensive to have all certificates on a corporate network signed with this level of trust.

With self-signed certificates nobody, except the other end of your communication, knows who you are and therefore they do not trust you as an authority. However this level is useful for encryption between two points — neither point may care about who signed the certificate, just that it allows both points to communicate. This is very useful for internal networks and communications.

A general rule is that CA signed certificates are accepted and sometimes required, but it is easier to self-sign certificates when you are able.

For more on the methods of certificate signing see [Generating a certificate signing request on page 474](#).

## BIOS certificate compatibility

FortiOS supports backwards compatibility between BIOS version 4 and BIOS version 3.

### BIOS V4 certificates:

- Fortinet\_CA
- Fortinet\_Sub\_CA
- Fortinet\_Factory

### BIOS V3 certificates:

- Fortinet\_CA\_Backup
- Fortinet\_Factory\_Backup

When FortiOS connects to FortiGuard, FortiCloud, FortiManager, FortiAnalyzer, FortiSandbox as a client, the BIOS certificate **Fortinet\_Factory** will be the default client certificate. When the server returns its certificate (chain) back, FortiOS looks up the issuer of the server certificate and either keeps client certificate as is or switches to the BIOS certificate **Fortinet\_Factory\_Backup**. This process occurs in one handshake.

When FortiOS connects to FortiCare, the BIOS certificate **Fortinet\_Factory** is the only client certificate and Server Name Indication (SNI) is set. There is no switchover of certificate during SSL handshake.

When FortiOS acts as a server when connected by FortiExtender, FortiSwitch, FortiAP, etc., **Fortinet\_Factory** is the default server certificate. FortiOS detects SNI in client hello, and if no SNI is found or if the CN in SNI is different from the CN of **Fortinet\_CA**, it switches to use the **Fortinet\_Factory\_Backup**.

## Managing X.509 certificates

Managing security certificates is required due to the number of steps involved in both having a certificate request signed, and then distributing the correct files for use.

You use the FortiGate unit or CA software such as OpenSSL to generate a certificate request. That request is a text file that you send to the CA for verification, or alternately you use CA software to self-validate. Once validated, the certificate file is generated and must be imported to the FortiGate unit before it can be used. These steps are explained in more detail later in this section.

This section provides procedures for generating certificate requests, installing signed server certificates, and importing CA root certificates and CRLs to the FortiGate unit.

For information about how to install root certificates, CRLs, and personal or group certificates on a remote client browser, refer to your browser's documentation.

As a requirement of Network Device Collaborative Protection Profile (NDcPP), FortiOS supports and handles the use of wildcards for the following certificate reference parameters:

- Subject Alternative Name (SAN)
  - Common Name (CN)
-

This section includes:

- [Generating a certificate signing request](#)
- [Generating certificates with CA software](#)
- [Obtaining and installing a signed server certificate from an external CA](#)
- [Installing a CA root certificate and CRL to authenticate remote clients](#)
- [ExtendedKeyUsage for x.509 certificates](#)

## Generating a certificate signing request

Whether you create certificates locally with a software application or obtain them from an external certificate service, you will need to generate a certificate signing request (CSR).

When you generate a CSR, a private and public key pair is created for the FortiGate unit. The generated request includes the public key of the FortiGate unit and information such as the FortiGate unit's public static IP address, domain name, or email address. The FortiGate unit's private key remains confidential on the FortiGate unit.

After you submit the request to a CA, the CA will verify the information and register the contact information on a digital certificate that contains a serial number, an expiration date, and the public key of the CA. The CA will then sign the certificate, and you install the certificate on the FortiGate unit.

The Certificate Request Standard is a public key cryptography standard (PKCS) published by RSA, specifically PKCS10 which defines the format for CSRs. This is defined in RFC 2986.

### To generate a certificate request in FortiOS - web-based manager:

1. Go to **System > Certificates**.
2. Select **Generate**.
3. In the **Certificate Name** field, enter a unique meaningful name for the certificate request. Typically, this would be the hostname or serial number of the FortiGate unit or the domain of the FortiGate unit such as example.com.

Do not include spaces in the certificate name. This will ensure compatibility of a signed certificate as a PKCS12 file to be exported later on if required.

Prior to FortiOS 5.4, passwords for local certificates that were generated via either SCEP or CLI could not have their passwords reset. Passwords can be set in the CLI using the following command:

```
config vpn certificate local
edit <name>
set password <password>
next
end
```

4. Enter values in the **Subject Information** area to identify the FortiGate unit:
  - If the FortiGate unit has a static IP address, select **Host IP** and enter the public IP address of the FortiGate unit. If the FortiGate unit does not have a public IP address, use an email address (or fully qualified domain name (FQDN) if available) instead.

- If the FortiGate unit has a dynamic IP address and subscribes to a dynamic DNS service, use a FQDN if available to identify the FortiGate unit. If you select **Domain Name**, enter the FQDN of the FortiGate unit. Do not include the protocol specification (http://) or any port number or path names.

If a domain name is not available and the FortiGate unit subscribes to a dynamic DNS service, an “unable to verify certificate” type message may be displayed in the user’s browser whenever the public IP address of the FortiGate unit changes.

- If you select **E-Mail**, enter the email address of the owner of the FortiGate unit.
5. Enter values in the **Optional Information** area to further identify the FortiGate unit.

<b>Organization Unit</b>	Name of your department. You can enter a series of OUs up to a maximum of 5. To add or remove an OU, use the plus (+) or minus (-) icon.
<b>Organization</b>	Legal name of your company or organization.
<b>Locality (City)</b>	Name of the city or town where the FortiGate unit is installed.
<b>State/Province</b>	Name of the state or province where the FortiGate unit is installed.
<b>Country</b>	Select the country where the FortiGate unit is installed.
<b>e-mail</b>	Contact email address.
<b>Subject Alternative Name</b>	<p>Optionally, enter one or more alternative names for which the certificate is also valid. Separate names with a comma. A name can be:</p> <ul style="list-style-type: none"> <li>• e-mail address</li> <li>• IP address</li> <li>• URI</li> <li>• DNS name (alternatives to the Common Name)</li> <li>• directory name (alternatives to the Distinguished Name)</li> </ul> <p>You must precede the name with the name type. Examples:</p> <p>IP:1.1.1.1  email:test@fortinet.com  email:my@other.address  URI:http://my.url.here/</p>
<b>Password for private key</b>	Option to export local certificate and its private key in password protected p12.

6. From the **Key Type** list, select **RSA** or **Elliptic Curve**.
7. From the **Key Size** list, select **1024 Bit**, **1536 Bit**, **2048 Bit**, **4096 Bit** or **secp256r1**, **secp384r1**, **secp521r1** respectively. Larger keys are slower to generate but more secure.
8. In **Enrollment Method**, you have two methods to choose from. Select **File Based** to generate the certificate request, or **Online SCEP** to obtain a signed SCEP-based certificate automatically over the network. For the SCEP method, enter the URL of the SCEP server from which to retrieve the CA certificate, and the CA server challenge password.
9. Select **OK**.

10. The request is generated and displayed in the **Local Certificates** list with a status of `PENDING`.
  11. Select the **Download** button to download the request to the management computer.
  12. In the **File Download** dialog box, select **Save** and save the Certificate Signing Request on the local file system of the management computer.
  13. Name the file and save it on the local file system of the management computer.
- The certificate request is ready for the certificate authority to be signed.

## Generating certificates with CA software

CA software allows you to generate unmanaged certificates and CA certificates for managing other certificates locally without using an external CA service. Examples of CA software include `ssl-ca` from OpenSSL (available for Linux, Windows, and Mac) or `gensslcert` from SuSE, MS Windows Server 2000 and 2003 come with a CA as part of their certificate services, and in MS Windows 2008 CA software can be installed as part of the Active Directory installation. See [Example — Generate and Import CA certificate with private key pair on OpenSSL on page 487](#).

The general steps for generating certificates with CA software are

1. Install the CA software as a stand-alone root CA.
2. Provide identifying information for your self-administered CA.

While following these steps, the methods vary slightly when generating server certificates, CA certificates, and PKI certificates.

### Server certificate

1. Generate a Certificate Signing Request (CSR) on the FortiGate unit.
2. Copy the CSR base-64 encoded text (PKCS10 or PKCS7) into the CA software and generate the certificate. PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.
3. Export the certificate as a X.509 DER encoded binary file with `.CER` extension
4. Upload the certificate file to the FortiGate unit Local Certificates page (type is Certificate).

### CA certificate

1. Retrieve the CA Certificate from the CA software as a DER encoded file.
2. Import the CA certificate file to the FortiGate unit at **System > Certificates** and select **Import > Certificates**.

### PKI certificate

1. Generate a Certificate Signing Request (CSR) on the FortiGate unit.
2. Copy the CSR base-64 encoded text (PKCS#10 or PKCS#7) into the CA software and generate the certificate. PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.
3. Export the certificate as a X.509 DER encoded binary file with `.CER` extension.
4. Install the certificate in the user's web browser or IPsec VPN client as needed.

## Obtaining and installing a signed server certificate from an external CA

To obtain a signed server certificate for a FortiGate unit, you must send a request to a CA that provides digital certificates that adhere to the X.509 standard. The FortiGate unit provides a way for you to generate the request.

**To submit the certificate signing request (file-based enrollment):**

1. Using the web browser on the management computer, browse to the CA web site.
2. Follow the CA instructions for a base-64 encoded PKCS#10 certificate request and upload your certificate request.
3. Follow the CA instructions to download their root certificate and CRL.  
When you receive the signed server certificate from the CA, install the certificate on the FortiGate unit.

**To install or import the signed server certificate - web-based manager**

1. On the FortiGate unit, go to **System > Certificates** and select **Import > Local Certificates**.
2. From **Type**, select **Local Certificate**.
3. Select **Browse**, browse to the location on the management computer where the certificate was saved, select the certificate, and then select **Open**.
4. Select **OK**, and then select **Return**.

**Installing a CA root certificate and CRL to authenticate remote clients**

When you apply for a signed personal or group certificate to install on remote clients, you can obtain the corresponding root certificate and CRL from the issuing CA. When you receive the signed personal or group certificate, install the signed certificate on the remote client(s) according to the browser documentation. Install the corresponding root certificate (and CRL) from the issuing CA on the FortiGate unit according to the procedures given below.

**To install a CA root certificate**

1. After you download the root certificate of the CA, save the certificate on the management computer. Or, you can use online SCEP to retrieve the certificate.
2. On the FortiGate unit, go to **System > Certificates** and select **Import > CA Certificates**.
3. Do one of the following:
  - To import using SCEP, select **SCEP**. Enter the URL of the SCEP server from which to retrieve the CA certificate. Optionally, enter identifying information of the CA, such as the filename.
  - To import from a file, select **Local PC**, then select **Browse** and find the location on the management computer where the certificate has been saved. Select the certificate, and then select **Open**.
5. Select **OK**, and then select **Return**.

The system assigns a unique name to each CA certificate. The names are numbered consecutively (CA\_Cert\_1, CA\_Cert\_2, CA\_Cert\_3, and so on).

**To import a certificate revocation list**

A Certificate Revocation List (CRL) is a list of the CA certificate subscribers paired with certificate status information. The list contains the revoked certificates and the reason(s) for revocation. It also records the certificate issue dates and the CAs that issued them.

When configured to support SSL VPNs, the FortiGate unit uses the CRL to ensure that the certificates belonging to the CA and remote peers or clients are valid. The CRL has an “effective date” and a “next update” date. The interval is typically 7 days (for Microsoft CA). FortiOS will update the CRL automatically. Also, there is a CLI command to specify an “update-interval” in seconds. Recommendation should be 24 hours (86400 seconds) but depends on company security policy.

1. After you download the CRL from the CA web site, save the CRL on the management computer.
2. Go to **System > Certificates** and select **Import > CRL**.
3. Do one of the following:
  - To import using an HTTP server, select **HTTP** and enter the URL of the HTTP server.
  - To import using an LDAP server see this KB [article](#).
  - To import using an SCEP server, select **SCEP** and select the Local Certificate from the list. Enter the URL of the SCEP server from which the CRL can be retrieved.
  - To import from a file, select **Local PC**, then select **Browse** and find the location on the management computer where the CRL has been saved. Select the CRL and then select **Open**.
5. Select **OK**, and then select **Return**.

### To import a PKCS12 certificate from the CLI

The following CLI syntax can be entered to import a local certificate file:

```
execute vpn certificate local import tftp <file name> <tftp ip address> <file type> <Enter
for 'cer'>|<password for 'p12'>
```

For example:

```
execute vpn certificate local import tftp FGTF-extern.p12 10.1.100.253 p12 123456
```

In addition, the following CLI syntax can be entered to update certificate bundles from an FTP or TFTP server:

```
execute vpn certificate ca import bundle <file-name.pkg> <ftp/tftp-server-ip>
```

### ExtendedKeyUsage for x.509 certificates

As per Network Device Collaborative Protection Profile (NDcPP) v1.0 requirements, server certificates used for TLS connections between FortiGate and FortiAnalyzer have the "Server Authentication" and "Client Authentication" extendedKeyUsage fields in FIPS/CC mode.

The following CLI command is available under `log fortianalyzer setting` to allow you to specify the certificate used to communicate with FortiAnalyzer.

#### CLI syntax

```
config log fortianalyzer setting
  set certificate <name>
end
```

## Troubleshooting certificates

There are times when there are problems with certificates — a certificate is seen as expired when its not, or it can't be found. Often the problem is with a third party web site, and not FortiOS. However, some problems can be traced back to FortiOS such as DNS or routing issues.

### Enable and disable SHA1 algorithm in SSH key exchanges

In order to investigate your security and conduct compliance testing, a global option allows you to enable/disable SHA1 algorithm in SSH key exchange. Note that, the algorithm is enabled by default.

## Syntax

```
config system global
    set ssh-key-shal {enable | disable}
end
```

## Certificate is reported as expired when it is not

Certificates often are issued for a set period of time such as a day or a month, depending on their intended use. This ensures everyone is using up-to-date certificates. It is also more difficult for hackers to steal and use old certificates.

Reasons a certificate may be reported as expired include:

- It really has expired based on the “best before” date in the certificate
- The FortiGate unit clock is not properly set. If the FortiGate clock is fast, it will see a certificate as expired before the expiry date is really here.
- The requesting server clock is not properly set. A valid example is if your certificate is 2 hours from expiring, a server more than two time zones away would see the certificate as expired. Otherwise, if the server’s clock is set wrongly it will also have the same effect.
- The certificate was revoked by the issuer before the expiry date. This may happen if the issuer believes a certificate was either stolen or misused. Its possible it is due to reasons on the issuer’s side, such as a system change or such. In either case it is best to contact the certificate issuer to determine what is happening and why.

## A secure connection cannot be completed (Certificate cannot be found)

Everyone who uses a browser has encountered a message such as *This connection is untrusted*. Normally when you try to connect securely to a web site, that web site will present its valid certificate to prove their identity is valid. When the web site’s certificate cannot be verified as valid, the message appears stating *This connection is untrusted* or something similar. If you usually connect to this web site without problems, this error could mean that someone is trying to impersonate or hijack the web site, and best practices dictates you not continue.

Reasons a web site’s certificate cannot be validated include:

- The web site uses an unrecognized self-signed certificate. These are not secure because anyone can sign them. If you accept self-signed certificates you do so at your own risk. Best practices dictate that you must confirm the ID of the web site using some other method before you accept the certificate.
- The certificate is valid for a different domain. A certificate is valid for a specific location, domain, or sub-section of a domain such as one certificate for `support.example.com` that is not valid for `marketing.example.com`. If you encounter this problem, contact the webmaster for the web site to inform them of the problem.
- There is a DNS or routing problem. If the web site’s certificate cannot be verified, it will not be accepted. Generally to be verified, your system checks with the third party certificate signing authority to verify the certificate is valid. If you cannot reach that third party due to some DNS or routing error, the certificate will not be verified.
- Firewall is blocking required ports. Ensure that any firewalls between the requesting computer and the web site allow the secure traffic through the firewall. Otherwise a hole must be opened to allow it through. This includes ports such as 443 (HTTPS) and 22 (SSH).

## Online updates to certificates and CRLs

If you obtained your local or CA certificate using SCEP, you can configure online renewal of the certificate before it expires. Similarly, you can receive online updates to CRLs.

## Local certificates

In the `config vpn certificate local` command, you can specify automatic certificate renewal. The relevant fields are:

<code>scep-url &lt;URL_str&gt;</code>	The URL of the SCEP server. This can be HTTP or HTTPS. The following options appear after you add the <code>&lt;URL_str&gt;</code> .
<code>scep-password &lt;password_str&gt;</code>	The password for the SCEP server.
<code>auto-regenerate-days &lt;days_int&gt;</code>	How many days before expiry the FortiGate unit requests an updated local certificate. The default is 0, no auto-update.
<code>auto-regenerate-days-warning &lt;days_int&gt;</code>	How many days before local certificate expiry the FortiGate generates a warning message. The default is 0, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate local
  edit mycert
    set scep-url http://scep.example.com/scep
    set scep-server-password my_pass_123
    set auto-regenerate-days 3
    set auto-regenerate-days-warning 2
  end
```

## CA certificates

In the `config vpn certificate ca` command, you can specify automatic certificate renewal. The relevant fields are:

Variable	Description
<code>scep-url &lt;URL_str&gt;</code>	The URL of the SCEP server. This can be HTTP or HTTPS.
<code>auto-update-days &lt;days_int&gt;</code>	How many days before expiry the FortiGate unit requests an updated CA certificate. The default is 0, no auto-update.
<code>auto-update-days-warning &lt;days_int&gt;</code>	How many days before CA certificate expiry the FortiGate generates a warning message. The default is 0, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate ca
  edit mycert
    set scep-url http://scep.example.com/scep
    set auto-update-days 3
    set auto-update-days-warning 2
  end
```

## Certificate Revocation Lists

If you obtained your CRL using SCEP, you can configure online updates to the CRL using the `config vpn certificate crl` command. The relevant fields are:

Variable	Description
<code>http-url &lt;http_url&gt;</code>	URL of the server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
<code>scep-cert &lt;scep_certificate&gt;</code>	Local certificate used for SCEP communication for CRL auto-update.
<code>scep-url &lt;scep_url&gt;</code>	URL of the SCEP CA server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
<code>update-interval &lt;seconds&gt;</code>	How frequently, in seconds, the FortiGate unit checks for an updated CRL. Enter 0 to update the CRL only when it expires. Not available for http URLs.
<code>update-vdom &lt;update_vdom&gt;</code>	VDOM used to communicate with remote SCEP server for CRL auto-update.

In this example, an updated CRL is requested only when it expires.

```
config vpn certificate crl
  edit cert_crl
    set http-url http://scep.example.com/scep
    set scep-cert my-scep-cert
    set scep-url http://scep.ca.example.com/scep
    set update-interval 0
    set update-vdom root
  end
```

## Backing up and restoring local certificates

The FortiGate unit provides a way to export and import a server certificate and the FortiGate unit's personal key through the CLI. If required (to restore the FortiGate unit configuration), you can import the exported file through the **System > Certificates** page of the web-based manager.

As an alternative, you can back up and restore the entire FortiGate configuration through the **System Information** widget on the Dashboard of the web-based manager. Look for **[Backup]** and **[Restore]** in the **System Configuration** row. The backup file is created in a FortiGate-proprietary format.

### To export a server certificate and private key - CLI:

This procedure exports a server (local) certificate and private key together as a password protected PKCS12 file. The export file is created through a customer-supplied TFTP server. Ensure that your TFTP server is running and accessible to the FortiGate unit before you enter the command.

1. Connect to the FortiGate unit through the CLI.
2. Type the following command:

```
execute vpn certificate local export tftp <cert_name> <exp_filename> <tftp_ip>
<password>
```

where:

- <cert\_name> is the name of the server certificate; typing ? displays a list of installed server certificates.
  - <exp\_filename> is a name for the output file.
  - <tftp\_ip> is the IP address assigned to the TFTP server host interface.
3. Move the output file from the TFTP server location to the management computer for future reference.

### To import a server certificate and private key - web-based manager:

1. Go to **System > Certificates** and select **Import**.
2. In **Type**, select **PKCS12 Certificate**.
3. Select **Browse**. Browse to the location on the management computer where the exported file has been saved, select the file, and then select **Open**.
4. In the **Password** field, type the password needed to upload the exported file.
5. Select **OK**, and then select **Return**.

### To import a server certificate and private key - CLI:

1. Connect to the FortiGate unit through the CLI.
2. Type the following command:

```
execute vpn certificate local import tftp <file_name> <tftp_ip_address> <file_type> <Enter>
for 'cer'>|<password for 'p12'>
```

For example:

```
execute vpn certificate local import tftp FGTF-extern.p12 10.1.100.253 p12 123456
```

### To import separate server certificate and private key files - web-based manager

Use the following procedure to import a server certificate and the associated private key file when the server certificate request and private key were not generated by the FortiGate unit. The two files to import must be available on the management computer.

1. Go to **System > Certificates** and select **Import**.
2. In **Type**, select **Certificate**.
3. Select the **Browse** button beside the **Certificate file** field. Browse to the location on the management computer where the certificate file has been saved, select the file, and then select **Open**.
4. Select the **Browse** button beside the **Key file** field. Browse to the location on the management computer where the key file has been saved, select the file, and then select **Open**.
5. If required, in the **Password** field, type the associated password, and then select **OK**.
6. Select **Return**.

## Configuring certificate-based authentication

You can configure certificate-based authentication for FortiGate administrators, SSL VPN users, and IPsec VPN users.

In Microsoft Windows 7, you can use the certificate manager to keep track of all the different certificates on your local computer. To access certificate manager, in Windows 7 press the Windows key, enter “certmgr.msc” at the search prompt, and select the displayed match. Remember that in addition to these system certificates, many applications require you to register certificates with them directly.

To see FortiClient certificates, open the FortiClient Console, and select VPN. The VPN menu has options for My Certificates (local or client) and CA Certificates (root or intermediary certificate authorities). Use Import on those screens to import certificate files from other sources.

## Authenticating administrators with security certificates

You can install a certificate on the management computer to support strong authentication for administrators. When a personal certificate is installed on the management computer, the FortiGate unit processes the certificate after the administrator supplies a username and password.

To enable strong administrative authentication:

- Obtain a signed personal certificate for the administrator from a CA and load the signed personal certificate into the web browser on the management computer according to the browser documentation.
- Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see [Installing a CA root certificate and CRL to authenticate remote clients on page 477](#) ).
- Create a PKI user account for the administrator.
- Add the PKI user account to a firewall user group dedicated to PKI-authenticated administrators.
- In the administrator account configuration, select **PKI** as the account **Type** and select the **User Group** to which the administrator belongs.

## Support exact match for subject and CN fields in peer user

In order to avoid any unintentional admin access by regular users, administrators can specify which way a peer user authenticates.

When searching for a matching certificate, use the commands below to control how to find matches in the certificate subject name (`subject-match`) or the cn attribute (`cn-match`) of the certificate subject name. This match can be any string (`substring`) or an exact match (`value`) of the cn attribute value.

### To determine certificate subject name matches - CLI:

```
config vpn certificate setting
  edit <name>
    set subject-match {substring | value}
    set cn-match {substring | value}
  next
end
```

## Authenticating SSL VPN users with security certificates

While the default self-signed certificates can be used for HTTPS connections, it is preferable to use the X.509 server certificate to avoid the redirection as it can be misinterpreted as possible session hijacking. However, the server certificate method is more complex than self-signed security certificates. Also the warning message is typically displayed for the initial connection, and future connections will not generate these messages.

X.509 certificates can be used to authenticate IPsec VPN peers or clients, or SSL VPN clients. When configured to authenticate a VPN peer or client, the FortiGate unit prompts the VPN peer or client to authenticate itself using

the X.509 certificate. The certificate supplied by the VPN peer or client must be verifiable using the root CA certificate installed on the FortiGate unit in order for a VPN tunnel to be established.

#### To enable certificate authentication for an SSL VPN user group:

1. Install a signed server certificate on the FortiGate unit and install the corresponding root certificate (and CRL) from the issuing CA on the remote peer or client.
2. Obtain a signed group certificate from a CA and load the signed group certificate into the web browser used by each user. Follow the browser documentation to load the certificates.
3. Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see [Installing a CA root certificate and CRL to authenticate remote clients on page 477](#)).
4. Create a PKI user for each SSL VPN user. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
5. Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the SSL VPN users who are authenticated by certificate.
6. Go to **Policy & Objects > IPv4 Policy**.
7. Edit the SSL-VPN security policy.
8. Select the user group created earlier in the **Source User(s)** field.
9. Select **OK**.

#### Authenticating IPsec VPN users with security certificates

To require VPN peers to authenticate by means of a certificate, the FortiGate unit must offer a certificate to authenticate itself to the peer.

#### To enable the FortiGate unit to authenticate itself with a certificate:

1. Install a signed server certificate on the FortiGate unit.  
See [To install or import the signed server certificate - web-based manager on page 477](#).
2. Install the corresponding CA root certificate on the remote peer or client. If the remote peer is a FortiGate unit, see [To install a CA root certificate on page 477](#).
3. Install the certificate revocation list (CRL) from the issuing CA on the remote peer or client. If the remote peer is a FortiGate unit, see [To import a certificate revocation list on page 477](#).
4. In the VPN phase 1 configuration, set **Authentication Method** to **Signature** and from the **Certificate Name** list select the certificate that you installed in Step 1.

To authenticate a VPN peer using a certificate, you must install a signed server certificate on the peer. Then, on the FortiGate unit, the configuration depends on whether there is only one VPN peer or if this is a dialup VPN that can be multiple peers.

#### To configure certificate authentication of a single peer

1. Install the CA root certificate and CRL.
2. Create a PKI user to represent the peer. Specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
3. In the VPN phase 1 **Peer Options**, select **peer certificate** for **Accept Types** field and select the PKI user that you created in the **Peer certificate** field.

**To configure certificate authentication of multiple peers (dialup VPN)**

1. Install the corresponding CA root certificate and CRL.
2. Create a PKI user for each remote VPN peer. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
3. Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the PKI users who will use the IPsec VPN.

In the VPN phase 1 **Peer Options**, select **peer certificate group** for **Accept Types** field and select the PKI user group that you created in the **Peer certificate group** field.

**Support for per-VDOM certificates**

The CA and local certificate configuration is available per-VDOM. When an admin uploads a certificate to a VDOM, it will only be accessible inside that VDOM. When an admin uploads a certificate to global, it will be accessible to all VDOMs and global.

There are factory default certificates such as Fortinet\_CA\_SSL, Fortinet\_SSL, Fortinet\_Wifi, and Fortinet\_Factory. These certificates are moved to per-VDOM and automatically generated when a new VDOM is created.

The Fortinet\_Firmware certificate has been removed and all the attributes that use Fortinet\_Firmware now use Fortinet\_Factory.

---

**CLI Changes**

Two new attributes `range` and `source` have been added:

`range` can be global or per-VDOM, if the certificate file is imported from global, it is a global certificate. If the certificate file is imported from a VDOM, it is VDOM certificate.

`source` can be either `factory`, `user`, or `fortiguard`:

- `factory`: The factory certificate file with FortiOS version, this includes: Fortinet\_CA\_SSL, Fortinet\_SSL, PositiveSSL\_CA, Fortinet\_Wifi, Fortinet\_Factory.
- `user`: Certificate file imported by the user.
- `fortiguard`: Certificate file imported from FortiGuard.

```
config certificate local
  edit Fortinet_Factory
    set range {global | vdom}
    set source {factory | user | fortiguard}
  end
end
```

**GUI Changes**

Global and new VDOMs have the following factory default certificates:

6. From the **Key Type** list, select **RSA** or **Elliptic Curve**.
7. If RSA is selected, from the **Key Size** list, select **2048 Bit**. If Elliptic Curve is selected, from the **Curve Name** list, select **secp256r1**.
8. In **Enrollment Method**, select **File Based** to generate the certificate request
9. Select **OK**.  
The request is generated and displayed in the **Local Certificates** list with a status of PENDING.
10. Select the **Download** button to download the request to the management computer.
11. In the **File Download** dialog box, select **Save** and save the Certificate Signing Request on the local file system of the management computer.
12. Name the file and save it on the local file system of the management computer.

## Example — Generate and Import CA certificate with private key pair on OpenSSL

This example explains how to generate a certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

### Assumptions

Before starting this procedure, ensure that you have downloaded and installed OpenSSL on Windows. One source is: <http://www.slproweb.com/products/Win32OpenSSL.html>.

### Generating and importing the CA certificate and private key

The two following procedures will generate a CA certificate file and private key file, and then import it to the FortiGate unit as a local certificate.

#### To generate the private key and certificate

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the command:

```
cd c:\OpenSSL-Win32\bin
```

2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet123.

```
openssl genrsa -aes256 -out fgtpcapriv.key 2048
```

This command generates an RSA AES256 2048-bit encryption key.

3. The following command will generate the certificate using the key from the previous step.

```
openssl req -new -x509 -days 3650 -extensions v3_ca -key fgtpcapriv.key -out  
fgtca.crt
```

This step generates an X509 CA certificate good for 10 years that uses the key generated in the previous step. The certificate filename is `fgtca.crt`.

You will be prompted to enter information such as PEM Pass Phrase from the previous step, Country Name, State, Organization Name, Organizational Unit (such as department name), Common Name (the FQDN), and Email Address.

**To import the certificate to the FortiGate unit - web-based manager:**

1. Go to **System > Certificates**.
2. Select **Import > Local Certificate**.
3. Select **Certificate** for **Type**.  
Fields for Certificate file, Key file, and Password are displayed.
4. For **Certificate file**, enter `c:\OpenSSL-Win32\bin\fgtca.crt`.
5. For **Key file**, enter `c:\OpenSSL-Win32\bin\fgtcapriv.key`.
6. For **Password**, enter the PEM Pass Phrase you entered earlier, such as `fortinet123`.
7. Select **OK**.

The Certificate will be added to the list of Local Certificates and be ready for use. It will appear in the list as the filename you uploaded — `fgtca`. You can add comments to this certificate to make it clear where its from and how it is intended to be used. If you download the certificate from FortiOS, it is a .CER file.

It can now be used in [Authenticating IPsec VPN users with security certificates on page 484](#), and [Authenticating SSL VPN users with security certificates on page 483](#).

**Example — Generate an SSL certificate in OpenSSL**

This example explains how to generate a CA signed SSL certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

In this example, you will:

- Generate a CA signed SSL certificate
- Generate a self-signed SSL certificate
- Import the SSL certificate into FortiOS

**Assumptions**

- Before starting this procedure, ensure that you have downloaded and installed OpenSSL on MS Windows. One download source is <http://www.slproweb.com/products/Win32OpenSSL.html>.

**Generating a CA signed SSL certificate**

This procedure assumes that you have already completed [Example — Generate and Import CA certificate with private key pair on OpenSSL on page 487](#) successfully.

**To generate the CA signed SSL certificate:**

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:

```
cd c:\OpenSSL-Win32\bin
```

2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as `fortinet`.

```
openssl genrsa -aes256 -out fgtssl.key 2048
```

This command generates an RSA AES256 2048-bit encryption key.

3. Create a certificate signing request for the SSL certificate. This step requires you to enter the information listed in step 3 of the previous example — [To generate the private key and certificate](#). You can leave the Challenge Password blank.

```
openssl req -new -sha256 -key fgtssl.key -out fgtssl.csr
```

Most Certificate Authorities will ignore the value that is set in the CSR and use whatever value they are set to use in their configuration. This means that the client will likely need to modify their openssl.conf file to use SHA-256 (or another SHA-2 variant).

---

4. Using the CSR from the previous step, you can now create the SSL certificate using the CA certificate that was created in [Example — Generate and Import CA certificate with private key pair on OpenSSL](#).

```
openssl x509 -req -days 365 -in fgtssl.csr -CA fgtca.crt -CAkey fgtpcapriv.key -set_  
serial 01 -out fgtssl.crt
```

This will generate an X.509 certificate good for 365 days signed by the CA certificate fgtca.crt.

## Generating a self-signed SSL certificate

This procedure does not require any existing certificates.

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:

```
cd c:\OpenSSL-Win32\bin
```

2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet.

```
openssl genrsa -aes256 -out fgtssl.key 2048  
openssl req -new -key fgtssl.key -out fgtssl.csr  
openssl x509 -req -days 365 -in fgtssl.csr -signkey fgtssl.key -out fgtssl.crt
```

These commands:

- generate an RSA AES256 2048-bit private key,
- generate an SSL certificate signing request, and
- sign the CSR to generate an SSL .CRT certificate file.

## Import the SSL certificate into FortiOS

### To import the certificate to FortiOS- web-based manager

1. Go to **System > Certificates**.
2. Select **Import > Local Certificate**.
3. Select **Certificate** for **Type**.  
Fields for Certificate file, Key file, and Password are displayed.
4. For **Certificate file**, enter `c:\OpenSSL-Win32\bin\fgtssl.crt`.
5. For **Key file**, enter `c:\OpenSSL-Win32\bin\fgtssl.key`.

6. For **Password**, enter the PEM Pass Phrase you entered, such as fortinet.

7. Select **OK**.

The SSL certificate you just uploaded can be found under **System > Certificates** under the name of the file you uploaded — fgtssl.

**To confirm the certificate is uploaded properly - CLI:**

```
config vpn certificate local
  edit fgtssl
    get
  end
```

The get command will display all the certificate's information. If it is not there or the information is not correct, you will need to remove the corrupted certificate (if it is there) and upload it again from your PC.

**To use the new SSL certificate - CLI**

```
config vpn ssl settings
  set servercert fgtssl
end
```

This assigns the fgtssl certificate as the SSL server certificate. For more information see the FortiOS Handbook SSL VPN guide.

## Single Sign-On using a FortiAuthenticator unit

If you use a FortiAuthenticator unit in your network as a single sign-on agent,

- Users can authenticate through a web portal on the FortiAuthenticator unit.
- Users with FortiClient Endpoint Security installed can be automatically authenticated by the FortiAuthenticator unit through the FortiClient SSO Mobility Agent.

The FortiAuthenticator unit can integrate with external network authentication systems such as RADIUS and LDAP to gather user login information and send it to the FortiGate unit.

### User's view of FortiAuthenticator SSO authentication

There are two different ways users can authenticate through a FortiAuthenticator unit.

#### Users without FortiClient Endpoint Security - SSO widget

To log onto the network, the user accesses the organization's web page with a web browser. Embedded on that page is a simple logon widget, like this:

<b>Login</b>	User not logged in. Click <b>Login</b> to go to the FortiAuthenticator login page.
jsmith <b>Logout</b>	User logged in. Name displayed. <b>Logout</b> button available.

The SSO widget sets a cookie on the user's browser. When the user browses to a page containing the login widget, the FortiAuthenticator unit recognizes the user and updates its database if the user's IP address has changed. The user will not need to re-authenticate until the login timeout expires, which can be up to 30 days.

#### Users with FortiClient Endpoint Security - FortiClient SSO Mobility Agent

The user simply accesses resources and all authentication is performed transparently with no request for credentials. IP address changes, such as those due to WiFi roaming, are automatically sent to the FortiAuthenticator unit. When the user logs off or otherwise disconnects from the network, the FortiAuthenticator unit is aware of this and deauthenticates the user.

The FortiClient SSO Mobility Agent, a feature of FortiClient Endpoint Security v5.0, must be configured to communicate with the appropriate FortiAuthenticator unit. After that, the agent automatically provides user name and IP address information to the FortiAuthenticator unit for transparent authentication.

### Administrator's view of FortiAuthenticator SSO authentication

You can configure either or both of these authentication types on your network.

#### SSO widget

You need to configure the Single Sign-On portal on the FortiAuthenticator unit. Go to **Fortinet SSO Methods > SSO > Portal Services** to do this. Copy the **Embeddable login widget** code for use on your organization's

home page. Identity-based security policies on the FortiGate unit determine which users or groups of users can access which network resources.

### FortiClient SSO Mobility Agent

Your users must be running at least FortiClient Endpoint Security v5.0 to make use of this type of authentication.

On the FortiAuthenticator unit, you need to select **Enable FortiClient SSO Mobility Agent Service**, optionally select **Enable Authentication** and choose a **Secret key**. Go to **Fortinet SSO Methods > SSO > General**. You need to provide your users the FortiAuthenticator IP address and secret key so that they can configure the FortiClient SSO Mobility Agent on their computers. See [Configuring the FortiGate unit on page 493](#).

## Configuring the FortiAuthenticator unit

The FortiAuthenticator unit can poll FortiGate units, Windows Active Directory, RADIUS servers, LDAP servers, and FortiClients for information about user logon activity.

### To configure FortiAuthenticator polling:

1. Go to **Fortinet SSO Methods > SSO > General**.
2. In the **FortiGate** section, leave the Listening port at 8000, unless your network requires you to change this. The FortiGate unit must allow traffic on this port to pass through the firewall. Optionally, you can set the Login Expiry time. This is the length of time users can remain logged in before the system logs them off automatically. The default is 480 minutes (8 hours).
3. Select **Enable Authentication** and enter the **Secret key**. Be sure to use the same secret key when configuring the FSSO Agent on FortiGate units.
4. In the **Fortinet Single Sign-On (FSSO)** section, enter

<b>Enable Windows Active Directory domain controllers</b>	Select for integration with Windows Active Directory.
<b>Enable Radius accounting SSO clients</b>	Select if you want to use a Remote Radius server.
<b>Enable Syslog SSO</b>	Select for integration with Syslog server.
<b>Enable FortiClient SSO Mobility Agent service</b> <b>Enable Authentication</b>	Select both options to enable single sign-on by clients running FortiClient Endpoint Security. Enter the <b>Secret key</b> . Be sure to use the same secret key in the FortiClient Single Sign-On Mobility Agent settings.

5. Select **OK**.

For more information, see the FortiAuthenticator Administration Guide.

## Configuring the FortiGate unit

### Adding a FortiAuthenticator unit as an SSO agent

On the FortiGate unit, you need to add the FortiAuthenticator unit as a Single Sign-On agent that provides user logon information.

**To add a FortiAuthenticator unit as SSO agent:**

1. Go to **User & Device > Single Sign-On** and select **Create New**.
2. In **Type**, select **Fortinet Single-Sign-On Agent**.
3. Enter a **Name** for the FortiAuthenticator unit.
4. In **Primary Agent IP/Name**, enter the IP address of the FortiAuthenticator unit.
5. In **Password**, enter the secret key that you defined for the FortiAuthenticator unit.  
On the FortiAuthenticator unit, you go to **Fortinet SSO Methods > SSO > General** to define the secret key. Select **Enable Authentication**.
6. Select **OK**.

In a few minutes, the FortiGate unit receives a list of user groups from the FortiAuthenticator unit. The entry in the Single Sign-On server list shows a blue caret.

When you open the server, you can see the list of groups. You can use the groups in identity-based security policies.

### Configuring an FSSO user group

You cannot use FortiAuthenticator SSO user groups directly in a security policy. Create an FSSO user group and add FortiAuthenticator SSO user groups to it. FortiGate FSSO user groups are available for selection in identity-based security policies.

**To create an FSSO user group:**

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a **Name** for the group.
3. In **Type**, select **Fortinet Single Sign-On (FSSO)**.
4. Add **Members**.  
The groups available to add as members are SSO groups provided by SSO agents.
5. Select **OK**.

### Configuring security policies

You can create identity-based policies based on FSSO groups as you do for local user groups. For more information about security policies see the Firewall chapter.

## Configuring the FortiClient SSO Mobility Agent

The user's device must have at least FortiClient Endpoint Security v5.0 installed. Only two pieces of information are required to set up the SSO Mobility Agent feature: the FortiAuthenticator unit IP address and the preshared secret.

The user needs to know the FortiAuthenticator IP address and preshared secret to set up the SSO Mobility Agent. Or, you could preconfigure FortiClient.

### To configure FortiClient SSO Mobility Agent:

1. In FortiClient Endpoint Security, go to **File > Settings**.  
You must run the FortiClient application as an administrator to access these settings.
2. Select **Enable single sign-on mobility agent**. Enter the FortiAuthenticator unit IP address, including the listening port number specified on the FortiAuthenticator unit.  
Example: 192.168.0.99:8001. You can omit the port number if it is 8005.
3. Enter the preshared key.
4. Select **OK**.

## Viewing SSO authentication events on the FortiGate unit

User authentication events are logged in the FortiGate event log.

Go to **Log & Report > System Events**.

The screenshot shows the FortiGate web interface for FortiWiFi 60CX-ADSL-A. The left sidebar shows the navigation menu with 'Log & Report' selected. The main content area displays a table of system events. The table has columns: #, Date/Time, Level, User, Action, Message, and Group. The events are listed in descending order of time, showing various users logging on and off the FortiAuthenticator unit.

#	Date/Time	Level	User	Action	Message	Group
1	1 minute ago	notice	KADIMUNDI	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user KADIMUNDI logged on 192.168.1.100"	
2	1 minute ago	notice	aventress	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user aventress logged on 192.168.0.150"	
3	2 minutes ago	notice	KADIMUNDI	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user KADIMUNDI logged on 192.168.1.100"	
4	2 minutes ago	notice	DOMAINADMIN	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user DOMAINADMIN logged on 192.168.1.100"	
5	3 minutes ago	notice	ATANO	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user ATANO logged on 192.168.1.101"	
6	6 minutes ago	notice	DOMAINADMIN	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user DOMAINADMIN logged on 192.168.1.100"	
7	11 minutes ago	notice	DOMAINADMIN	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user DOMAINADMIN logged on 192.168.1.100"	
8	16 minutes ago	notice	DOMAINADMIN	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user DOMAINADMIN logged on 192.168.1.100"	
9	20 minutes ago	notice	DOMAINADMIN	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user DOMAINADMIN logged on 192.168.1.100"	
10	21 minutes ago	notice	DOMAINADMIN	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user DOMAINADMIN logged on 192.168.1.100"	
11	26 minutes ago	notice	DOMAINADMIN	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user DOMAINADMIN logged on 192.168.1.100"	
12	31 minutes ago	notice	DOMAINADMIN	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user DOMAINADMIN logged on 192.168.1.100"	
13	35 minutes ago	notice	DOMAINADMIN	FSSO-logout	FSSO-logout event from FortiAuthenticator_2.0: user DOMAINADMIN logged on 192.168.1.100"	

Below the table, there is a detailed view of the selected event (1 minute ago, Mon Oct 1 17:59:08 2012). It shows the Level as 'notice', Sub Type as 'user', User as 'KADIMUNDI', Action as 'FSSO-logout', Message as 'FSSO-logout event from FortiAuthenticator\_2.0: user KADIMUNDI logged on 192.168.1.100"', Src as '192.168.1.100', and Dst as 'FortiAuthenticator\_2.0'.

## Single Sign-On to Windows AD

The FortiGate unit can authenticate users transparently and allow them network access based on their privileges in Windows AD. This means that users who have logged on to the network are not asked again for their credentials to access network resources through the FortiGate unit, hence the term “Single Sign-On”.

The following topics are included:

- [Introduction to Single Sign-On with Windows AD](#)
- [Configuring Single Sign On to Windows AD](#)
- [FortiOS FSSO log messages](#)
- [Testing FSSO](#)
- [Troubleshooting FSSO](#)

### Introduction to Single Sign-On with Windows AD

Introduced in FortiOS 5.0, Single Sign-On (SSO) support provided by FortiGate polling of domain controllers is simpler than the earlier method that relies on agent software installed on Windows AD network servers. No Fortinet software needs to be installed on the Windows network. The FortiGate unit needs access only to the Windows AD global catalog and event log.

When a Windows AD user logs on at a workstation in a monitored domain, the FortiGate unit

- detects the logon event in the domain controller’s event log and records the workstation name, domain, and user,
- resolves the workstation name to an IP address,
- uses the domain controller’s LDAP server to determine which groups the user belongs to,
- creates one or more log entries on the FortiGate unit for this logon event as appropriate.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. The selection consist of matching the FSSO group or groups the user belongs to with the security policy or policies that match that group. If the user belongs to one of the permitted user groups associated with that policy, the connection is allowed. Otherwise the connection is denied.

### Configuring Single Sign On to Windows AD

On the FortiGate unit, security policies control access to network resources based on user groups. With Fortinet Single Sign On, this is also true but each FortiGate user group is associated with one or more Windows AD user groups. This is how Windows AD user groups get authenticated in the FortiGate security policy.

Fortinet Single Sign On sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate unit.

To configure your FortiGate unit to operate with either a Windows AD or a Novell eDirectory FSSO install, you

- Configure LDAP access to the Windows AD global catalog. See [Configuring LDAP server access on page 496](#).
- Configure the LDAP Server as a Single Sign-On server. See [Configuring the LDAP Server as a Single Sign-On server on page 497](#).

- Add Active Directory user groups to FortiGate FSSO user groups. See [Creating Fortinet Single Sign-On \(FSSO\) user groups on page 498](#).
- Create security policies for FSSO-authenticated groups. See [Creating security policies on page 498](#).
- Optionally, specify a guest protection profile to allow guest access. See [Enabling guest access through FSSO security policies on page 500](#)

## Configuring LDAP server access

The FortiGate unit needs access to the domain controller's LDAP server to retrieve user group information.

The LDAP configuration on the FortiGate unit not only provides access to the LDAP server, it sets up the retrieval of Windows AD user groups for you to select in FSSO. The LDAP Server configuration, found under **User & Device > LDAP Servers**, includes a function to preview the LDAP server's response to your distinguished name query. If you already know the appropriate Distinguished Name (DN) and User DN settings, you may be able to skip some of the following steps.

### To add an LDAP server - web-based manager:

1. Go to **User & Device > LDAP Servers** and select **Create New**.
2. Enter the **Server IP/Name** and **Server Port** (default 389).
3. In the **Common Name Identifier** field, enter **sAMAccountName**. The default common name identifier is **cn**. This is correct for most LDAP servers. However some servers use other identifiers such as **uid**.
4. In the **Distinguished Name** field, enter your organization distinguished name. In this example, Distinguished Name is **dc=techdoc,dc=local**
5. Select **Fetch DN**, this will fetch the Windows AD directory.

Name	LDAP
Server IP/Name	10.10.20.3
Server Port	389
Common Name Identifier	sAMAccountName
Distinguished Name	dc=techdoc,dc=local
Bind Type	
User DN	
Password	
<input type="checkbox"/> Secure Connection	
<b>Test</b>	

**LDAP Distinguished Name Query**

LDAP Tree

- [-] dc=techdoc,dc=local
  - [-] CN=Computers
  - [-] CN=ForeignSecurityPrincipals
  - [-] CN=Managed Service Accounts
  - [-] CN=Program Data
  - [-] CN=System
  - [-] CN=Users
  - [-] OU=Domain Controllers

6. Set **Bind Type** to **Regular**.
7. In the **User DN** field, enter the administrative account name that you created for FSSO. For example, if the account is administrator, enter "administrator@techdoc.local".

8. Enter the administrative account password in the **Password** field.
9. Optionally select **Secure Connection**.
  - In the **Protocol** field, select **LDAPS** or **STARTTLS**.
  - In the **Certificate** field, select the appropriate certificate for authentication.

Note that you need to configure the Windows AD for secure connection accordingly.
10. Select **OK**.
11. Test your configuration by selecting the **Test** button. A successful message confirming the right settings appears.

The screenshot shows a configuration window for LDAP. At the top, a status bar indicates 'Successful'. The configuration fields are as follows:

Name	LDAP
Server IP/Name	10.10.20.3
Server Port	389
Common Name Identifier	sAMAccountName
Distinguished Name	dc=techdoc,dc=local
	<b>Fetch DN</b>
Bind Type	<input type="radio"/> Simple <input type="radio"/> Anonymous <input checked="" type="radio"/> Regular
User DN	administrator@techdoc.local
Password	••••••••
<input type="checkbox"/> Secure Connection	
<b>Test</b>	

#### To configure LDAP for FSSO - CLI example:

```
config user ldap
edit LDAP
set server 10.10.20.3
set cnid sAMAccountName
set dn dc=techdoc,dc=local
set type regular
set username administrator@techdoc.local
set password <your_password>
next
end
```

### Configuring the LDAP Server as a Single Sign-On server

The LDAP server must be added to the FortiGate Single Sign-On configuration.

#### To add the LDAP server as a Single Sign-On server:

1. Go to **User & Device > Single Sign-On** and select **Create New**.
2. Enter

<b>Type</b>	Poll Active Directory Server
<b>Server IP/Name</b>	Server Name or IP address of the Domain Controller
<b>User</b>	A Domain user name
<b>Password</b>	The user's password

<b>LDAP Server</b>	Select the LDAP server you added earlier.
<b>Enable Polling</b>	Select

3. Select **OK**.

## Creating Fortinet Single Sign-On (FSSO) user groups

You cannot use Windows or Novell groups directly in FortiGate security policies. You must create FortiGate user groups of the FSSO type and add Windows or Novell groups to them.

### To create a user group for FSSO authentication - web-based manager:

1. Go to **User & Device > User Groups** and select **Create New**.  
The **New User Group** dialog box opens.
2. In the **Name** box, enter a name for the group, FSSO\_Internet\_users for example.
3. In **Type**, select **Fortinet Single Sign-On (FSSO)**.
4. In **Members**, select the required **FSSO** groups.
5. Select **OK**.

### To create the FSSO\_Internet-users user group - CLI

```
config user group
  edit FSSO_Internet_users
    set group-type fssso-service
    set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
    CN=Sales,cn=users,dc=office,dc=example,dc=com
  end
```

## Default FSSO group

`SSO_Guest_users` is a default user group enabled when FSSO is configured. It allows guest users on the network who do not have an FSSO account to authenticate and have access to network resources. See [Enabling guest access through FSSO security policies on page 500](#).

## Creating security policies

Policies that require FSSO authentication are very similar to other security policies. Using identity-based policies, you can configure access that depends on the FSSO user group. This allows each FSSO user group to have its own level of access to its own group of services

In this situation, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fssso_group`, and the FSSO RADIUS server is `fssso_rad_server`.

**To configure an FSSO authentication security policy - web-based manager:**

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information.

<b>Incoming Interface</b>	port1
<b>Source Address</b>	company_network
<b>Source User(s)</b>	fsso_group
<b>Outgoing Interface</b>	port2
<b>Destination Address</b>	all
<b>Schedule</b>	always
<b>Service</b>	HTTP, HTTPS, FTP, and Telnet
<b>Action</b>	ACCEPT
<b>NAT</b>	ON
<b>UTM Security Profiles</b>	ON for AntiVirus, IPS, Web Filter, and Email Filter, all using default profiles.
<b>Log Allowed Traffic</b>	ON. Select <b>Security Events</b> .

3. Select **OK**.
4. Ensure the FSSO authentication policy is higher in the policy list than more general policies for the same interfaces.

**To create a security policy for FSSO authentication - CLI:**

```
config firewall policy
edit 0
set srcintf port1
set dstintf port2
set srcaddr company_network
set dstaddr all
set action accept
set groups fsso_group
set schedule always
set service HTTP HTTPS FTP TELNET
set nat enable
end
```

Here is an example of how this FSSO authentication policy is used. Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet.

## Enabling guest access through FSSO security policies

You can enable guest users to access FSSO security policies. Guests are users who are unknown to Windows AD and servers that do not logon to a Windows AD domain.

To enable guest access in your FSSO security policy, add an identity-based policy assigned to the built-in user group `SSO_Guest_Users`. Specify the services, schedule and UTM profiles that apply to guest users — typically guests have access to a reduced set of services. See [Creating security policies on page 498](#).

## FortiOS FSSO log messages

There are two types of FortiOS log messages — firewall and event. FSSO related log messages are generated from authentication events. These include user logon and log off events, and NTLM authentication events. These log messages are central to network accounting policies, and can also be useful in troubleshooting issues. For more information on firewall logging, see [Enabling security logging on page 444](#). For more information on logging, see the FortiOS Handbook Logging and Reporting guide.

### Enabling authentication event logging

For the FortiGate unit to log events, that specific type of event must be enabled under logging.

When VDOMs are enabled certain options may not be available, such as CPU and memory usage events. You can enable event logs only when you are logged on to a VDOM; you cannot enable event logs globally.

To ensure you log all the events needed, set the minimum log level to Notification or Information. Firewall logging requires Notification as a minimum. The closer to Debug level, the more information will be logged.

#### To enable event logging:

1. Go to **Log & Report > Log Settings**.
2. Under **Log Settings**, set **Event Logging** to **Customize** and select

<b>System activity event</b>	All system-related events, such as ping server failure and gateway status.
<b>User activity event</b>	All administration events, such as user logins, resets, and configuration updates.

3. Select **Apply**.

#### List of FSSO related log messages

Message ID	Severity	Description
<b>43008</b>	Notification	Authentication was successful
<b>43009</b>	Notification	Authentication session failed
<b>43010</b>	Warning	Authentication locked out
<b>43011</b>	Notification	Authentication timed out
<b>43012</b>	Notification	FSSO authentication was successful

Message ID	Severity	Description
43013	Notification	FSSO authentication failed
43014	Notification	FSSO user logged on
43015	Notification	FSSO user logged off
43016	Notification	NTLM authentication was successful
43017	Notification	NTLM authentication failed

For more information on logging, see the FortiOS Handbook Logging and Reporting guide.

### Extra filter options for security events

Logon events are detected by the FSSO CA by monitoring the Security Event logs. Additional logon event filters, such as ServiceName and ServiceID, have been implemented so as to avoid instances of conflicting security events, where existing user information could be overwritten.

## Testing FSSO

Once FSSO is configured, you can easily test to ensure your configuration is working as expected. For additional FSSO testing, see [Troubleshooting FSSO on page 501](#).

1. Logon to one of the stations on the FSSO domain, and access an Internet resource.
2. Connect to the CLI of the FortiGate unit, and if possible log the output.
3. Enter the following command: `diagnose debug authd fsso list`
4. Check the output. If FSSO is functioning properly you will see something similar to the following:

```
----FSSO logons----
IP: 192.168.1.230 User: ADMINISTRATOR Groups: VLAD-AD/DOMAIN USERS
IP: 192.168.1.240 User: ADMINISTRATOR Groups: VLAD-AD/DOMAIN USERS
Total number of users logged on: 2
----end of FSSO logons----
```

The exact information will vary based on your installation.

5. Check the FortiGate event log, for FSSO-auth action or other FSSO related events with FSSO information in the message field.
6. To check server connectivity, run the following commands from the CLI:

```
FGT# diagnose debug enable
FGT# diagnose debug authd fsso server-status
FGT# Server Name Connection Status
-----
SBS-2003 connected
```

## Troubleshooting FSSO

When installing, configuring, and working with FSSO some problems are quite common. A selection of these problems follows including explanations and solutions.

Some common Windows AD problems include:

- General troubleshooting tips for FSSO
- Users on a particular computer (IP address) can not access the network
- Guest users do not have access to network

## General troubleshooting tips for FSSO

The following tips are useful in many FSSO troubleshooting situations.

- Ensure all firewalls are allowing the FSSO required ports through.  
FSSO has a number of required ports that must be allowed through all firewalls or connections will fail. These include: ports 139, 389 (LDAP), 445, 636 (LDAP).
- Ensure there is at least 64kbps bandwidth between the FortiGate unit and domain controllers. If there is insufficient bandwidth, some FSSO information might not reach the FortiGate unit. The best solution is to configure traffic shaping between the FortiGate unit and the domain controllers to ensure that the minimum bandwidth is always available.

## Users on a particular computer (IP address) can not access the network

Windows AD Domain Controller agent gets the username and workstation where the logon attempt is coming from. If there are two computers with the same IP address and the same user trying to logon, it is possible for the authentication system to become confused and believe that the user on computer\_1 is actually trying to access computer\_2.

Windows AD does not track when a user logs out. It is possible that a user logs out on one computer, and immediately logs onto a second computer while the system still believes the user is logged on the original computer. While this is allowed, information that is intended for the session on one computer may mistakenly end up going to the other computer instead. The result would look similar to a hijacked session.

## Solutions

- Ensure each computer has separate IP addresses.
- Encourage users to logout on one machine before logging onto another machine.
- If multiple users have the same username, change the usernames to be unique.
- Shorten timeout timer to flush inactive sessions after a shorter time.

## Guest users do not have access to network

A group of guest users was created, but they don't have access.

## Solution

The group of the guest users was not included in a policy, so they do not fall under the guest account. To give them access, associate their group with a security policy.

Additionally, there is a default group called `SSO_Guest_Users`. Ensure that group is part of an identity-based security policy to allow traffic.

## Agent-based FSSO

FortiOS can provide single sign-on capabilities to Windows AD, Citrix, Novell eDirectory, or, as of FortiOS 5.4, Microsoft Exchange users with the help of agent software installed on these networks. The agent software sends information about user logons to the FortiGate unit. With user information such as IP address and user group memberships from the network, FortiGate security policies can allow authenticated network access to users who belong to the appropriate user groups without requesting their credentials again.

For Windows AD networks, FortiGate units can provide SSO capability without agent software by directly polling the Windows AD domain controllers. For information about this type of SSO, see [Single Sign-On to Windows AD on page 495](#).

The following topics are included:

- [Introduction to agent-based FSSO](#)
- [FSSO NTLM authentication support](#)
- [Agent installation](#)
- [Configuring the FSSO Collector agent for Windows AD](#)
- [Configuring the FSSO TS agent for Citrix](#)
- [Configuring FSSO with Novell networks](#)
- [Configuring FSSO Advanced Settings](#)
- [Configuring FSSO on FortiGate units](#)
- [FortiOS FSSO log messages](#)
- [Testing FSSO](#)
- [Troubleshooting FSSO](#)

### Introduction to agent-based FSSO

Fortinet Single Sign-On (FSSO), through agents installed on the network, monitors user logons and passes that information to the FortiGate unit. When a user logs on at a workstation in a monitored domain, FSSO

- detects the logon event and records the workstation name, domain, and user,
- resolves the workstation name to an IP address,
- determines which user groups the user belongs to,
- sends the user logon information, including IP address and groups list, to the FortiGate unit
- creates one or more log entries on the FortiGate unit for this logon event as appropriate.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups associated with that policy, the connection is allowed. Otherwise the connection is denied.

FSSO can also provide NTLM authentication service for requests coming from FortiGate. SSO is very convenient for users, but may not be supported across all platforms. NTLM is not as convenient, but it enjoys wider support. See [FSSO NTLM authentication support on page 509](#).

---

## Introduction to FSSO agents

There are several different FSSO agents that can be used in an FSSO implementation:

- Domain Controller (DC) agent
- eDirectory agent
- Citrix/Terminal Server (TS) agent
- Collector (CA) agent

Consult the latest FortiOS and FSSO Release Notes for operating system compatibility information.

### Domain Controller (DC) agent

The Domain Controller (DC) agent must be installed on every domain controller if you will use DC Agent mode, but is not required if you use Polling mode. See [FSSO for Windows AD on page 505](#).

### eDirectory agent

The eDirectory agent is installed on a Novell network to monitor user logons and send the required information to the FortiGate unit. It functions much like the Collector agent on a Windows AD domain controller. The agent can obtain information from the Novell eDirectory using either the Novell API or LDAP.

### Citrix/Terminal Server (TS) agent

The Citrix/Terminal Server (TS) agent is installed on a Citrix terminal server to monitor user logons in real time. It functions much like the DC Agent on a Windows AD domain controller.

### Collector (CA) agent

This agent is installed as a service on a server in the Windows AD network to monitor user logons and send the required information to the FortiGate unit. The Collector agent can collect information from

- Domain Controller agent (Windows AD)
- TS agent (Citrix Terminal Server)

In a Windows AD network, the Collector agent can optionally obtain logon information by polling the AD domain controllers. In this case, DC agents are not needed.

The Collector can obtain user group information from the DC agent or optionally, a FortiGate unit can obtain group information directly from AD using Lightweight Directory Access Protocol (LDAP).

On a Windows AD network, the FSSO software can also serve NT LAN Manager (NTLM) requests coming from client browsers (forwarded by the FortiGate unit) with only one or more Collector agents installed. See [FSSO NTLM authentication support on page 509](#).

The CA is responsible for DNS lookups, group verification, workstation checks, and as mentioned FortiGate updates of logon records. The FSSO Collector Agent sends Domain Local Security Group and Global Security Group information to FortiGate units. The CA communicates with the FortiGate over TCP port 8000 and it listens on UDP port 8002 for updates from the DC agents.

The FortiGate unit can have up to five CAs configured for redundancy. If the first on the list is unreachable, the next is attempted, and so on down the list until one is contacted. See [Configuring FSSO on FortiGate units on page 537](#).

All DC agents must point to the correct Collector agent port number and IP address on domains with multiple DCs.

A FortiAuthenticator unit can act much like a Collector agent, collecting Windows AD user logon information and sending it to the FortiGate unit. It is particularly useful in large installations with several FortiGate units. For more information, see the [FortiAuthenticator Administration Guide](#).

## FSSO for Microsoft Exchange Server

As of FortiOS 5.4, FSSO supports monitoring Microsoft Exchange Server. This is useful for situations when the user accesses the domain account to view their email, even when the client device might not be in the domain.

Support for the Exchange server is configured on the Back-end FSSO collector agent. For more information on the collector agent, see [Collector agent installation](#):

1. On the FSSO collector agent, go to **Advanced Settings > Exchange Server**.
2. Select **Add** and enter the following information and select **OK**:

<b>Domain Name</b>	Enter your domain name.
<b>Server IP/Hostname</b>	Enter the IP address or the hostname of your exchange server.
<b>Polling forwarded event log</b>	This option for scenarios when you do not want that CA polls the Exchange Server logs directly. In this case you need to configure event log forwarding on the Exchange server. Exchange event logs can be forwarded to any member server. If you enable this, instead of the IP of the Exchange server configured in the previous step, you must then configure the IP of this member server. CA will then contact the member server.
<b>Ignore Name</b>	<p>Because CA will also check Windows log files for logon events and when a user authenticates to Exchange Server there is also a logon event in Windows event log, which CA will read and this will overwrite the Exchange Server logon event (ESEventLog) on CA. So it is recommended to set the ignore list to the domain the user belongs to.</p> <p>To do so, enter the domain name in the <b>Ignore Name</b> field and select <b>Add</b>.</p>

## FSSO for Windows AD

FSSO for Windows AD requires at least one Collector agent. Domain Controller agents may also be required depending on the Collector agent working mode. There are two working modes to monitor user logon activity: DC Agent mode or Polling mode.

### Collector agent DC Agent mode versus Polling mode

	DC Agent mode	Polling Mode
<b>Installation</b>	Complex — Multiple installations: one agent per DC plus Collector agent, requires a reboot	Easy — Only Collector agent installation, no reboot required

	DC Agent mode	Polling Mode
<b>Resources</b>	Shares resources with DC system	Has own resources
<b>Network load</b>	Each DC agent requires minimum 64kpbs bandwidth, adding to network load	Increase polling period during busy period to reduce network load
<b>Level of Confidence</b>	Captures all logons	Potential to miss a login if polling period is too great

## DC Agent mode

DC Agent mode is the standard mode for FSSO. In DC Agent mode, a Fortinet authentication agent is installed on each domain controller. These DC agents monitor user logon events and pass the information to the Collector agent, which stores the information and sends it to the FortiGate unit.

The DC agent installed on the domain controllers is not a service like the Collector agent — it is a DLL file called `dcagent.dll` and is installed in the `Windows\system32` directory. It must be installed on all domain controllers of the domains that are being monitored.

## FSSO in DC agent mode

DC Agent mode provides reliable user logon information, however you must install a DC agent on every domain controller. A reboot is needed after the agent is installed. Each installation requires some maintenance as well. For these reasons it may not be possible to use the DC Agent mode.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality. You can optionally configure traffic shapers on the FortiGate unit to ensure this minimum bandwidth is guaranteed for the domain controller connections.

## Polling mode

In Polling mode there are three options — NetAPI polling, Event log polling, and Event log using WMI. All share the advantages of being transparent and agentless.

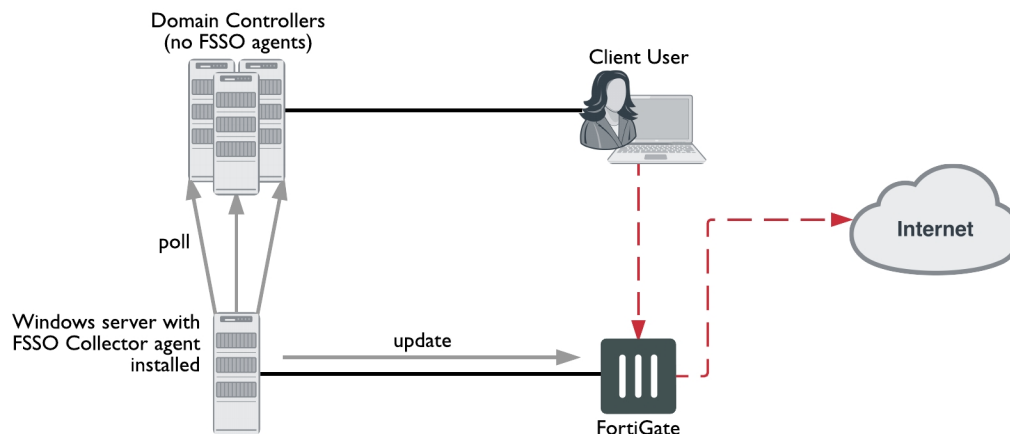

NetAPI polling is used to retrieve server logon sessions. This includes the logon event information for the Controller agent. NetAPI runs faster than Event log polling but it may miss some user logon events under heavy system load. It requires a query round trip time of less than 10 seconds.

Event log polling may run a bit slower, but will not miss events, even when the installation site has many users that require authentication. It does not have the 10 second limit on NetAPI polling. Event log polling requires fast network links. Event log polling is required if there are Mac OS users logging into Windows AD.

Event log using WMI polling: WMI is a Windows API to get system information from a Windows server, CA is a WMI client and sends WMI queries for user logon events to DC, which in this case is a WMI server. Main advantage in this mode is that CA does not need to search security event logs on DC for user logon events, instead, DC returns all requested logon events via WMI. This also reduces network load between CA and DC.

In Polling mode, the Collector agent polls port 445 of each domain controller for user logon information every few seconds and forwards it to the FortiGate unit. There are no DC Agents installed, so the Collector agent polls the domain controllers directly.

### FSSO in Polling mode

A major benefit of Polling mode is that no FSSO DC Agents are required. If it is not possible to install FSSO DC Agents on your domain controllers, this is the alternate configuration available to you. Polling mode results in a less complex install, and reduces ongoing maintenance. The minimum permissions required in Polling mode are to read the event log or call NetAPI.

### Collector agent AD Access mode - Standard versus Advanced

The Collector agent has two ways to access Active Directory user information. The main difference between Standard and Advanced mode is the naming convention used when referring to username information.

Standard mode uses regular Windows convention: Domain\Username. Advanced mode uses LDAP convention: CN=User, OU=Name, DC=Domain.

If there is no special requirement to use LDAP— best practices suggest you set up FSSO in Standard mode. This mode is easier to set up, and is usually easier to maintain and troubleshoot.

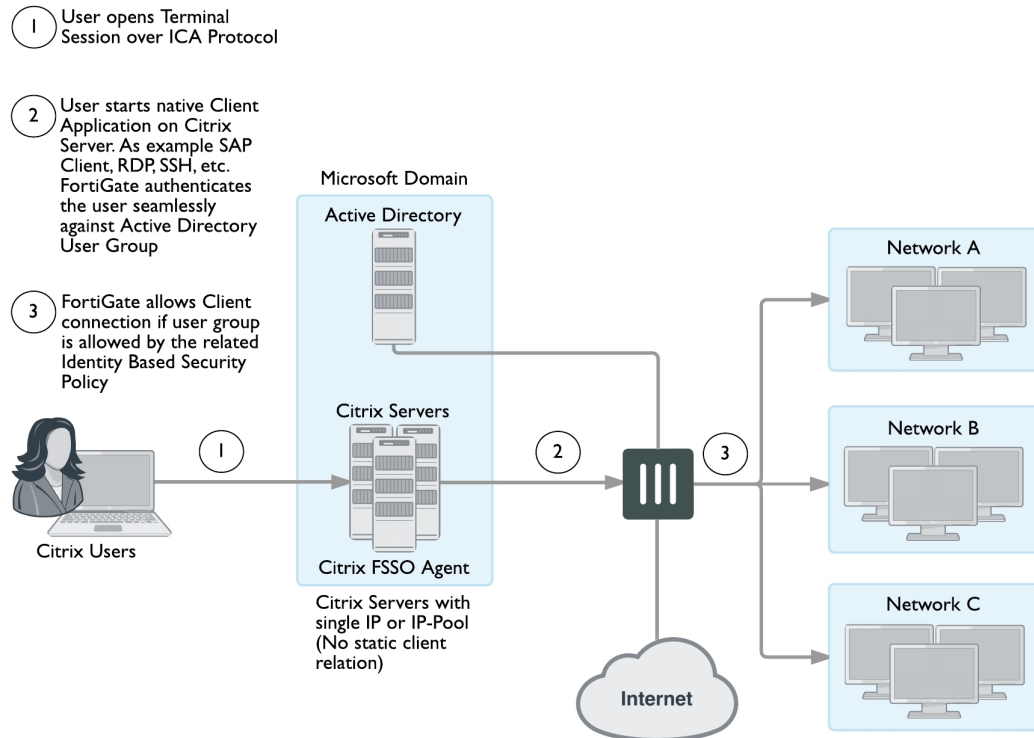

Standard and advanced modes have the same level of functionality with the following exceptions:

- Users have to create Group filters on the Collector agent. This differs from Advanced mode where Group filters are configured from the FortiGate unit. Fortinet strongly encourages users to create filters from CA.
- Advanced mode supports nested or inherited groups. This means that users may be a member of multiple monitored groups. Standard mode does not support nested groups so a user must be a direct member of the group being monitored.

## FSSO for Citrix

Citrix users can enjoy a similar Single Sign-On experience as Windows AD users. The FSSO TS agent installed on each Citrix server provides user logon information to the FSSO Collector agent on the network. The FortiGate unit uses this information to authenticate the user in security policies.

### Citrix SSO topology

Citrix users do not have unique IP addresses. When a Citrix user logs on, the TS agent assigns that user a range of ports. By default each user has a range of 200 ports.

## FSSO for Novell eDirectory

FSSO in a Novell eDirectory environment works similar to the FSSO Polling mode in the Windows AD environment. The eDirectory agent polls the eDirectory servers for user logon information and forwards the information to the FortiGate unit. There is no need for the Collector agent.

When a user logs on at a workstation, FSSO:

- detects the logon event by polling the eDirectory server and records the IP address and user ID,
- looks up in the eDirectory which groups this user belongs to,
- sends the IP address and user groups information to the FortiGate unit.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

FSSO is supported on the Novell E-Directory 8.8 operating system.

For a Novell network, there is only one FSSO component to install — the eDirectory agent. In some cases, you also need to install the Novell Client.

## **FSSO security issues**

When the different components of FSSO are communicating there are some inherent security features.

FSSO installation requires an account with network admin privileges. The security inherent in these types of accounts helps ensure access to FSSO configurations is not tampered with.

User passwords are never sent between FSSO components. The information that is sent is information to identify a user including the username, group or groups, and IP address.

NTLM uses base-64 encoded packets, and uses a unique randomly generated challenge nonce to avoid sending user information and password between the client and the server.

## **FSSO NTLM authentication support**

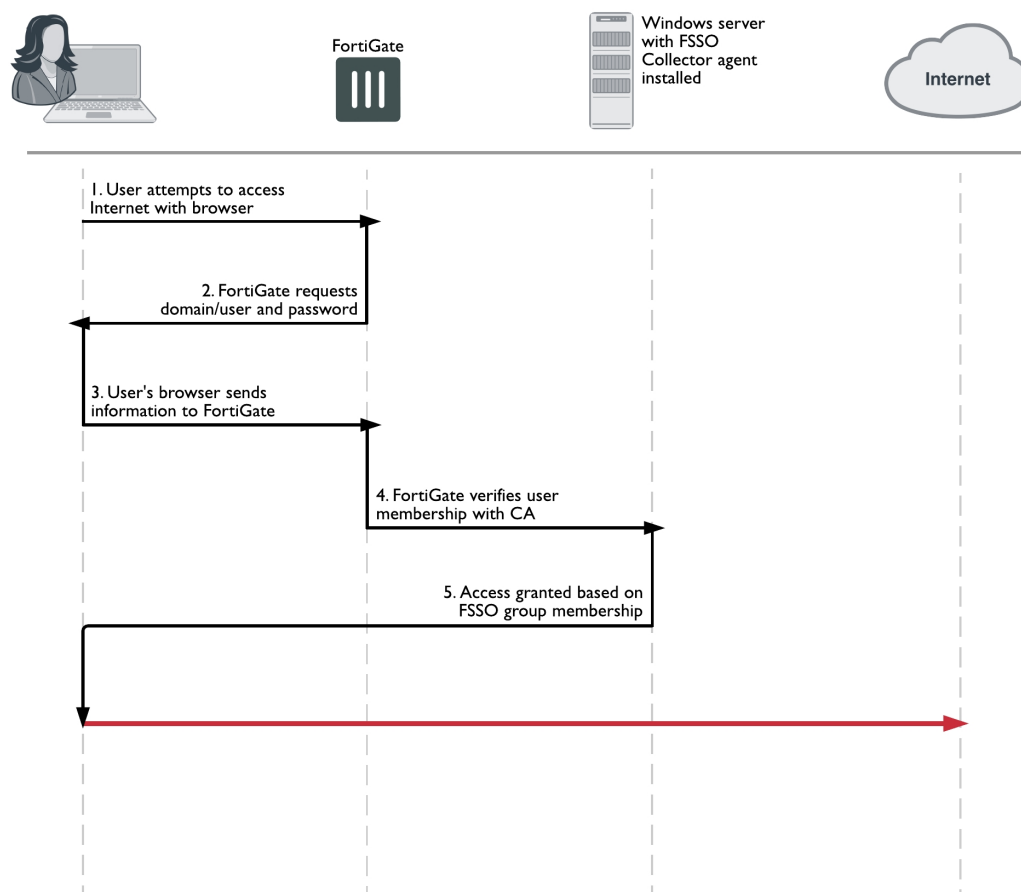

In a Windows AD network, FSSO can also provide NTLM authentication service to the FortiGate unit. When the user makes a request that requires authentication, the FortiGate unit initiates NTLM negotiation with the client browser. The FortiGate unit does not process the NTLM packets itself. Instead, it forwards all the NTLM packets to the FSSO service to process.

NTLM has the benefit of not requiring an FSSO agent, but it is not transparent to users, and the user's web browser must support NTLM.

The NTLM protocol protects the user's password by not sending it over the network. Instead, the server sends the client a random number that the client must encrypt with the hash value of the user's password. The server compares the result of the client's encryption with the result of its own encryption. The two will match only if both parties used the same password.

## NTLM authentication

If the NTLM authentication with the Windows AD network is successful, and the user belongs to one of the groups permitted in the applicable security policy, the FortiGate unit allows the connection but will require authentication again in the future when the current authentication expires.

Fortinet has tested NTLM authentication with Internet Explorer and Firefox browsers.

## NTLM in a multiple domain environment

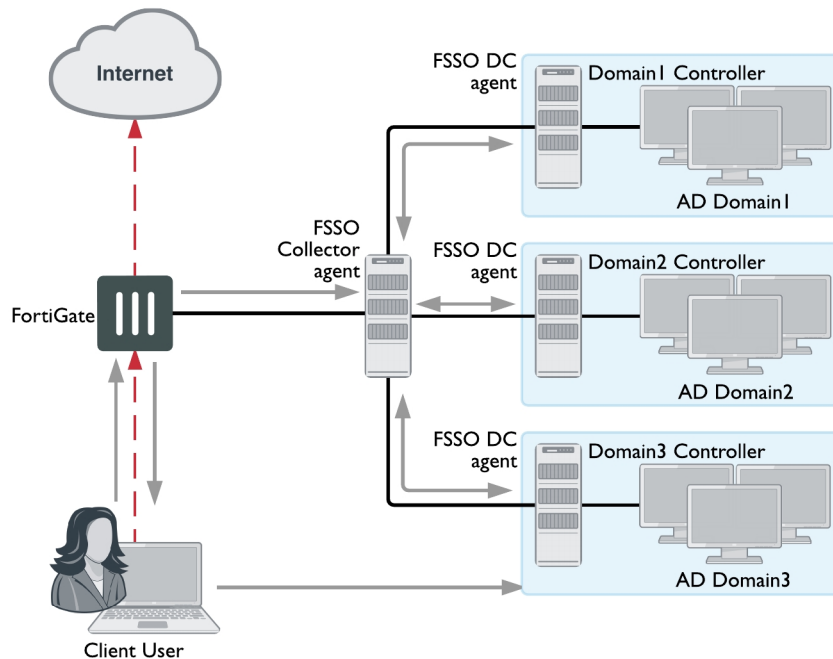

In a multiple domain environment for NTLM, the important factor is that there is a trust relation between the domains. In a forest, this relation is automatically created. So you can install FSSO agent on one of the domain controllers without worry.

But in case of multiple domains that are not in a forest, you need to create a trust relation between the domains. If you do not want to have a trust relation between your multiple domains, you need to use FSAE 4.0 MR1 and the DC agent needs to be installed once on each domain. Then you can use security policies to configure server access.

In the figure below, three domains are shown connected to the FSSO Collector agent server. The Client logs on to their local Domain Controller, which then sends the user logon event information to the Collector Agent. When the Client attempts to access the Internet, the FortiGate unit contacts the Collector Agent for the logon information, sees the Client is authenticated, and allows access to the Internet. There are multiple domains each

with a domain controller agent (DCagent) that sends logon information to the Collector agent. If the multiple domains have a trust relationship, only one DCagent is required instead of one per domain.

### FSSO NTLM with multiple domains not in a forest

### Understanding the NTLM authentication process

1. The user attempts to connect to an external (internet) HTTP resource. The client application (browser) on the user's computer issues an unauthenticated request through the FortiGate unit.
2. The FortiGate is aware that this client has not authenticated previously, so responds with a 401 Unauthenticated status code, and tells the client which authentication method to reply with in the header: Proxy-Authenticated: NTLM. Then the initial session is dismantled.
3. The client application connects again to the FortiGate, and issues a GET-request, with a Proxy-Authorization: NTLM <negotiate string> header. <negotiate-string> is a base64-encoded NTLM Type 1 negotiation packet.
4. The FortiGate unit replies with a 401 "proxy auth required" status code, and a Proxy-Authenticate: NTLM <challenge string> (a base 64-encoded NTLM Type 2 challenge packet). In this packet is the challenge nonce, a random number chosen for this negotiation that is used once and prevents replay attacks.

The TCP connection must be kept alive, as all subsequent authentication-related information is tied to the TCP connection. If it is dropped, the authentication process must start again from the beginning.

5. The client sends a new GET-request with a header: Proxy-Authenticate: NTLM <authenticate string>, where <authenticate string> is a NTLM Type 3 Authentication packet that contains:

- username and domain
  - the challenge nonce encoded with the client password (it may contain the challenge nonce twice using different algorithms).
6. If the negotiation is successful and the user belongs to one of the groups permitted in the security policy, the connection is allowed. Otherwise, the FortiGate unit denies the authentication by issuing a 401 return code and prompts for a username and password. Unless the TCP connection is broken, no further credentials are sent from the client to the proxy.

If the authentication policy reaches the authentication timeout period, a new NTLM handshake occurs.

## Agentless NTLM support

Agentless NTLM authentication can be configured directly from the FortiGate to the Domain Controller via SMB protocol (no agent is required).

Note that this authentication method is only supported for proxy policies.

### Syntax

Note that `domain-controller` is only available when `method` is set to `ntlm` and/or `negotiate-ntlm` is set to `enable`.

```
config authentication scheme
  edit <name>
    set method ntlm
    set domain-controller <dc-setting>
  next
end

config user domain-controller
  edit <name>
    set ip-address <dc-ip>
    set port <port> - default = 445
    set domain-name <dns-name>
    set ldap-server <name>
  next
end
```

## Agent installation

After reading the appropriate sections of [Introduction to agent-based FSSO on page 503](#) to determine which FSSO agents you need, you can proceed to perform the necessary installations.

Ensure you have administrative rights on the servers where you are installing FSSO agents. It is best practice to install FSSO agents using the built-in local administrator account. Optionally, you can install FSSO without an admin account. See [Installing FSSO without using an administrator account on page 515](#).

In Windows 2008 by default, you do not have administrative user rights if you are logged on as a user other than as the built-in administrator, even if you were added to the local Administrators group on the computer.

The FSSO installer first installs the Collector agent. You can then continue with installation of the DC agent, or you can install it later by going to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**. The installer will install a DC agent on the domain controllers of all of the trusted domains in your network.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality. Traffic shapers configured on the FortiGate can help guarantee these minimum bandwidths.

---

## Collector agent installation

To install FSSO, you must obtain the FSSO\_Setup file from the [Fortinet Support web site](#). This is available as either an executable (.exe) or a Microsoft Installer (.msi) file. Then you follow these two installation procedures on the server that will run the Collector agent. This can be any server or domain controller that is part of your network. These procedures also install the DC Agent on all of the domain controllers in your network.

---

IPv6 source addresses can be configured for connecting to an FSSO agent.

---

### To install the Collector agent:

1. Create an account with administrator privileges and a password that does not expire. See Microsoft Advanced Server documentation for help with this task.  
To use a non-admin read only account, see [Installing FSSO without using an administrator account on page 515](#).
2. Log on to the account that you created in Step 1.
3. Double-click the `FSSOSetup.exe` file.  
The Fortinet SSO Collector Agent Setup Wizard starts.
4. Select **Next**.
5. Read and accept the license agreement. Select **Next**.
6. Optionally, you can change the installation location. Select **Next**.
7. Optionally, change the **User Name**.
8. By default, the agent is installed using the currently running account. If you want FSSO to use another existing admin account, change the **User Name** using the format `DomainName \ UserName`. For example if the account is `jsmith` and the domain is **example\_corp** you would enter `example_corp\jsmith`.
9. In the **Password** field, enter the password for the account listed in the **User Name** field.
10. Select **Next**.
11. Enable as needed:
  - Monitor user logon events and send the information to the FortiGate unit
  - Serve NTLM authentication requests coming from FortiGateBy default, both methods are enabled. You can change these options after installation.
12. Select the access method to use for Windows Directory:
13. Select **Standard** to use Windows domain and username credentials.
14. Select **Advanced** if you will set up LDAP access to Windows Directory.  
See [Collector agent AD Access mode - Standard versus Advanced on page 507](#).

15. Select **Next** and then select **Install**.

If you want to use DC Agent mode, ensure that **Launch DC Agent Install Wizard** is selected. This will start DC agent installation immediately after you select **Finish**.

16. Select **Finish**.

If you see an error such as Service Fortinet Single Sign On agent (service\_FSAE) failed to start, there are two possible reasons for this. Verify the user account you selected has sufficient privileges to run the FSSO service. Also verify the computer system you are attempting to install on is a supported operating system and version.

---

## DC agent installation

The FSSO\_Setup file contains both the Collector agent and DC Agent installers, but the DC Agent installer is also available separately as either a .exe or .msi file named DCAgent\_Setup.

### To install the DC Agent

1. If you have just installed the Collector agent, the FSSO - Install DC Agent wizard starts automatically. Otherwise, go to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**.
2. Select **Next**.
3. Read and accept the license agreement. Select **Next**.
4. Optionally, you can change the installation location. Select **Next**.
5. Enter the **Collector agent IP address**.
6. If the Collector agent computer has multiple network interfaces, ensure that the one that is listed is on your network. The listed **Collector agent listening port** is the default. Only change this if the port is already used by another service.
7. Select **Next**.
8. Select the domains to monitor and select **Next**.
9. If any of your required domains are not listed, cancel the wizard and set up the proper trusted relationship with the domain controller. Then run the wizard again by going to **Start > Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent**.
10. Optionally, select users that you do not want monitored. These users will not be able to authenticate to FortiGate units using FSSO. You can also do this later. See [Configuring the FSSO Collector agent for Windows AD on page 517](#).
11. Select **Next**.
12. Optionally, clear the check boxes of domain controllers on which you do not want to install the DC Agent.
13. Select the **Working Mode** as DC Agent Mode. While you can select Polling Mode here, in that situation you would not be installing a DC Agent. For more information, see [DC Agent mode on page 506](#) and [Polling mode on page 506](#).
14. Select **Next**.
15. Select **Yes** when the wizard requests that you reboot the computer.

If you reinstall the FSSO software on this computer, your FSSO configuration is replaced with default settings.

---

If you want to create a redundant configuration, repeat the Collector agent installation procedure on at least one other Windows AD server.

When you start to install a second Collector agent, cancel the Install Wizard dialog appears the second time. From the configuration GUI, the monitored domain controller list will show your domain controllers un-selected. Select the ones you wish to monitor with this Collector agent, and select **Apply**.

---

Before you can use FSSO, you need to configure it on both Windows AD and on the FortiGate units. [Configuring FSSO on FortiGate units on page 537](#) will help you accomplish these two tasks.

### Installing FSSO without using an administrator account

Normally when installing services in Windows, it is best to use the Domain Admin account, as stated earlier. This ensures installation goes smoothly and uninterrupted, and when using the FSSO agent there will be no permissions issues. However, it is possible to install FSSO with a non-admin account in Windows 2003 or 2008 AD.

The following instructions for Windows 2003 are specific to the event log polling mode only. Do not use this procedure with other FSSO configurations.

---

### Windows 2003

There are two methods in Windows 2003 AD for installing FSSO without an admin account — add the non-admin user to the security log list, and use a non-admin account with read-only permissions. A problem with the first method is that full rights (read, write, and clear) are provided to the event log. This can be a problem when audits require limited or no write access to logs. In those situations, the non-admin account with read-only permissions is the solution.

#### To add the non-admin user account to the Windows 2003 security log list :

1. Go to **Default Domain Controller Security Settings > Security Settings > User Rights Assignment > Manage auditing and security log**.
2. Add the user account to this list.
3. Repeat these steps on every domain controller in Windows 2003 AD.  
A reboot is required.

#### To use a non-admin account with read-only permissions to install FSSO on Windows 2003:

The following procedure provides the user account specified with read only access to the Windows 2003 AD Domain Controller Security Event Log which allows FSSO to function.

1. Find out the SID of the account you intend to use.  
Tools for this can be downloaded for free from <http://technet.microsoft.com/en-us/sysinternals/bb897417>.
2. Then create the permission string. For example:
  - (A;;0x1;;;S-1-5-21-4136056096-764329382-1249792191-1107)
  - A means Allow,

- 0x1 means Read, and
  - S-1-5-21-4136056096-764329382-1249792191-1107 is the SID.
3. Then, append it to the registry key:  
HKEY\_LOCAL\_MACHINE\System\CurrentControlSet\Services\Eventlog\Security\CustomSD
  4. Repeat these steps on every domain controller in Windows 2003 AD.  
A reboot is required.

## Windows 2008

In Windows 2008 AD, if you do not want to use the Domain Admin account then the user account that starts the FSSO agent needs to be added to the Event Log Readers group.

When the user is added to the Event Log Readers group, that user is now allowed to have read only access to the event log and this is the minimal rights required for FSSO to work.

## Citrix TS agent installation

To install the Citrix TS agent, you must obtain the TSAgent\_Setup file from the [Fortinet Support web site](#). Perform the following installation procedure on the Citrix server.

### To install the FSSO TS agent:

1. On the Citrix server, create an account with administrator privileges and a password that does not expire. See Citrix documentation for more information.
2. Log on to the account that you created in step 1.
3. Double-click the TSAgent\_Setup installation file.  
The Fortinet SSO Terminal Server Agent Setup Wizard starts.
4. Select **Next**.
5. Read and accept the license agreement. Select **Next**.
6. Optionally, you can change the installation location. Select **Next**.
7. Verify that **This Host IP Address** is correct.
8. In the **FSSO Collector Agent List**, enter the IP address(es) of your Collector Agents.
9. Select **Next** and then select **Install**.  
The TS agent is installed.
10. Select **Finish**.

## Novell eDirectory agent installation

To install the eDirectory agent, you must obtain the FSSO\_Setup\_eDirectory file from the [Fortinet Support web site](#). Perform the following installation procedure on the computer that will run the eDirectory agent. This can be any server or domain controller that is part of your network. You will need to provide some setup information.

### To install the FSSO eDirectory agent:

1. Create an account with administrator privileges and a password that does not expire. See Novell documentation for more information.
2. Log on to the account that you created in step 1.
3. Double-click the FSSO\_Setup\_edirectory file to start the installation wizard.
4. Select **Next**.

5. Read and accept the license agreement. Select **Next**.
6. Optionally, change the installation location. Select **Next**.
7. Enter:

eDirectory Server	
Server Address	Enter the IP address of the eDirectory server.
Use secure connection (SSL)	Select to connect to the eDirectory server using SSL security.
Search Base DN	Enter the base Distinguished Name for the user search.

eDirectory Authentication	
Username	Enter a username that has access to the eDirectory, using LDAP format.
User password	Enter the password.

8. Select **Next**.
9. Select **Install**. When the installation completes, select **Finish**.

## Updating FSSO agents on Windows AD

After FSSO is installed on your network, you may want to upgrade to a newer version. The following procedure helps ensure you have a trouble free upgrade. How you update FSSO depends on if you are using polling mode or DC Agent mode.

For polling mode, since there are no DC agents you only need to upgrade the Collector. However in DC Agent mode, each DC Agent must be updated as well.

### To update FSSO in DC Agent mode:

1. Go to the system32 directory on all DC's and rename the `dcagent.dll` file to `dcagent.dll.old`. This ensures the when the upgrade is pushed to the DC it does not overwrite the old file. If there are any problems this makes it easy to revert to the old version.
2. Run the FSSO setup .exe file to update the collector. When this is completed, ignore any reboot message.
3. Go to **Programs > Fortinet > Fortinet Single Sign On Agent > Install DC Agent** and push the DC agent out to all servers. All DC's will now need to be rebooted so that the new DLL file is loaded.
4. After the reboot, go to all DC's and delete the `dcagent.dll.old` files.

## Configuring the FSSO Collector agent for Windows AD

On the FortiGate unit, security policies control access to network resources based on user groups. With Fortinet Single Sign On, this is also true but each FortiGate user group is associated with one or more Windows AD user groups. This is how Windows AD user groups get authenticated in the FortiGate security policy.

Fortinet Single Sign On sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate units.

To avoid this problem, you can configure the Fortinet Single Sign On Collector agent to send logon information only for groups named in the FortiGate unit's security policies. See [Configuring FortiGate group filters on page 524](#).

On each server with a Collector agent, you will be

- [Configuring Windows AD server user groups](#)
- [Configuring Collector agent settings](#), including the domain controllers to be monitored
- [Selecting Domain Controllers and working mode for monitoring](#)
- [Configuring Directory Access settings](#)
- [Configuring the Ignore User List](#)
- [Configuring FortiGate group filters for each FortiGate unit](#)
- [Configuring FSSO ports](#)
- [Configuring alternate user IP address tracking](#)
- [Viewing FSSO component status](#)

## Configuring Windows AD server user groups

FortiGate units control network resource access at the group level. All members of a user group have the same network access as defined in FortiGate security policies.

You can use existing Windows AD user groups for authentication to FortiGate units if you intend that all members within each group have the same network access privileges.

Otherwise, you need to create new user groups for this purpose.

If you change a user's group membership, the change does not take effect until the user logs off and then logs on again.

The FSSO Agent sends only Domain Local Security Group and Global Security Group information to FortiGate units. You cannot use Distribution group types for FortiGate access. No information is sent for empty groups.

---

Refer to Microsoft documentation for information about creating and managing Windows AD user groups.

## Configuring Collector agent settings

You need to configure which domain controllers the Collector agent will use and which domains to monitor for user logons. You can also alter default settings and settings you made during installation. These tasks are accomplished by configuring the FSSO Collector Agent, and selecting either Apply to enable the changes.

At any time to refresh the FSSO Agent settings, select Apply.

### To configure the Collector agent:

1. From the Start menu, select **Programs > Fortinet > Fortinet Single Sign-On Agent > Configure Fortinet Single Sign-On Agent**.
2. Enter the following information.

<b>Monitoring user logon events</b>	By default, this is enabled to automatically authenticate users as they log on to the Windows domain. Disable the Monitor feature only if you have a large network where this feature will slow responses too much.
<b>Support NTLM authentication</b>	By default, this is enabled to facilitate logon of users who are connected to a domain that does not have the FSSO DC Agent installed. Disable NTLM authentication only if your network does not support NTLM authentication for security or other reasons.
<b>Collector Agent Status</b>	Shows RUNNING when Collector agent is active.
<b>Listening ports</b>	You can change FSSO Collector Agent related port numbers if necessary.
<b>FortiGate</b>	TCP port for FortiGate units. Default 8000.
<b>DC Agent</b>	UDP port for DC Agents. Default 8002.
<b>Logging</b>	
<b>Log level</b>	Select the minimum severity level of logged messages.

<b>Log file size limit (MB)</b>	Enter the maximum size for the log file in MB. Default is 10.
<b>View Log</b>	View all Fortinet Single Sign On agent logs.
<b>Log logon events in separate logs</b>	<p>Record user login-related information separately from other logs. The information in this log includes:</p> <ul style="list-style-type: none"> <li>• data received from DC agents</li> <li>• user logon/logoff information</li> <li>• workstation IP change information</li> <li>• data sent to FortiGate units</li> </ul>
<b>View Logon Events</b>	If <b>Log logon events in separate logs</b> is enabled, you can view user login-related information.
<b>Authentication</b>	
<b>Require authenticated connection from FortiGate</b>	Select to require the FortiGate unit to authenticate before connecting to the Collector agent.
<b>Password</b>	Enter the password that FortiGate units must use to authenticate. The maximum password length is 15 characters. The default password is "fortinetcanada". It is highly recommended to modify this password.
<b>Timers</b>	
<b>Workstation verify interval (minutes)</b>	<p>Enter the interval in minutes at which the Fortinet Single Sign On Collector agent connects to client computers to determine whether the user is still logged on. The default is every 5 minutes. The interval may be increased if your network has too much traffic.</p> <p><b>Note:</b> This verification process creates security log entries on the client computer.</p> <p>If ports 139 or 445 cannot be opened on your network, set the interval to 0 to prevent checking. See <a href="#">Configuring FSSO ports on page 526</a>.</p>
<b>Dead entry timeout interval</b>	<p>Enter the interval in minutes after which Fortinet Single Sign On Agent purges information for user logons that it cannot verify. The default is 480 minutes (8 hours).</p> <p>Dead entries usually occur because the computer is unreachable (such as in standby mode or disconnected) but the user has not logged off. A common reason for this is when users forget to logoff before leaving the office for the day.</p> <p>You can also prevent dead entry checking by setting the interval to 0.</p>

<b>IP address change verify interval</b>	<p>Fortinet Single Sign On Agent periodically checks the IP addresses of logged-in users and updates the FortiGate unit when user IP addresses change. IP address verification prevents users from being locked out if they change IP addresses, as may happen with DHCP assigned addresses.</p> <p>Enter the verification interval in seconds. The default is 60 seconds. You can enter 0 to prevent IP address checking if you use static IP addresses.</p> <p>This does not apply to users authenticated through NTLM.</p>
<b>Cache user group lookup result</b>	<p>Enable caching.</p> <p>Caching can reduce group lookups and increase performance.</p>
<b>Cache expire in (minutes)</b>	<p>Fortinet Single Sign On Agent caches group information for logged-in users.</p> <p>Enter the duration in minutes after which the cache entry expires. If you enter 0, the cache never expires.</p> <p>A long cache expire interval may result in more stale user group information. This can be an issue when a user's group information is changed.</p>
<b>Clear Group Cache</b>	<p>Clear group information of logged-in users.</p> <p>This affects all logged-in users, and may force them to re-login.</p>

3. You can select **Save&Close** now or leave the agent configuration window open to complete additional configuration in the following sections.

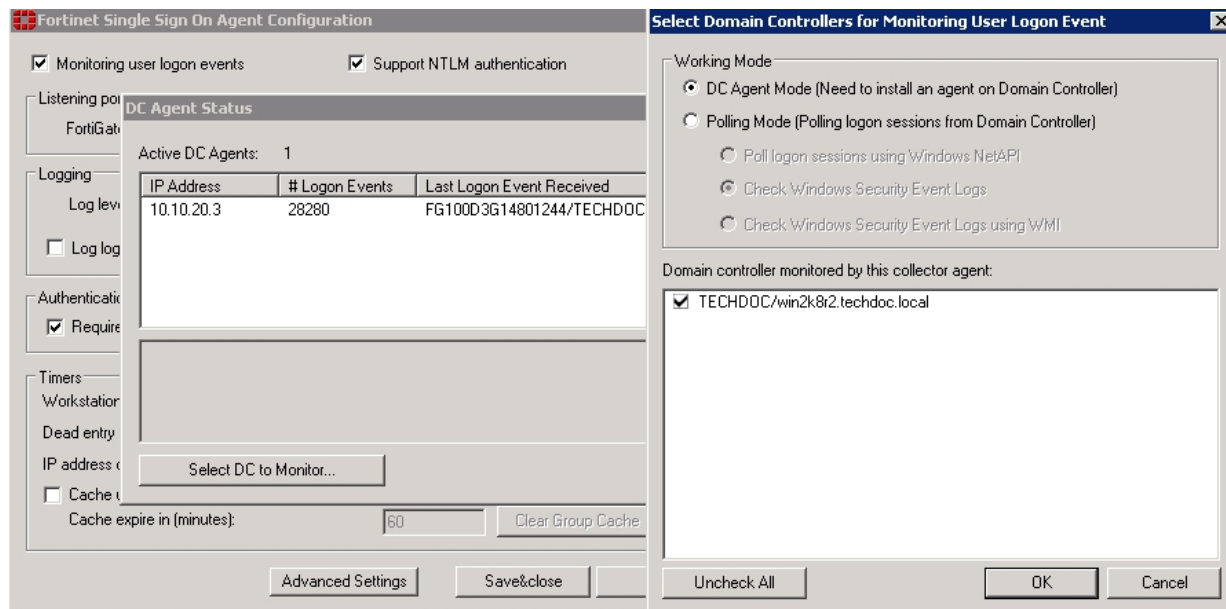

To view the version and build number information for your FSSO Collector Agent configuration, selecting the Fortinet icon in the upper left corner of the Collector agent Configuration screen and select **About Fortinet Single Sign On Agent configuration**.

## Selecting Domain Controllers and working mode for monitoring

You can change which DC agents are monitored or change the working mode for logon event monitoring between DC agent mode and polling mode.

When polling mode is selected, it will poll port 445 of the domain controller every few seconds to see who is logged on.

1. From the Start menu select **Programs > Fortinet Fortinet Single Sign-On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Monitored DCs**.
3. Select **Select DC to Monitor**.

#### 4. Choose the **Working Mode**:

- **DC Agent mode** — a Domain Controller agent monitors user logon events and passes the information to the Collector agent. This provides reliable user logon information, however you must install a DC agent on every domain controller in the domain.
- **Polling mode** — the Collector agent polls each domain controller for user logon information. Under heavy system load this might provide information less reliably. However installing a DC agent on each domain controller is not required in this mode.

#### 5. You also need to choose the method used to retrieve logon information:

- Poll logon sessions using Windows NetAPI
- Check Windows Security Event Logs
- Check Windows Security Event Logs using WMI

For more information about these options, see [Polling mode on page 506](#).

#### 6. Select **OK**.

#### 7. Select **Close**.

#### 8. Select **Save & Close**.

## Configuring Directory Access settings

The FSSO Collector Agent can access Windows Active Directory in one of two modes:

- **Standard** — the FSSO Collector Agent receives group information from the Collector agent in the **domain\user** format. This option is available on FortiOS 3.0 and later.
- **Advanced** — the FSSO Collector Agent obtains user group information using LDAP. The benefit of this method is that it is possible to nest groups within groups. This option is available on FortiOS 3.0 MR6 and later. The group information is in standard LDAP format.

If you change AD access mode, you must reconfigure your group filters to ensure that the group information is in the correct format.

**To configure Directory Access settings:**

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Set Directory Access Information**.  
The **Set Directory Access Information** dialog box opens.
3. From the **AD access mode** list, select either **Standard** or **Advanced**.
4. If you selected Advanced AD access mode, select **Advanced Setting** and configure the following settings and then select **OK**:

<b>AD server address</b>	Enter the address of your network's global catalog server.
<b>AD server port</b>	The default AD server port is 3268. This must match your server port.
<b>BaseDN</b>	Enter the Base distinguished name for the global catalog. This is the point in the tree that will be considered the starting point by default-See following example.
<b>Username</b>	If the global catalog accepts your Fortinet Single Sign On Agent agent's credentials, you can leave these fields blank. Otherwise, enter credentials for an account that can access the global catalog.
<b>Password</b>	

**BaseDN example**

An example DN for Training Fortinet Canada is `ou=training, ou=canada, dc=fortinet, dc=com`. If you set the **BaseDN** to `ou=canada, dc=fortinet, dc=com` then when Fortinet Single Sign On Agent is looking up user credentials, it will only search the Canada organizational unit, instead of all the possible countries in the company. Its a short cut to entering less information and faster searches.

However, you may have problems if you narrow the BaseDN too much when you have international employees from the company visiting different offices. If someone from Fortinet Japan is visiting the Canada office in the example above, their account credentials will not be matched because they are in `ou=japan, dc=fortinet, dc=com` instead of the BaseDN `ou=canada, dc=fortinet, dc=com`. The easy solution is to change the BaseDN to simply be `dc=fortinet, dc=com`. Then any search will check all the users in the company.

**Configuring the Ignore User List**

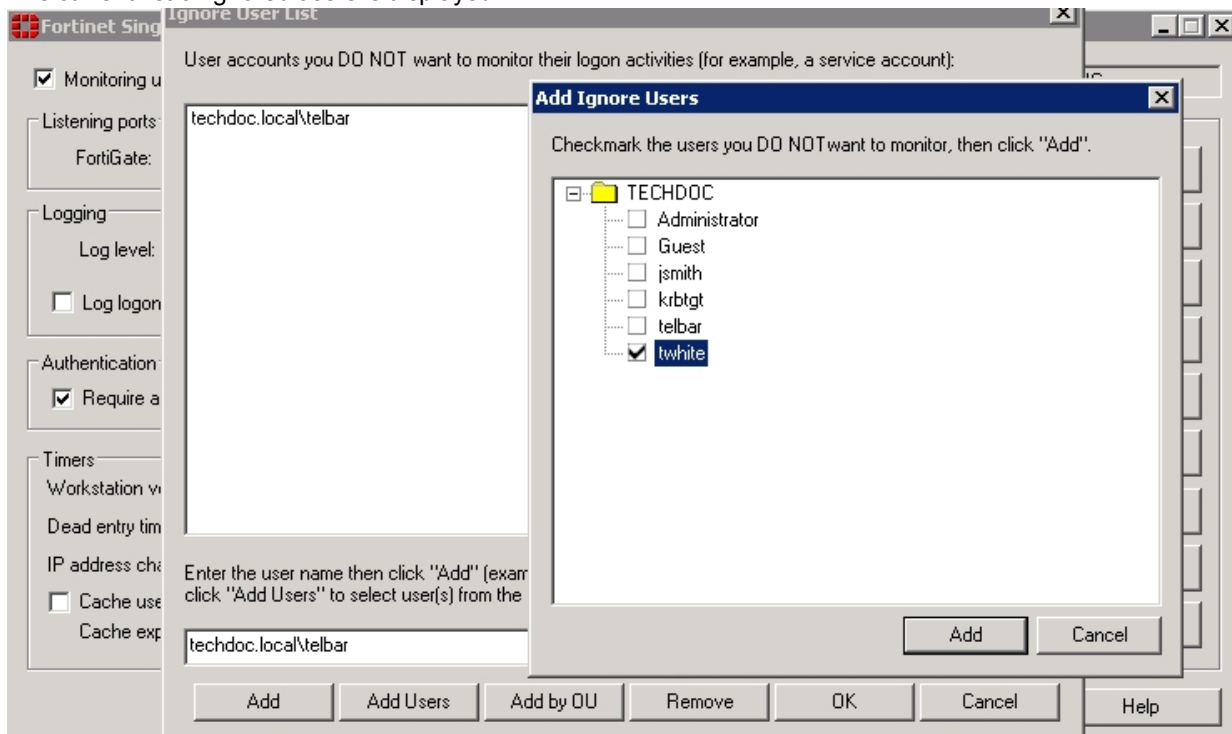

The Ignore User List excludes users that do not authenticate to any FortiGate unit, such as system accounts. The logons of these users are not reported to FortiGate units. This reduces the amount of required resources on the FortiGate unit especially when logging logon events to memory.

**To configure the Ignore User List:**

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.

2. In the **Common Tasks** section, select **Set Ignore User List**.

The current list of ignored users is displayed:

3. Do any of the following:

- To remove a user from the list, select the the username and then select **Remove**. The user's login is no longer ignored.
- To add users to be ignored,
  - enter the username in the format **domain\username** and select **Add** or
  - select **Add Users**, an **Add Ignore Users** window is displayed, checkmark the users you do not want to monitor, then select **Add** or
  - select **Add by OU**, an **Add Ignore Users by OU** window is displayed, select an OU from the directory tree, then select **Add**. All users under the selected OU will be added to the ignore user list.

4. Select **OK**.

## Configuring FortiGate group filters

FortiGate group filters actively control which user logon information is sent to each FortiGate unit. You need to configure the group filter list so that each FortiGate unit receives the correct user logon information for the user groups that are named in its security policies. These group filters help limit the traffic sent to the FortiGate unit, and help limit the logon events logged.

The maximum number of Windows AD user groups allowed on a FortiGate depends on the model. Low end models support 256 Windows AD user groups, where mid and high end models support 1024 groups. This is per VDOM if VDOMs are enabled on the FortiGate unit.

You do not need to configure a group filter on the Collector agent if the FortiGate unit retrieves group information from Windows AD using LDAP. In that case, the Collector agent uses the list of groups you selected on the FortiGate unit as its group filter.

The filter list is initially empty. You need to configure filters for your FortiGate units using the Add function. At a minimum, create a default filter that applies to all FortiGate units without a defined filter.

If no filter is defined for a FortiGate unit and there is no default filter, the Collector agent sends all Windows AD group and user logon events to the FortiGate unit. While this normally is not a problem, limiting the amount of data sent to the FortiGate unit improves performance by reducing the amount of memory the unit uses to store the group list and resulting logs.

#### To configure a FortiGate group filter:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Set Group Filters**.  
The FortiGate Filter List opens. It has the following columns:

<b>FortiGate SN</b>	The serial number of the FortiGate unit to which this filter applies.
<b>Description</b>	An optional description of the role of this FortiGate unit.
<b>Monitored Groups</b>	The Windows AD user groups that are relevant to the security policies on this FortiGate unit.
<b>Add</b>	Create a new filter.
<b>Edit</b>	Modify the filter selected in the list.
<b>Remove</b>	Remove the filter selected in the list.
<b>OK</b>	Save the filter list and exit.
<b>Cancel</b>	Cancel changes and exit.

3. Select **Add** to create a new filter. If you want to modify an existing filter, select it in the list and then select **Edit**.
4. Enter the following information and then select **OK**.

<b>Default filter</b>	Select to create the default filter. The default filter applies to any FortiGate unit that does not have a specific filter defined in the list.
<b>FortiGate Serial Number</b>	Enter the serial number of the FortiGate unit to which this filter applies. This field is not available if Default is selected.
<b>Description</b>	Enter a description of this FortiGate unit's role in your network. For example, you could list the resources accessed through this unit. This field is not available if Default is selected.
<b>Monitor the following groups</b>	The Collector agent sends to the FortiGate unit the user logon information for the Windows AD user groups in this list. Edit this list using the Add, Advanced and Remove buttons.

<b>Add</b>	<p>In the preceding single-line field, enter the Windows AD domain name and user group name, and then select Add. If you don't know the exact name, use the Advanced button instead.</p> <p>The format of the entry depends on the AD access mode (see <a href="#">Configuring Directory Access settings on page 522</a>):</p> <p>Standard: Domain\Group</p> <p>Advanced: cn=group, ou=corp, dc=domain</p>
<b>Advanced</b>	Select <b>Advanced</b> , select the user groups from the list, and then select <b>Add</b> .
<b>Remove</b>	Remove the user groups selected in the monitor list.

## Configuring FSSO ports

For FSSO to function properly a small number of TCP and UDP ports must be open through all firewalls on the network. These ports listed in this section assume the default FSSO ports are used.

### TCP ports for FSSO agent with client computers

Windows AD records when users log on but not when they log off. For best performance, Fortinet Single Sign On Agent monitors when users log off. To do this, Fortinet Single Sign On Agent needs read-only access to each client computer's registry over TCP port 139 or 445. Open at least one of these ports — ensure it is not blocked by firewalls.

If it is not feasible or acceptable to open TCP port 139 or 445, you can turn off Fortinet Single Sign On Agent logoff detection. To do this, set the Collector agent **workstation verify interval** to 0. The FSSO Collector Agent assumes that the logged on computer remains logged on for the duration of the Collector agent dead entry timeout interval — by default this is eight hours.

### Configuring ports on the Collector agent computer

On the computer where you install the Collector agent, you must make sure that the firewall does not block the listening ports for the FortiGate unit and the DC Agent. By default, these are TCP port 8000 and UDP port 8002. For more information about setting these ports, see [Configuring FSSO Advanced Settings on page 532](#).

### Configuring alternate user IP address tracking

In environments where user IP addresses change frequently, you can configure Fortinet Single Sign On Agent to use an alternate method to track user IP address changes. Using this method, Fortinet Single Sign On Agent responds more quickly to user IP address changes because it directly queries workstation IP addresses to match users and IP addresses.

This feature requires FSAE version 3.5.27 or later, Fortinet Single Sign On Agent any version, and FortiOS 3.0 MR7 or later.

**To configure alternate user IP address tracking:**

1. On the computer where the Collector agent is installed, go to **Start > Run**.
2. Enter `regedit` or `regedt32` and select **OK**.  
The Registry Editor opens.
3. Find the registry key `HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\collectoragent`.
4. Set the `supportFSAEauth` value (dword) to `00000001`.  
If needed, create this new dword.
5. Close the Registry Editor.
6. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
7. Select **Apply**.  
The Fortinet Single Sign On Agent service restarts with the updated registry settings.

## Viewing FSSO component status

It is important to know the status of both your Collector agents and DC agents.

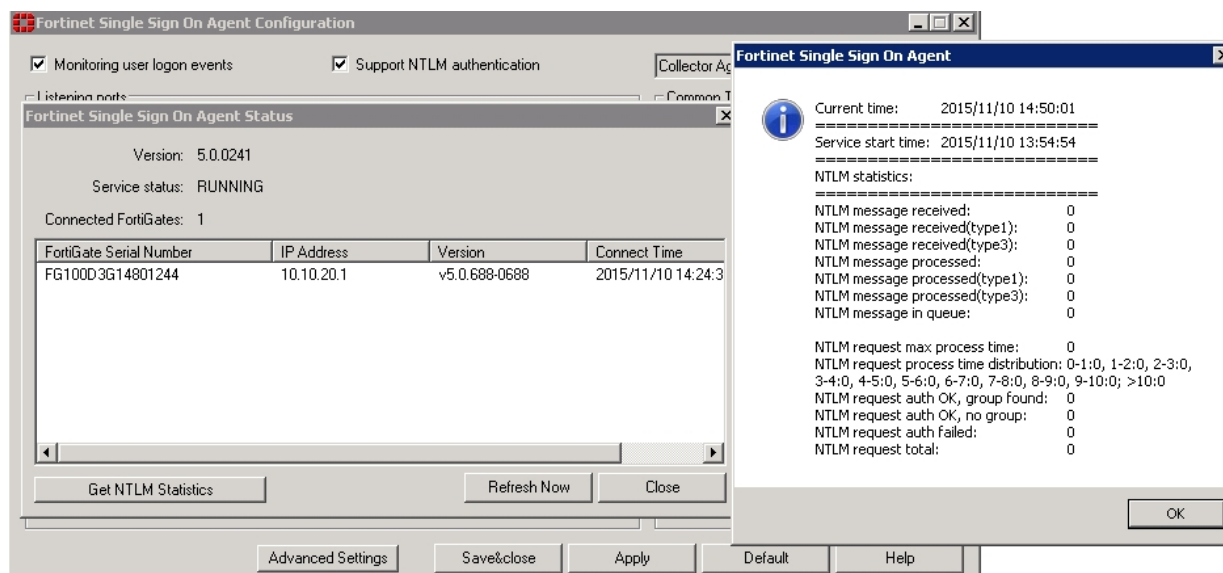

### Viewing Collector agent status

Use the **Show Service Status** to view your Collector agent information in the Status window. The Status window displays:

- the version of the software
- the status of the service
- the number of connected FortiGate units
- connected FortiGate information such as serial number, IP address, and connect time

**To view Collector agent status:**

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Service Status**.  
The Fortinet Single Sign On Collector agent Status window opens.
3. Optionally select **Get NTLM statistics** in the Status window to display NTLM information such as number of messages received, processed, failed, in the queue.

## Viewing DC agent status

Use the **Show Monitored DCs** to view the status of DC agents.

### To view domain controller agent status:

1. From the Start menu select **Programs > Fortinet > Fortinet Single Sign On Agent > Configure Fortinet Single Sign On Agent**.
2. In the **Common Tasks** section, select **Show Monitored DCs**.  
For each DC Agent, the following information is displayed:
  - IP address
  - number of logon events received
  - the last logon event
  - when last logon was received

To change which DC agents are monitored or change the working mode for logon event monitoring, select **Select DC to Monitor**

DC Agent Status			
Active DC Agents: 1			
IP Address	# Logon Events	Last Logon Event Received	Received at
10.10.20.3	350	win2k8r2/KEEPALIVE/5.0.0241	2015/11/10 14:51:11
<div> <div>Select DC to Monitor...</div> <div>Refresh Now</div> <div>Close</div> </div>			

## Configuring the FSSO TS agent for Citrix

The FSSO TS agent works with the same FSSO Collector agent that is used for integration with Windows Active Directory. Install the Collector agent first. Follow the Collector agent installation procedure in [Collector agent installation on page 513](#).

FortiOS 5.6 supports FSSO DC/TS Agent v.5.x.

Configuration steps include:

- Install the Fortinet Citrix FSSO agent on the Citrix server.
- Install the Fortinet FSSO collector on a server on the network.
- Add the Citrix FSSO agent to the FortiGate Single-sign-On configuration.
- Add Citrix FSSO groups and users to an FSSO user group.
- Add an FSSO identity-based security policy that includes the Citrix FSSO user groups.

To change the TS agent configuration, select from the Start menu **Programs > Fortinet > Fortinet Single Sign-On Agent > TSAgent Config**. In addition to the host and Collector agent IP addresses that you set during installation, you can adjust port allocations for Citrix users. When a Citrix user logs on, the TS agent assigns that user a range of ports. By default each user has a range of 200 ports.

**Fortinet SSO Collector Agent IP and Port** needs to point to the current configured listening port on the collector which is port 8002 by default. Though it may be configured to a custom port.

## Configuring the TS agent

**Fortinet SSO Terminal Server Agent Configuration**

Terminal Server Agent Status: RUNNING

**Connection**

This Host IP Address: 172.20.120.52

Fortinet SSO Collector Agent IP and Port: 172.20.120.100  
e.g. 192.168.0.100:8002;172.16.1.200:9999

**Port Allocation**

System Dynamic Allocation Port Range: 1024-5000

Port Allocation Pool (Port Ranges): 5001-65535  
e.g. 20000-39999

Number of Port Per Allocation: 200    Maximum Number of Port Alloc Ranges: 2

**Logging**

☐ Debug   ☐ Info   ☐ Warning   ☒ Error   ☐ None   [View Log](#)

[Default](#)   [Apply](#)   [Save&close](#)

## Configuring FSSO with Novell networks

You need to configure the eDirectory agent for it to communicate with eDirectory servers. You may have provided some of this information during installation.

This section includes:

- [Configuring the eDirectory agent](#)
- [Adding an eDirectory server](#)
- [Configuring a group filter](#)

### Configuring the eDirectory agent

You need to configure the eDirectory agent for it to communicate with eDirectory servers.

**To configure the eDirectory agent:**

1. From the Start menu select **Programs > Fortinet > eDirectory Agent > eDirectory Config Utility**.
2. The eDirectory Agent Configuration Utility dialog opens. Enter the following information and select **OK**.

eDirectory Authentication	
<b>Username</b>	Enter a username that has access to the eDirectory, using LDAP format.
<b>Password</b>	Enter the password.
<b>Listening port</b>	Enter the TCP port on which Fortinet Single Sign On Agent listens for connections from FortiGate units. The default is 8000. You can change the port if necessary.
<b>Refresh interval</b>	Enter the interval in seconds between polls of the eDirectory server to check for new logons. The default is 30 seconds.
FortiGate Connection Authentication	
<b>Require authenticated connection from FortiGate</b>	Select to require the FortiGate unit to authenticate before connecting to the eDirectory Agent.
<b>Password</b>	Enter the password that FortiGate units must use to authenticate. The maximum password length is 15 characters. The default password is "FortinetCanada".
<b>User logon Info Search Method</b>	<p>Select how the eDirectory agent accesses user logon information: <b>LDAP</b> or <b>Native</b> (Novell API). LDAP is the default.</p> <p>If you select <b>Native</b>, you must also have the Novell Client installed on the PC.</p>
Logging	
<b>Log file size limit (MB)</b>	Enter the maximum size for the log file in MB.
<b>View Log</b>	View the current log file.
<b>Dump Session</b>	List the currently logged-on users in the log file. This can be useful for troubleshooting.
<b>Log level</b>	Select <b>Debug</b> , <b>Info</b> , <b>Warning</b> or <b>Error</b> as the minimum severity level of message to log or select <b>None</b> to disable logging.
eDirectory Server List	
<b>Add</b>	Add an eDirectory server. See <a href="#">Adding an eDirectory server on page 532</a> .
<b>Delete</b>	Delete the selected eDirectory server.
<b>Edit</b>	Modify the settings for the selected server.
<b>Set Group Filters...</b>	Select the user groups whose user logons will be reported to the FortiGate unit. This is used only if user groups are not selected on the FortiGate unit.

## Adding an eDirectory server

Once the eDirectory agent is configured, you add one or more eDirectory servers.

### To add an eDirectory server:

1. In the eDirectory Agent Configuration Utility dialog box (see the preceding procedure, [Configuring the eDirectory agent](#)), select **Add**.
2. The eDirectory Setup dialog box opens. Enter the following information and select OK:

<b>eDirectory Server Address</b>	Enter the IP address of the eDirectory server.
<b>Port</b>	If the eDirectory server does not use the default port 389, clear the <b>Default</b> check box and enter the port number.
<b>Use default credential</b>	Select to use the credentials specified in the eDirectory Configuration Utility. See <a href="#">Configuring the eDirectory agent on page 530</a> . Otherwise, leave the check box clear and enter a username and Password below.
<b>User name</b>	Enter a username that has access to the eDirectory, using LDAP format.
<b>User password</b>	Enter the password.
<b>Use secure connection (SSL)</b>	Select to connect to the eDirectory server using SSL security.
<b>Search Base DN</b>	Enter the base Distinguished Name for the user search.

## Configuring a group filter

The eDirectory agent sends user logon information to the FortiGate unit for all user groups unless you either configure an LDAP server entry for the eDirectory on the FortiGate unit and select the groups that you want to monitor or configure the group filter on the eDirectory agent.

If both the FortiGate LDAP configuration and the eDirectory agent group filter are present, the FortiGate user group selections are used.

### To configure the group filter:

1. From the Start menu select **Programs > Fortinet > eDirectory Agent > eDirectory Config Utility**.
2. Select **Set Group Filters**.
3. Do one of the following:
  - Enter group names, then select **Add**.
  - Select **Advanced**, select groups, and then select **Add**.
4. Select **OK**.

## Configuring FSSO Advanced Settings

Depending on your network topologies and requirement, you may need to configure advanced settings in the FSSO Collector agent. To do so, from the Start menu, select **Programs > Fortinet > Fortinet Single Sign-On Agent > Configure Fortinet Single Sign-On Agent**, then from the **Common Tasks** section, select **Advanced Settings**.

This section include :

- [General Settings](#)
- [Citrix/Terminal Server](#)
- [Exchange Server](#)
- [RADIUS Accounting](#)

## General Settings

In the General tab, enter the following information and select **OK**.

<b>Worker thread count</b>	Number of threads started in the CA process. Default is 128 on CA version 5.0.0241.
<b>Maximum FortiGate connections</b>	Number of FortiGates can be connected to the CA. Default is 64.
<b>Group look-up interval</b>	The interval in seconds to lookup users/groups. If an AD group membership of currently logged on user, CA can detect this and update information on the FortiGate. Enter 0 for no checking.
<b>Windows security Event logs</b>	Choose the event logs to poll.
<b>Event IDs to poll</b>	0: Default set, it includes Kerberos authentication event logs : 672 for Windows server 2003, 4768 for Windows server 2008 and 2012 and NTLM authentication event logs : 680 for Windows server 2003, 4776 for Windows server 2008 and 2012. 1: Extended set, it includes Kerberos service ticket event logs : 673 for Windows server 2003, 4769 for Windows server 2008 and 2012. Service tickets are obtained whenever a user or computer accesses a server on the network. List the event ids separated by ",".
<b>Workstation Check</b>	Optionally enable <b>Use WMI to check user logoff</b> for the collector agent to query whether users is still logged on.
<b>Workstation Name Resolution Advance Options</b>	
<b>Alternative DNS server(s)</b>	Collector Agent uses the DNS server configured on the machine it is running on by default. If CA should use another DNS server then one or more alternative DNS server can be configured here.
<b>Alternative workstation suffix(es)</b>	If only host name is available CA uses the default domain suffix to build a FQDN for DNS queries. In case CA should use a different suffix, it can be configured as well.

**FSSO Collector Agent Advanced Settings**

General | **Citrix/Terminal Server** | Exchange Server | RADIUS Accounting

Worker thread count: 128

Maximum FortiGate connections: 64

Group lookup interval (in seconds): 0 (0 for no checking)

Windows Security Event Logs

Event IDs to poll: 0  
(0:default set, 1:extended set, or list the eventids separated by ';')

Workstation Check

☒ Use WMI to check user logoff

Workstation Name Resolution Advanced Options

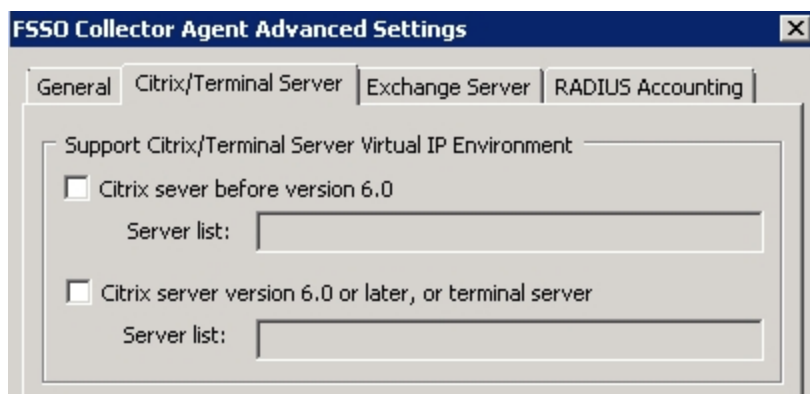

Alternative DNS server(s):

Alternative workstation suffix(es):

## Citrix/Terminal Server

In the Citrix/Terminal Server tab, enter the following information and select **OK**.

<b>Support Citrix/Terminal Server Virtual IP Environment</b>	When Citrix server are configured with VIP, CA can get user logon events from these server. Citrix changed their interface and data format so version of Citrix server is important.
<b>Citrix server before version 6.0</b>	Enable this option if you Citrix server version is before 6.0.
<b>Server list</b>	Enter the list of servers separated by colon.
<b>Citrix server version 6.0 or later, or Terminal Server</b>	Enable this option if you Citrix server version is 6.0 or later.
<b>Server list</b>	Enter the list of servers separated by colon.

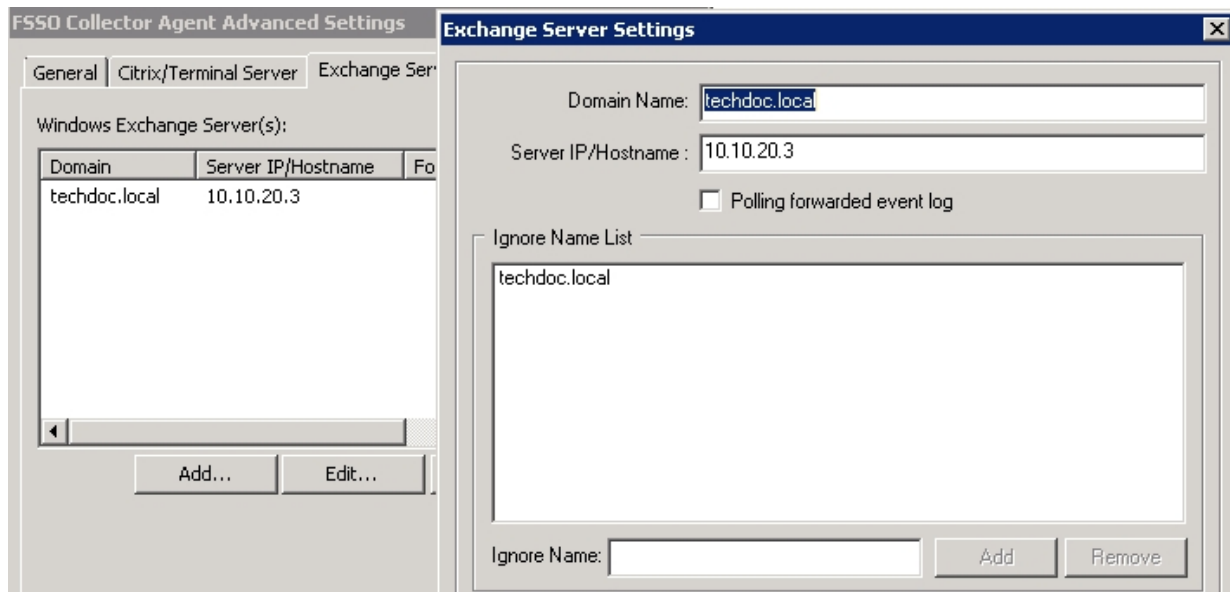

## Exchange Server

FSSO supports monitoring Microsoft Exchange Server. This is useful for situation that the user use the domain account to access their email, but client device might or might not be in the domain. Support for Exchange server is configured on the Back-end FSSO collector agent under **Advanced Settings > Exchange Server**.

Select **Add** and enter the following information and select **OK**.

<b>Domain Name</b>	Enter your domain name.
<b>Server IP/Hostname</b>	Enter the IP address or the hostname of your exchange server.
<b>Polling forwarded event log</b>	This option for scenarios when you do not want that CA polls the Exchange Server logs directly. In this case you need to configure event log forwarding on the Exchange server. Exchange event logs can be forwarded to any member server. If you enable this, instead of the IP of the Exchange server configured in the previous step, you must then configure the IP of this member server. CA will then contact the member server.
<b>Ignore Name</b>	Because CA will also check Windows log files for logon events and when a user authenticates to Exchange Server there is also a logon event in Windows event log, which CA will read and this will overwrite the Exchange Server logon event (ES-EventLog) on CA. So it is recommended to set the ignore list to the domain the user belongs to. To do so, enter the domain name in the <b>Ignore Name</b> field and select <b>Add</b> .

## RADIUS Accounting

A RADIUS server must be configured in your network to send accounting messages to the Collector Agent which can be configured to work with most RADIUS-based accounting systems. In most cases, you only need to do the following to your RADIUS accounting system:

- Add a user group name field to customer accounts on the RADIUS server so that the name is added to the RADIUS Start record sent by the accounting system to the Collector Agent. User group names do not need to be added for all users, only to the accounts of users who will use RADIUS Accounting feature on the Collector Agent.
- Configure your accounting system to send RADIUS Start records to the Collector Agent.

The Collector Agent should be configured to listen for RADIUS accounting messages as following.

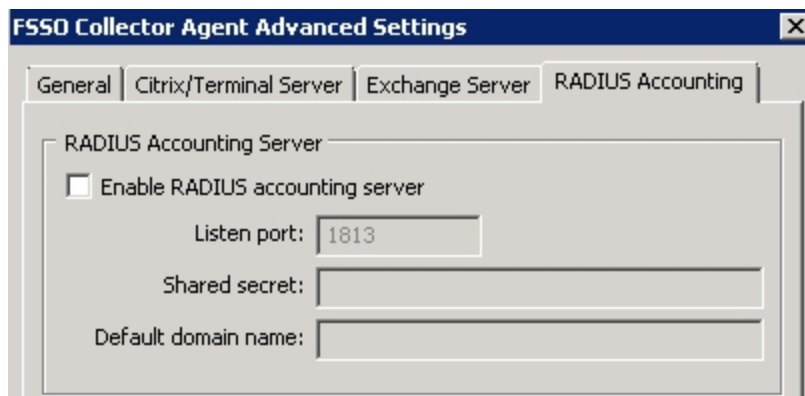

RADIUS Accounting Server	
<b>Enable RADIUS Accounting Server</b>	Enable this option to allow the CA to gather information about authenticated users via a RADIUS server and send these information to the FortiGate unit for monitoring.
<b>Listen port</b>	The port on which CA listens for RADIUS accounting messages. Default RADIUS accounting is 1813, but if RADIUS server sends accounting messages on different port, value can be configured here.
<b>Shared secret</b>	Common secret between CA and RADIUS server.

**Default domain name**

This should be the AD domain for which this CA is configured. In this case user name in RADIUS accounting message can be in simple format like user1.

If this value is empty, then user name in RADIUS accounting message must be in one of these formats user1@domain, Domain\user1 or domain/user1.

CA will use user name and domain to query group membership of user. Client IP address (Framed IP) should also be in RADIUS accounting message, so that CA can forward user name, IP address and groups to the FortiGate.

## Configuring FSSO on FortiGate units

To configure your FortiGate unit to operate with agent-based FSSO, you

- Configure any access to LDAP servers that might be necessary. Skip this step if you are using FSSO Standard mode. See [Configuring LDAP server access on page 537](#).
- Specify the Collector agent or Novell eDirectory agent that will provide user logon information. See [Specifying your Collector agents or Novell eDirectory agents on page 539](#).
- Add Active Directory user groups to FortiGate user groups. See [Creating Fortinet Single Sign-On \(FSSO\) user groups on page 540](#).
- Create security policies for FSSO-authenticated groups. See [Creating security policies on page 541](#).
- Optionally, specify a guest security policy to allow guest access. See [Enabling guest access through FSSO security policies on page 542](#).

### Configuring LDAP server access

LDAP access is required if your network has a Novell eDirectory agent or a Collector agent using Windows Advanced AD access mode. If you are using FSSO Standard mode, go to [Specifying your Collector agents or Novell eDirectory agents on page 539](#).

1. Go to **User & Device > LDAP Servers** and select **Create New**.
2. Enter the **Server IP/Name** and **Server Port** (default 389).
3. In the **Common Name Identifier** field, enter **sAMAccountName**. The default common name identifier is **cn**. This is correct for most LDAP servers. However some servers use other identifiers such as **uid**.

4. In the **Distinguished Name** field, enter your organization distinguished name. In this example, Distinguished Name is dc=techdoc,dc=local
5. Select **Fetch DN**, this will fetch the Windows AD directory.

Name: LDAP

Server IP/Name: 10.10.20.3

Server Port: 389

Common Name Identifier: sAMAccountName

Distinguished Name: dc=techdoc,dc=local

Bind Type: ☐ Simple ☐ Anonymous ☒ Regular

User DN:

Password:

☐ Secure Connection

Test

**LDAP Distinguished Name Query**

LDAP Tree

- dc=techdoc,dc=local
- CN=Computers
- CN=ForeignSecurityPrincipals
- CN=Managed Service Accounts
- CN=Program Data
- CN=System
- CN=Users
- OU=Domain Controllers

6. Set **Bind Type** to **Regular**.
7. In the **User DN** field, enter the administrative account name that you created for FSSO. For example, if the account is administrator, enter "administrator@techdoc.local".
8. Enter the administrative account password in the **Password** field.
9. Optionally select **Secure Connection**.
  - In the **Protocol** field, select **LDAPS** or **STARTTLS**.
  - In the **Certificate** field, select the appropriate certificate for authentication.

Note that you need to configure the Windows AD for secure connection accordingly.
10. Select **OK**.
11. Test your configuration by selecting the **Test** button. A successful message confirming the right settings appears.

Successful

Name: LDAP

Server IP/Name: 10.10.20.3

Server Port: 389

Common Name Identifier: sAMAccountName

Distinguished Name: dc=techdoc,dc=local

Fetch DN

Bind Type: ☐ Simple ☐ Anonymous ☒ Regular

User DN: administrator@techdoc.local

Password: .....

☐ Secure Connection

Test

**To configure LDAP for FSSO - CLI example:**

```

config user ldap
  edit LDAP
    set server 10.10.20.3
    set cnid sAMAccountName
    set dn dc=techdoc,dc=local
    set type regular
    set username administrator@techdoc.local
    set password <your_password>
  next
end

```

**Specifying your Collector agents or Novell eDirectory agents**

You need to configure the FortiGate unit to access at least one Collector agent or Novell eDirectory agent. You can specify up to five servers on which you have installed a Collector or eDirectory agent. The FortiGate unit accesses these servers in the order that they appear in the list. If a server becomes unavailable, the next one in the list is tried.

**To specify Collector agents - web-based manager:**

1. Go to **User & Device > Single Sign-On** and select **Create New**.
2. In **Type**, select **Fortinet Single-Sign-On Agent**.
3. Enter a **Name** for the Windows AD server. This name appears in the list of Windows AD servers when you create user groups.
4. Enter the following information for each of up to five collector agents and select **OK**:

<b>Agent IP/Name</b>	<p>Enter the IP address or the name of the server where this agent is installed. Maximum name length is 63 characters.</p> <p>If the TCP port used for FSSO is not the default, 8000, you can change the setting in the CLI using the <code>config user fssso</code> command.</p> <p>See <a href="#">Configuring Collector agent settings on page 518</a>.</p>
<b>Password</b>	<p>Enter the password for the Collector agent or eDirectory agent. For the Collector agent, this is required only if you configured the agent to require authenticated access.</p>

5. For Novell eDirectory or Windows AD with Collector agent in Advanced AD access mode select the **LDAP Server** you configured previously. See [Configuring LDAP server access on page 537](#).
6. In **Users/Groups**, select the **Users** or **Groups** or **Organizational Units** tab and then select the users or groups or OU that you want to monitor.
7. Select **OK**.

Name:   
 Primary Agent IP/Name:  Password:   
 Secondary Agent IP/Name:  Password:  [More FSSO agents](#)  
 LDAP Server:  X  
 Users/Groups:

LDAP Tree Recursive **ON**  
 dc=techdoc,dc=local

Add Selected
 

ID	Name	Full DN
Domain Controllers	Domain Controllers	CN=Domain Controllers,CN=Users,DC=techdoc,DC=local
Domain Guests	Domain Guests	CN=Domain Guests,CN=Users,DC=techdoc,DC=local
Domain Users	Domain Users	CN=Domain Users,CN=Users,DC=techdoc,DC=local
Enterprise Admins	Enterprise Admins	CN=Enterprise Admins,CN=Users,DC=techdoc,DC=local
Enterprise Read-only Domain Controllers	Enterprise Read-only Domain Controllers	CN=Enterprise Read-only Domain Controllers,CN=Users,DC=techdoc,DC=local
Event Log Readers	Event Log Readers	CN=Event Log Readers,CN=Builtin,DC=techdoc,DC=local
FortiOS Writers	FortiOS Writers	CN=FortiOS Writers,CN=Users,DC=techdoc,DC=local
Group Policy Creator Owners	Group Policy Creator Owners	CN=Group Policy Creator Owners,CN=Users,DC=techdoc,DC=local
Guests	Guests	CN=Guests,CN=Builtin,DC=techdoc,DC=local
IIS_IUSRS	IIS_IUSRS	CN=IIS_IUSRS,CN=Builtin,DC=techdoc,DC=local

### To specify the FSSO Collector agent - CLI:

In this example, the SSO server name is techdoc and the LDAP server is LDAP.

```
config user fsso
  edit techdoc
    set ldap-server LDAP
    set password <your_password>
    set server 10.10.20.3
    set port 8000
  end
```

### Creating Fortinet Single Sign-On (FSSO) user groups

You cannot use Windows or Novell groups directly in FortiGate security policies. You must create FortiGate user groups of the FSSO type and add Windows or Novell groups to them.

#### To create a user group for FSSO authentication - web-based manager:

1. Go to **User & Device > User Groups**.
2. Select **Create New**.  
The New User Group dialog box opens.
3. In the **Name** box, enter a name for the group, FSSO\_Internet\_users for example.
4. In **Type**, select **Fortinet Single Sign-On (FSSO)**.
5. In **Members**, select the required FSSO groups.
6. Select **OK**.

#### To create the FSSO\_Internet-users user group - CLI :

```
config user group
  edit FSSO_Internet_users
    set group-type fsso-service
    set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
    set member CN=Sales,cn=users,dc=office,dc=example,dc=com
  end
```

## Creating security policies

Policies that require FSSO authentication are very similar to other security policies. Using identity-based policies, you can configure access that depends on the FSSO user group. This allows each FSSO user group to have its own level of access to its own group of services.

In this situation, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate.

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fsso_group`, and the FSSO RADIUS server is `fsso_rad_server`.

### To configure an FSSO authentication security policy - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information.

<b>Incoming Interface</b>	port1
<b>Source Address</b>	company_network
<b>Source User(s)</b>	fsso_group
<b>Outgoing Interface</b>	port2
<b>Destination Address</b>	all
<b>Schedule</b>	always
<b>Service</b>	HTTP, HTTPS, FTP, and Telnet
<b>Action</b>	ACCEPT
<b>NAT</b>	ON
<b>UTM Security Profiles</b>	ON for AntiVirus, IPS, Web Filter, and Email Filter, all using default profiles.
<b>Log Allowed Traffic</b>	ON. Select <b>Security Events</b> .

3. Select **OK**.
4. Ensure the FSSO authentication policy is higher in the policy list than more general policies for the same interfaces.

### To create a security policy for FSSO authentication - CLI:

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr company_network
```

```
set dstaddr all
set action accept
set groups fsso_group
set schedule always
set service HTTP HTTPS FTP TELNET
set nat enable
end
```

Here is an example of how this FSSO authentication policy is used. Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet.

### Users belonging to multiple groups

Before FSSO 4.0 MR3, if a user belonged to multiple user groups, the first security policy to match any group that user belonged too was the only security policy applied. If that specific group did not have access to this protocol or resource where another group did, the user was still denied access. For example, `test_user` belongs to `group1` and `group2`. There are two FSSO authentication policies — one matches `group1` to authenticate FTP traffic and one matches `group2` to authenticate email traffic. The `group1` policy is at the top of the list of policies. If `test_user` wants to access an email server, the first policy encountered for a group `test_user` belongs to is the `group1` policy which does not allow email access and `test_user` is denied access. This is despite the next policy allowing access to email. If the order was reversed in this case, the traffic would be matched and the user's traffic would be allowed through the firewall. However if the policy order was reversed, FTP traffic would not be matched.

As of FSSO 4.0 MR3, if a user belongs to multiple groups multiple then attempts to match the group are attempted if applicable. Using the above example, when the attempt to match the `group1` policy is made and fails, the next policy with a group that `test_user` is a member of is attempted. In this case, the next policy is matched and access is granted to the email server.

When configuring this example the only difference between the policies is the services that are listed and the FSSO user group name.

Authenticating through multiple groups allows administrators to assign groups for specific services, and users who are members of each group have access to those services. For example there could be an FTP group, an email group, and a Telnet group.

### Enabling guest access through FSSO security policies

You can enable guest users to access FSSO security policies. Guests are users who are unknown to the Windows AD or Novell network and servers that do not logon to a Windows AD domain.

To enable guest access in your FSSO security policy, add an identity-based policy assigned to the built-in user group `SSO_Guest_Users`. Specify the services, schedule and protection profile that apply to guest users — typically guests receive reduced access to a reduced set of services.

### IPv6 support for FSSO

FortiGate FSSO supports connecting to an FSSO agent over IPv6 and collecting and sending IPv6 details about endpoints. This is enforced in the same manner as IPv4 FSSO traffic.

## Syntax

```
config user fsso
    edit <fsso agent name>
        set source-ip6 <IPv6 address for source>
    end
```

## FortiOS FSSO log messages

There are two types of FortiOS log messages — firewall and event. FSSO-related log messages are generated from authentication events. These include user logon and log off events, and NTLM authentication events. These log messages are central to network accounting policies, and can also be useful in troubleshooting issues. For more information on firewall logging, see "Enabling security logging". For more information on logging, see the FortiOS Handbook Log and Reporting guide.

### Enabling authentication event logging

For the FortiGate unit to log events, that specific type of event must be enabled under logging.

When VDOMs are enabled certain options may not be available, such as CPU and memory usage events. You can enable event logs only when you are logged on to a VDOM; you cannot enable event logs globally.

To ensure you log all the events need, set the minimum log level to Notification or Information. Firewall logging requires Notification as a minimum. The closer to Debug level, the more information will be logged. While this extra information is useful, you must

#### To enable event logging:

1. Go to **Log & Report > Log Settings**.
2. In **Event Logging**, select:

<b>System activity event</b>	All system-related events, such as ping server failure and gateway status.
<b>User activity event</b>	All administration events, such as user logins, resets, and configuration updates.

3. Optionally you can enable any or all of the other logging event options.
4. Select **Apply**.

### Authentication log messages

#	Date/Time	Level	Source	Action	Status	Message	Timestamp	
1	06:15:24		TELBAR (10.10.20.7)	FSSO-logout		FSSO-logout event from techdoc: user TELBAR logged off 10.10.20.7	11/12/2015, 6:15:24 AM	⚙
2	11-11 22:22		ADMINISTRATOR (10.10.20.3)	authentication	logout	User ADMINISTRATOR succeeded in logout	11/11/2015, 10:22:15 P	
3	11-11 22:22		ADMINISTRATOR (10.10.20.3)	FSSO-logout		FSSO-logout event from techdoc: user ADMINISTRATOR logged off 10.10.20.3	11/11/2015, 10:22:15 P	
4	11-11 22:17		ADMINISTRATOR (10.10.20.3)	FSSO-logon		FSSO-logon event from techdoc: user ADMINISTRATOR logged on 10.10.20.3	11/11/2015, 10:17:12 P	

< 1 / 5 [ Total: 246 ] >

#	1	Action	FSSO-logout
Date/Time	06:15:24	Dst	techdoc
Level		Log Description	FSSO logout authentication status
Log ID	43015	Message	FSSO-logout event from techdoc: user TELBAR logged off 10.10.20.7
Source	TELBAR (10.10.20.7)	Sub Type	user
Timestamp	11/12/2015, 6:15:24 AM	User	TELBAR
Virtual Domain	root		

## List of FSSO related log messages

Message ID	Severity	Description
43008	Notification	Authentication was successful
43009	Notification	Authentication session failed
43010	Warning	Authentication locked out
43011	Notification	Authentication timed out
43012	Notification	FSSO authentication was successful
43013	Notification	FSSO authentication failed
43014	Notification	FSSO user logged on
43015	Notification	FSSO user logged off
43016	Notification	NTLM authentication was successful
43017	Notification	NTLM authentication failed

For more information on logging, see the FortiOS Handbook Log and Reporting guide.

## Using filters

Logon events are detected by the FSSO CA by monitoring the Security Event logs. Additional logon event filters, such as ServiceName and ServiceID, have been implemented so as to avoid instances of conflicting security events, where existing FSSO logon user information could be overwritten and impact user connectivity.

The problem arises when a scenario such as the following occurs:

1. **User1** logs on to **PC1** on 1.1.1.1, which is logged as a successful Kerberos logon event with an ID of 4769.
2. The FortiGate creates an authenticated FSSO user log entry for **User1/1.1.1.1**.
3. **User1** then maps a network drive and uses credentials for **User2** to logon to the same PC (**PC1**).
4. The FortiGate sees this as a separate logon to **PC1** by a new user, **User2**. As a result, the log entry is updated to **User2/1.1.1.1**.
5. If **User2** is a member of a different user group to **User1** (i.e. has different access permissions), **User1** could lose access to their network resources.

The new filter makes the CA ignore the event log created when **User1** mapped a network drive, meaning that the original entry for **User1** will not be changed.

While this is a useful feature, it is highly recommended to test filters in a redundant test environment.

## Testing FSSO

Once FSSO is configured, you can easily test to ensure your configuration is working as expected. For additional FSSO testing, see [Troubleshooting FSSO on page 545](#).

1. Logon to one of the stations on the FSSO domain, and access an Internet resource.
2. Connect to the CLI of the FortiGate unit, and if possible log the output.
3. Enter the following command:

```
diagnose debug authd fsso list
```

4. Check the output. If FSSO is functioning properly you will see something similar to the following:

```
----FSSO logons----
IP: 10.10.20.3 User: ADMINISTRATOR Groups: CN=FORTIOS WRITERS,CN=USERS,DC=TECHDOC,DC=LOCAL
Workstation: WIN2K8R2.TECHDOC.LOCAL MemberOf: FortiOS_Writers
IP: 10.10.20.7 User: TELBAR Groups: CN=FORTIOS WRITERS,CN=USERS,DC=TECHDOC,DC=LOCAL
Workstation: TELBAR-PC7.TECHDOC.LOCAL
Total number of logons listed: 2, filtered: 0
----end of FSSO logons----
```

The exact information will vary based on your installation.

5. Check the FortiGate event log, for FSSO-auth action or other FSSO related events with FSSO information in the message field.
6. To check server connectivity, run the following commands from the CLI:

```
FGT# diagnose debug enable
FGT# diagnose debug authd fsso server-status
FGT# Server Name Connection Status Version
-----
techdoc          connected FSSO 5.0.0241
```

## Troubleshooting FSSO

When installing, configuring, and working with FSSO some problems are quite common. A selection of these problems follows including explanations and solutions.

Some common Windows AD problems include:

- [General troubleshooting tips for FSSO](#)
- [Users on a particular computer \(IP address\) cannot access the network](#)
- [Guest users do not have access to network](#)
- [Can't find the DCagent service](#)
- [User logon events not received by FSSO Collector agent](#)
- [Mac OS X users can't access external resources after waking from sleep mode](#)

### General troubleshooting tips for FSSO

The following tips are useful in many FSSO troubleshooting situations.

- Ensure all firewalls are allowing the FSSO required ports through.  
FSSO has a number of required ports that must be allowed through all firewalls or connections will fail. These include: ports 139, 389 (LDAP), 445, 636 (LDAP) 8000, and 8002.
- Ensure the Collector agent has at least 64kbps bandwidth to the FortiGate unit.  
If not the Collector agent does not have this amount of bandwidth, information FSSO information may not reach

the FortiGate unit resulting in outages. The best solution is to configure traffic shaping between the FortiGate unit and the Collector agent to ensure that minimum bandwidth is always available.

### Users on a particular computer (IP address) cannot access the network

Windows AD Domain Controller agent gets the username and workstation where the logon attempt is coming from. If there are two computers with the same IP address and the same user trying to logon, it is possible for the authentication system to become confused and believe that the user on computer\_1 is actually trying to access computer\_2.

Windows AD does not track when a user logs out. It is possible that a user logs out on one computer, and immediately logs onto a second computer while the system still believes the user is logged on the original computer. While this is allowed, information that is intended for the session on one computer may mistakenly end up going to the other computer instead. The result would look similar to a hijacked session.

### Solutions

- Ensure each computer has separate IP addresses.
- Encourage users to logout on one machine before logging onto another machine.
- If multiple users have the same username, change the usernames to be unique.
- Shorten timeout timer to flush inactive sessions after a shorter time.

### Guest users do not have access to network

A group of guest users was created, but they don't have access.

### Solution

The group of the guest users was not included in a policy, so they do not fall under the guest account. To give them access, associate their group with a security policy.

Additionally, there is a default group called `SSO_Guest_Users`. Ensure that group is part of an identity-based security policy to allow traffic.

### Can't find the DCagent service

The DCagent service can't be found in the list of regular windows services. This is because it has no associated Windows service.

Instead DCagent is really `dcagent.dll` and is located in the `Windows\system32` folder. This DLL file is loaded when windows boots up and it intercepts all logon events processed by the domain controller to send these events to the Collector agent (CA).

### Solution

#### To verify that the DCagent is installed properly

1. Check that `DCagent.dll` exists in `Windows\system32` folder.
2. Check that the registry key exists: `[HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\dcagent]`

If both exist, the DCagent is properly installed.

### User logon events not received by FSSO Collector agent

When a warning dialog is present on the screen on the Collector agent computer, the Collector agent will not receive any logon events. Once the dialog has been closed normal operation will resume.

If polling mode is enabled, it is possible the polling interval is too large. Use a shorter polling interval to ensure the collector agent is capturing all logon events.

The polling interval can only be adjusted using the firewall-embedded agent itself, not on agents deployed to member servers.

---

If NetAPI polling mode is enabled, consider switching to Event logs or Event Logs using WMI polling as it provides better accuracy.

### Mac OS X users can't access external resources after waking from sleep mode

When client computers running Mac OS X (10.6.X and higher) wake up from sleep mode, the user must authenticate again to be able to access external resources. If the user does not re-authenticate, the user will maintain access to internal web sites, but will be unable to access any external resources.

This issue is caused by Mac OS X not providing sufficient information to the FSSO. This results in the FortiGate blocking access to the user because they cannot be authenticated.

#### Solution

The security settings on client computer(s) must be configured to require that a username and password be entered when exiting sleep mode or screen saver. With this feature enabled in Mac OS X, the FortiGate will receive the authentication information it requires to authenticate the user and allow them access.

Note that if the user reverts their settings to disable the password requirement, this will cause the issue to reappear.

## SSO using RADIUS accounting records

A FortiGate unit can authenticate users transparently who have already authenticated on an external RADIUS server. Based on the user group to which the user belongs, the security policy applies the appropriate UTM profiles. RADIUS SSO is relatively simple because the FortiGate unit does not interact with the RADIUS server, it only monitors RADIUS accounting records that the server forwards (originating from the RADIUS client). These records include the user's IP address and user group.

After the initial set-up, changes to the user database, including changes to user group memberships, are made on the external RADIUS server, not on the FortiGate unit.

This section describes:

- [User's view of RADIUS SSO authentication](#)
- [Configuration Overview](#)
- [Configuring the RADIUS server](#)
- [Creating the FortiGate RADIUS SSO agent](#)
- [Defining local user groups for RADIUS SSO](#)
- [Creating security policies](#)
- [Example: webfiltering for student and teacher accounts](#)

### User's view of RADIUS SSO authentication

For the user, RADIUS SSO authentication is simple:

- The user connects to the RADIUS server and authenticates.
- The user attempts to connect to a network resource that is reached through a FortiGate unit. Authentication is required for access, but the user connects to the destination without being asked for logon credentials because the FortiGate unit knows that the user is already authenticated. FortiOS applies UTM features appropriate to the user groups that the user belongs to.

### Configuration Overview

The general steps to implement RADIUS Single Sign-On are:

1. If necessary, configure your RADIUS server. The user database needs to include user group information and the server needs to send accounting messages.
2. Create the FortiGate RADIUS SSO agent.
3. Define local user groups that map to RADIUS groups.
4. Create a security policy which specifies the user groups that are permitted access.

### Configuring the RADIUS server

You can configure FortiGate RSSO to work with most RADIUS-based accounting systems. In most cases, you only need to do the following to your RADIUS accounting system:

- Add a user group name field to customer accounts on the RADIUS server so that the name is added to the RADIUS Start record sent by the accounting system to the FortiOS unit. User group names do not need to be added for all

users, only to the accounts of users who will use RSSO feature on the FortiGate unit.

- Configure your accounting system to send RADIUS Start records to the FortiOS unit. You can send the RADIUS Start records to any FortiGate network interface. If your FortiGate unit is operating with virtual domains (VDOMs) enabled, the RADIUS Start records must be sent to a network interface in the management VDOM.

## IPv6 RADIUS Support

RADIUS authentication is supported with IPv6, allowing administrators to configure an IPv6 RADIUS server on the FortiGate for IPv6 RADIUS authentication traffic to pass between the server and FortiGate.

Note that while you can set the primary RADIUS server's IPv6 address, the source IP address for communications to the RADIUS server cannot be configured as IPv6.

---

### Syntax

Allow IPv6 access on an interface:

```
config system interface
  edit <name>
    config ipv6
      set ip6-allowaccess {ping | https | ssh | snmp | http | telnet | fgfm | capwap}
      set ip6-address <xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx/xxx>
    next
  next
end
```

Configure the IPv6 RADIUS server:

```
config user radius
  edit <name>
    set server <xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx>
    ...
  next
end
```

## Creating the FortiGate RADIUS SSO agent

Once you define a RADIUS SSO (RSSO) agent, the FortiGate unit will accept user logon information from any RADIUS server that has the same shared secret. You can create only one RSSO agent in each VDOM.

Before you create the RSSO agent, you need to allow RADIUS accounting information on the interface that connects to the RADIUS server.

### To enable RADIUS access on the interface - web-based manager:

1. Go to **Network > Interfaces** and edit the interface to which the RADIUS server connected.
2. Select **Listen for RADIUS Accounting Messages**.
3. Select **OK**.

### To enable RADIUS access on the interface - CLI:

In this example, the port2 interface is used.

```
config system interface
  edit port2
    set allowaccess radius-acct
  end
```

#### To create a RADIUS SSO agent:

1. Go to **User & Device > Single Sign-On** and select **Create New**.
2. In **Type**, select **RADIUS Single-Sign-On Agent**.
3. Select **Use RADIUS Shared Secret** and enter the RADIUS server shared secret.
4. Select **Send RADIUS Responses**.
5. Select **OK**.

#### To create a RADIUS SSO agent - CLI

```
config user radius
  edit RSSO_Agent
    set rso enable
    set rso-validate-request-secret enable
    set rso-secret <your secret>
    set rso-radius-response enable
  end
```

### Selecting which RADIUS attributes are used for RSSO

For RADIUS SSO to work, FortiOS needs to know the user's endpoint identifier (usually IP address) and RADIUS user group. There are default RADIUS attributes where FortiOS expects this information, but you can change these attributes in the `config user radius` CLI command.

#### RSSO information and RADIUS attribute defaults

RSSO Information	RADIUS Attribute	CLI field
Endpoint user IP	Framed-IP-Address	<code>rso-endpoint-attribute</code>
Endpoint identifier	Calling-Station-ID	<code>rso-endpoint-attribute</code>
Endpoint block attribute	Called-Station-ID	<code>rso-endpoint-block-attribute</code>
User group	Class	<code>sso-attribute</code>
User	Prefix	<code>delegated-IPv6-prefix</code>
User	Prefix	<code>framed-IPv6-prefix</code>

The Endpoint block attribute can be used to block or allow a user. If the attribute value is set to the name of an attribute that indicates whether to block or allow, FortiOS blocks or allows respectively all traffic from that user's IP address. The RSSO fields are visible only when `rso` is set to `enable`.

The Prefix attributes allow for RSSO to provide a /56 prefix for DSL customers. All devices connected from the same location (/56 per subscriber) can be mapped to the same profile without the need to create multiple /64 or smaller entries.

### Override SSO attribute

Prior to FortiOS 5.4, when receiving a new start message with a different group name for the same user, and a different IP address such as for a roaming mobile device, the original process was to override all group name information to the latest group name received from the latest start message.

You can disable this override when needed. The default behavior keeps the original design.

#### To enable or disable overriding SSO attribute - CLI

```
config user radius
edit <name>
set rso <enable>
set sso-attribute-value-override {enable | disable} Enable/disable override of old attribute value with new value for the same endpoint.
```

### Configuring logging for RSSO

In the `config user radius` CLI command, you can set the following flags in the `rso-log-flags` field to determine which types of RSSO-related events are logged:

- `protocol-error` — A RADIUS protocol error occurred.
- `profile-missing` — FortiOS cannot find a user group name in a RADIUS start message that matches the name of an RSSO user group in FortiOS.
- `accounting-stop-missed` — a user context entry expired without FortiOS receiving a RADIUS Stop message.
- `accounting-event` — FortiOS did not find the expected information in a RADIUS record.
- `endpoint-block` — FortiOS blocked a user because the RADIUS record's endpoint block attribute had the value "Block".
- `radiusd-other` — Other events, described in the log message.

## Defining local user groups for RADIUS SSO

You cannot use RADIUS user groups directly in security policies. Instead, you create locally-defined user groups on the FortiGate unit and associate each of them with a RADIUS user group.

#### To define local user groups for RADIUS SSO:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a Name for the user group.
3. In **Type**, select **RADIUS Single Sign-On (RSSO)**.
4. In **RADIUS Attribute Value**, enter the name of the RADIUS user group this local user group represents.
5. Select **OK**.

#### To define local user groups for RADIUS SSO:

This example creates an RSSO user group called RSSO-1 that is associated with RADIUS user group "student".

```
config user group
edit RSSO-1
```

```

set group-type rsso
set sso-attribute-value student
end

```

## Creating security policies

RADIUS SSO uses regular identity-based security policies. The RSSO user group you specify determines which users are permitted to use the policy. You can create multiple policies if user groups can have different UTM features enabled, different permitted services, schedules, and so on.

### To create a security policy for RSSO - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Enter the following information.

<b>Incoming Interface</b>	as needed
<b>Source Address</b>	as needed
<b>Source User(s)</b>	Select the user groups you created for RSSO. See <a href="#">Defining local user groups for RADIUS SSO on page 551</a> .
<b>Outgoing Interface</b>	as needed
<b>Destination Address</b>	all
<b>Schedule</b>	as needed
<b>Service</b>	as needed
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Selected
<b>Security Profiles</b>	Select security profiles appropriate for the user group.

4. Select **OK**.

To ensure an RSSO-related policy is matched first, the policy should be placed higher in the security policy list than more general policies for the same interfaces.

5. Select **OK**.

### To create a security policy for RSSO - CLI:

In this example, an internal network to Internet policy enables web access for members of a student group and activates the appropriate UTM profiles.

```

config firewall policy
edit 0
set srcintf internal
set dstintf wan1
set srcaddr all
set dstaddr "all"

```

```
set action accept
set rso enable
set groups "RSSO-student"
set schedule always
set service HTTP HTTPS
set nat enable
set utm-status enable
set av-profile students
set webfilter-profile students
set spamfilter-profile students
set dlp-sensor default
set ips-sensor default
set application-list students
set profile-protocol-options "default"
end
```

## Example: webfiltering for student and teacher accounts

The following example uses RADIUS SSO to apply web filtering to students, but not to teachers. Assume that the RADIUS server is already configured to send RADIUS Start and Stop records to the FortiGate unit. There are two RADIUS user groups, **students** and **teachers**, recorded in the default attribute **Class**. The workstations are connected to port1, port2 connects to the RADIUS server, and port3 connects to the Internet.

### Configure the student web filter profile:

1. Go to **Security Profiles > Web Filter** and select **Create New** (the “+” button).
2. Enter the following and select **OK**.

<b>Name</b>	student
<b>Inspection Mode</b>	Proxy
<b>FortiGuard Categories</b>	Enable. Right-click the <b>Potentially Liable</b> category and select <b>Block</b> . Repeat for <b>Adult/Mature Content</b> and <b>Security Risk</b> .

### Create the RADIUS SSO agent:

1. Go to **User & Device > Single Sign-On** and select **Create New**.
2. In **Type**, select **RADIUS Single-Sign-On**.
3. Select **Use RADIUS Shared Secret** and enter the RADIUS server shared secret.
4. Select **Send RADIUS Responses**.
5. Select **OK**.

### Define local user groups associated with the RADIUS SSO user groups:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following and select **OK**.

<b>Name</b>	RSSO-students
-------------	---------------

<b>Type</b>	RADIUS Single Sign-On (RSSO)
<b>RADIUS Attribute Value</b>	students

3. Select **Create New**, enter the following and select **OK**.

<b>Name</b>	RSSO-teachers
<b>Type</b>	RADIUS Single Sign-On (RSSO)
<b>RADIUS Attribute Value</b>	teachers

#### Create a security policy for students:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter

<b>Incoming Interface</b>	port1
<b>Source Address</b>	all
<b>Source User(s)</b>	RSSO-students
<b>Source Device Type</b>	All
<b>Outgoing Interface</b>	port3
<b>Destination Address</b>	all
<b>Schedule</b>	always
<b>Service</b>	HTTP, HTTPS
<b>Action</b>	ACCEPT
<b>NAT</b>	ON
<b>Security Profiles</b>	Enable AntiVirus, Web Filter, IPS.  In Web Filter, select the <b>student</b> profile.

3. Select **OK**.

#### Create a security policy for teachers:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter

<b>Incoming Interface</b>	port2
<b>Source Address</b>	all

<b>Source User(s)</b>	RSSO-teachers
<b>Source Device Type</b>	All
<b>Outgoing Interface</b>	port3
<b>Destination Address</b>	all
<b>Schedule</b>	always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT
<b>NAT</b>	ON
<b>Security Profiles</b>	Enable AntiVirus and IPS.

3. Select **OK**.

## Monitoring authenticated users

This section describes how to view lists of currently logged-in firewall and VPN users. It also describes how to disconnect users.

The following topics are included in this section:

- [Monitoring firewall users](#)
- [Monitoring SSL VPN users](#)
- [Monitoring IPsec VPN users](#)
- [Monitoring users Quarantine](#)

## Monitoring firewall users

To monitor firewall users, go to **Monitor > Firewall User Monitor**.

Refresh De-authenticate

User Name	User Group	Policy ID	Duration	IP Address	Traffic Volume	Method	
user3	Group1	2	0 day(s) 0 hour(s) 4 minute(s)	10.11.101.20	35 KB	FW-auth	
user4	Group1	2	0 day(s) 3 hour(s) 4 minute(s)	10.11.101.101	421 KB	FW-auth	

You can de-authenticate a user by selecting the Delete icon for that entry.

You can filter the list of displayed users by selecting the funnel icon for one of the column titles or selecting **Filter Settings**.

Optionally, you can de-authenticate multiple users by selecting them and then selecting **De-authenticate**.

## Monitoring SSL VPN users

You can monitor web-mode and tunnel-mode SSL VPN users by username and IP address.

To monitor SSL VPN users, go to **Monitor > SSL-VPN Monitor**. To disconnect a user, select the user and then select the **Delete** icon.

<div> Delete</div>					
<input type="checkbox"/>	No.	User	Source IP	Begin Time	Description
<input type="checkbox"/>	1	user2	172.20.120.51	Wed Mar 17 13:17:32 2010	
<input checked="" type="checkbox"/>		Subsession			Tunnel IP:10.0.0.1

The first line, listing the username and IP address, is present for a user with either a web-mode or tunnel-mode connection. The Subsession line is present only if the user has a tunnel mode connection. The **Description** column displays the virtual IP address assigned to the user's tunnel-mode connection.

For more information about SSL VPN, see the FortiOS Handbook SSL VPN guide.

### To monitor SSL VPN users - CLI:

To list all of the SSL VPN sessions and their index numbers:

```
execute vpn sslvpn list
```

The output looks like this:

```
SSL-VPN Login Users:
  Index   User   Auth Type   Timeout   From           HTTPS in/out
  0       user1  1           256       172.20.120.51  0/0

SSL-VPN sessions:
  Index   User   Source IP       Tunnel/Dest IP
  0       user2  172.20.120.51   10.0.0.1
```

You can use the Index value in the following commands to disconnect user sessions:

#### To disconnect a tunnel-mode user

```
execute vpn sslvpn del-tunnel <index>
```

#### To disconnect a web-mode user

```
execute vpn sslvpn del-web <index>
```

You can also disconnect multiple users:

#### To disconnect all tunnel-mode SSL VPN users in this VDOM

```
execute vpn ssl del-all tunnel
```

#### To disconnect all SSL VPN users in this VDOM

```
execute vpn ssl del-all
```

## Monitoring IPsec VPN users

To monitor IPsec VPN tunnels in the web-based manager, go to **Monitor > IPsec Monitor**. user names are available only for users who authenticate with XAuth.

You can close a tunnel by selecting the tunnel and right click to select **Bring Down**.

Type	Name	Remote Gateway	Timeout	Status	Incoming Data	Outgoing Data	Username
Dialup	dialup1_0	172.20.120.51	1116	Bring Down	79233170 B	171639314 B	user2

For more information, see the FortiOS Handbook IPsec VPN guide.

## Monitoring users Quarantine

The User Quarantine list shows all IP addresses and interfaces blocked by NAC quarantine. The list also shows all IP addresses, authenticated users, senders, and interfaces blocked by Data Leak Prevention (DLP). The system administrator can selectively release users or interfaces from quarantine or configure quarantine to expire after a selected time period.

All sessions started by users or IP addresses on the User Quarantine list are blocked until the user or IP address is removed from the list. All sessions to an interface on the list are blocked until the interface is removed from the list.

You can configure NAC quarantine to add users or IP addresses to the User Quarantine list under the following conditions:

- **Users or IP addresses that originate attacks detected by IPS** - To quarantine users or IP addresses that originate attacks, enable and configure **Quarantine** in an IPS Filter.
- **Users or IP addresses that are quarantined by Data Leak Prevention** - In a DLP sensor select **Quarantine IP Address** as the action to take.

For more information, see FortiOS Handbook Security Profiles guide.

Users are viewed from **Monitor > Quarantine Monitor**.

<b>Delete</b>	Removes the selected user or IP address from the User Quarantine list.
<b>Remove All</b>	Removes all users and IP addresses from the User Quarantine list.
<b>Search</b>	Search the list for a particular IP address.
<b>Source</b>	The FortiGate function that caused the user or IP address to be added to the User Quarantine list: IPS or Data Leak Prevention.
<b>Created</b>	The date and time the user or IP address was added to the Banned User list.
<b>Expires</b>	The date and time the user or IP address will be automatically removed from the User Quarantine list. If <b>Expires</b> is <b>Indefinite</b> , you must manually remove the user or host from the list.

## Examples and Troubleshooting

This chapter provides an example of a FortiGate unit providing authenticated access to the Internet for both Windows network users and local users.

The following topics are included in this section:

- [Firewall authentication example](#)
- [LDAP Dial-in using member-attribute example](#)
- [RADIUS SSO example](#)
- [Troubleshooting](#)

### Firewall authentication example

#### Example configuration

#### Overview

In this example, there is a Windows network connected to Port 2 on the FortiGate unit and another LAN, Network\_1, connected to Port 3.

All Windows network users authenticate when they logon to their network. Members of the Engineering and Sales groups can access the Internet without entering their authentication credentials again. The example assumes that the Fortinet Single Sign On (FSSO) has already been installed and configured on the domain controller.

LAN users who belong to the Internet\_users group can access the Internet after entering their username and password to authenticate. This example shows only two users, User1 is authenticated by a password stored on the FortiGate unit, User2 is authenticated on an external authentication server. Both of these users are referred to as local users because the user account is created on the FortiGate unit.

#### Creating a locally-authenticated user account

User1 is authenticated by a password stored on the FortiGate unit. It is very simple to create this type of account.

**To create a local user - web-based manager:**

1. Go to **User & Device > User Definition** and select **Create New**.
2. Follow the User Creation Wizard, entering the following information and then select **Create**:

<b>User Type</b>	Local User
<b>User Name</b>	User1
<b>Password</b>	hardtoguess
<b>Email Address SMS</b>	(optional)
<b>Enable</b>	Select.

**To create a local user - CLI:**

```
config user local
  edit user1
    set type password
    set passwd hardtoguess
  end
```

**Creating a RADIUS-authenticated user account**

To authenticate users using an external authentication server, you must first configure the FortiGate unit to access the server.

**To configure the remote authentication server - web-based manager:**

1. Go to **User & Device > RADIUS Servers** and select **Create New**.
2. Enter the following information and select **OK**:

<b>Name</b>	OurRADIUSsrv
<b>Primary Server Name/IP</b>	10.11.101.15
<b>Primary Server Secret</b>	OurSecret
<b>Authentication Scheme</b>	Select <b>Use Default Authentication Scheme</b> .

**To configure the remote authentication server - CLI:**

```
config user radius
  edit OurRADIUSsrv
    set server 10.11.102.15
    set secret OurSecret
    set auth-type auto
  end
```

Creation of the user account is similar to the locally-authenticated account, except that you specify the RADIUS authentication server instead of the user's password.

**To configure a remote user - web-based manager:**

1. Go to **User & Device > User Definition** and select **Create New**.
2. Follow the User Creation Wizard, entering the following information and then select **Create**:

<b>User Type</b>	Remote RADIUS User
<b>User Name</b>	User2
<b>RADIUS server</b>	OurRADIUSsrv
<b>Email Address SMS</b>	(optional)
<b>Enable</b>	Select

**To configure a remote user - CLI:**

```
config user local
edit User2
set name User2
set type radius
set radius-server OurRADIUSsrv
end
```

**Creating user groups**

There are two user groups: an FSSO user group for FSSO users and a firewall user group for other users. It is not possible to combine these two types of users in the same user group.

**Creating the FSSO user group**

For this example, assume that FSSO has already been set up on the Windows network and that it uses Advanced mode, meaning that it uses LDAP to access user group information. You need to

- configure LDAP access to the Windows AD global catalog
- specify the collector agent that sends user logon information to the FortiGate unit
- select Windows user groups to monitor
- select and add the Engineering and Sales groups to an FSSO user group

**To configure LDAP for FSSO - web-based manager:**

1. Go to **User & Device > LDAP Servers** and select **Create New**.
2. Enter the following information:

<b>Name</b>	ADserver
<b>Server Name / IP</b>	10.11.101.160
<b>Distinguished Name</b>	dc=office,dc=example,dc=com
<b>Bind Type</b>	Regular

<b>User DN</b>	cn=FSSO_Admin,cn=users,dc=office,dc=example,dc=com
<b>Password</b>	set_a_secure_password

3. Leave other fields at their default values.
4. Select **OK**.

### To configure LDAP for FSSO - CLI"

```
config user ldap
  edit "ADserver"
    set server "10.11.101.160"
    set dn "cn=users,dc=office,dc=example,dc=com"
    set type regular
    set username "cn=admin,dc=office,dc=example,dc=com"
    set password set_a_secure_password
  next
end
```

### To specify the collector agent for FSSO - web-based manager

1. Go to **User & Device > Single Sign-On** and select **Create New**.
2. Enter the following information:

<b>Type</b>	Fortinet Single Sign-On Agent
<b>Name</b>	WinGroups
<b>Primary Agent IP/Name</b>	10.11.101.160
<b>Password</b>	fortinet_canada
<b>LDAP Server</b>	ADserver

3. Select **Apply & Refresh**.

In a few minutes, the FortiGate unit downloads the list of user groups from the server.

### To specify the collector agent for FSSO - CLI:

```
config user fsso
  edit "WinGroups"
    set ldap-server "ADserver"
    set password ENC
      G7GQV7NEqilCM9jKmVmJJFVvhQ2+wtNEe9T0iYA5Sa+EQT2J8zhOrbkJFDr0RmY3c4LaoXdsoBczA
      1dONmcGfthTxxwGsigzGpbJdC7lspFlQYtj
    set server "10.11.101.160"
  end
```

### To create the FSSO\_Internet-users user group - web-based manager:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

<b>Name</b>	FSSO_Internet_users
<b>Type</b>	Fortinet Single Sign-On (FSSO)
<b>Members</b>	Engineering, Sales

**To create the FSSO\_Internet-users user group - CLI:**

```
config user group
  edit FSSO_Internet_users
    set group-type fsso-service
    set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
      CN=Sales,cn=users,dc=office,dc=example,dc=com
  end
```

**Creating the Firewall user group**

The non-FSSO users need a user group too. In this example, only two users are shown, but additional members can be added easily.

**To create the firewall user group - web-based manager:**

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter the following information and then select **OK**:

<b>Name</b>	Internet_users
<b>Type</b>	Firewall
<b>Members</b>	User1, User2

**To create the firewall user group - CLI:**

```
config user group
  edit Internet_users
    set group-type firewall
    set member User1 User2
  end
```

**Defining policy addresses**

1. Go to **Policy & Objects > Addresses**.
2. Create the following addresses:

<b>Address Name</b>	Internal_net
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	10.11.102.0/24
<b>Interface</b>	Port 3

<b>Address Name</b>	Windows_net
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	10.11.101.0/24
<b>Interface</b>	Port 2

## Creating security policies

Two security policies are needed: one for firewall group who connect through port3 and one for FSSO group who connect through port2.

### To create a security policy for FSSO authentication - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information:

<b>Incoming Interface</b>	Port2
<b>Source Address</b>	Windows_net
<b>Source User(s)</b>	FSSO_Internet_users
<b>Outgoing Interface</b>	Port1
<b>Destination Address</b>	all
<b>Schedule</b>	always
<b>Service</b>	ALL
<b>NAT</b>	ON
<b>Security Profiles</b>	Optionally, enable security profiles.

3. Select OK.

### To create a security policy for FSSO authentication - CLI:

```
config firewall policy
edit 0
set srcintf port2
set dstintf port1
set srcaddr Windows_net
set dstaddr all
set action accept
set groups FSSO_Internet_users
set schedule always
set service ANY
set nat enable
end
```

**To create a security policy for local user authentication - web-based manager**

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information:

<b>Incoming Interface</b>	Port3
<b>Source Address</b>	Internal_net
<b>Source User(s)</b>	Internet_users
<b>Outgoing Interface</b>	Port1
<b>Destination Address</b>	all
<b>Schedule</b>	always
<b>Service</b>	ALL
<b>NAT</b>	ON
<b>Security Profiles</b>	Optionally, enable security profiles.

3. Select **OK**.

**To create a security policy for local user authentication - CLI**

```
config firewall policy
  edit 0
    set srcintf port3
    set dstintf port1
    set srcaddr internal_net
    set dstaddr all
    set action accept
    set schedule always
    set groups Internet_users
    set service ANY
    set nat enable
  end
```

**LDAP Dial-in using member-attribute example**

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to set up a VPN connection simply based on an attribute that is set to TRUE, instead of based on their user group. In AD the "Allow Dialin" property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to "TRUE".

This same procedure can be used for other member attributes, as your system requires.

To accomplish this with a FortiGate unit, member-attribute must be set. This can only be accomplished through the CLI - the option is not available through the web-based manager.

Before configuring the FortiGate unit, ensure the AD server has the `msNPAllowDialin` attribute set to "TRUE" for the users in question. If not, those users will not be able to authenticate.

**To configure user LDAP member-attribute settings - CLI:**

```

config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
    set cnid "sAMAccountName"
    set dn "DC=fortilabanz,DC=com,DC=au"
    set type regular
    set username "fortigate@sample.com"
    set password *****
    set member-attr "msNPAllowDialin"
  next
end

```

**To configure LDAP group settings - CLI:**

```

config user group
  edit "ldap_grp"
    set member "ldap"
    config match
      edit 1
        set server-name "ldap"
        set group-name "TRUE"
      next
    end
  next
end

```

Once these settings are in place, users that are a member of the `ldap` user group will be able to authenticate.

To ensure your settings are correct, here is the sample output from a `diag debug` command that shows the authentication process.

When the "Allow Dial-in" attribute is set to "TRUE" the following will likely be in the output:

```

get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='TRUE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Passed group matching

```

If the attribute is not set but it is expected, the following will likely be in the output:

```

get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='FALSE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Failed group matching

```

The only difference between these two outputs is the last line which is either passed or failed based on if the member-attribute is set to the expected value or not.

## RADIUS SSO example

A common RADIUS SSO topology involves a medium sized company network of users connecting to the Internet through the FortiGate unit, and authenticating with a RADIUS server. RADIUS SSO authentication was selected because it is fast and relatively easy to configure.

This section includes:

- [Assumptions](#)
- [Topology](#)
- [Configuring RADIUS](#)
- [Configuring FortiGate regular and RADIUS SSO security policies](#)
- [Testing](#)

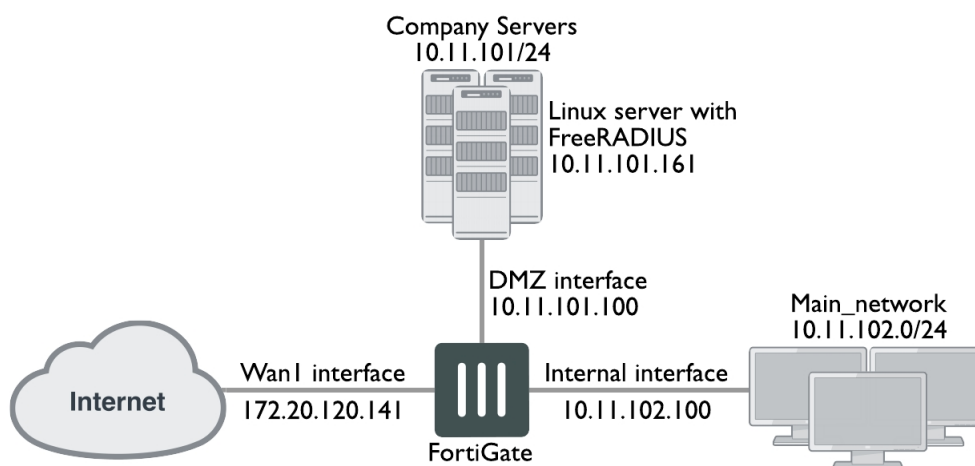

### Assumptions

- VDOMs are not enabled
- The admin super\_admin administrator account will be used for all FortiGate unit configuration.
- Any other devices on the network do not affect the topology of this example, and therefore are not included.
- Anywhere settings are not described, they are assumed to be default values.
- A RADIUS server is installed on a server or FortiAuthenticator unit and uses default attributes.
- BGP is used for any dynamic routing.
- Authentication event logging under Log&Report has been configured.

### Topology

Example.com has an office with 20 users on the internal network. These users need access to the Internet to do their jobs. The office network is protected by a FortiGate-60C unit with access to the Internet through the wan1 interface, the user network on the internal interface, and all the servers are on the DMZ interface. This includes an Ubuntu Linux server running FreeRADIUS. For this example only two users will be configured — Pat Lee with an account name `plee`, or `plee@example.com`, and Kelly Green with an account name `kgreen`, or `kgreen@example.com`.

### RADIUS SSO topology

## Configuring RADIUS

Configuring RADIUS includes configuring the RADIUS server such as FreeRADIUS, a radius client on user's computers, and configuring users in the system. For this example the two users will be Pat Lee, and Kelly Green. They belong to a group called `example.com_employees`. When it is all configured, the RADIUS daemon needs to be started.

The users have a RADIUS client installed on their PCs that allows them to authenticate through the RADIUS server.

FreeRADIUS can be found on the [freeradius.org](http://freeradius.org) website. For any problems installing FreeRADIUS, see the FreeRADIUS documentation.

## Configuring FortiGate interfaces

Before configuring the RADIUS SSO security policy, configure FortiGate interfaces. This includes defining a DHCP server for the internal network as this type of network typically uses DHCP. The wan1 and dmz interfaces are assigned static IP addresses and do not need a DHCP server.

### FortiGate interfaces used in this example

Interface	Subnet	Act as DHCP Server	Devices
wan1	172.20.120.141	No	Internet Service Provider
dmz	10.11.101.100	No	Servers, including RADIUS server
internal	10.11.102.100	Yes: x.x.x.110-.250	Internal user network

### To configure FortiGate interfaces - web-based manager:

1. Go to **Network > Interfaces**.
2. Select wan1 to edit.
3. Enter the following information and select **OK**.

<b>Alias</b>	Internet
<b>Addressing Mode</b>	Manual
<b>IP/Network Mask</b>	172.20.120.141/255.255.255.0
<b>Administrative Access</b>	HTTPS, SSH
<b>Enable DHCP Server</b>	Not selected
<b>Comments</b>	Internet
<b>Administrative Status</b>	Up

4. Select dmz to edit.
5. Enter the following information and select **OK**.

<b>Alias</b>	Servers
<b>Addressing Mode</b>	Manual
<b>IP/Network Mask</b>	10.11.101.100/255.255.255.0
<b>Administrative Access</b>	HTTPS, SSH, PING, SNMP
<b>Enable DHCP Server</b>	Not selected
<b>Listen for RADIUS Accounting Messages</b>	Select
<b>Comments</b>	Servers
<b>Administrative Status</b>	Up

6. Select internal to edit.
7. Enter the following information and select **OK**.

<b>Alias</b>	Internal network
<b>Addressing Mode</b>	Manual
<b>IP/Network Mask</b>	10.11.102.100/255.255.255.0
<b>Administrative Access</b>	HTTPS, SSH, PING
<b>Enable DHCP Server</b>	Select
<b>Address Range</b>	10.11.102.110 - 10.11.102.250
<b>Netmask</b>	255.255.255.0
<b>Default Gateway</b>	Same as Interface IP
<b>DNS Server</b>	Same as System DNS
<b>Comments</b>	Internal network
<b>Administrative Status</b>	Up

### Configuring a RADIUS SSO Agent on the FortiGate unit

To create a RADIUS SSO agent:

1. Go to **User & Device > Single Sign-On** and select **Create New**.
2. In **Type**, select **RADIUS Single-Sign-On Agent**.
3. Select **Use RADIUS Shared Secret** and enter the RADIUS server shared secret.
4. Select **Send RADIUS Responses**.
5. Select **OK**.  
The Single Sign-On agent is named RSSO\_Agent.

## Creating a RADIUS SSO user group

To define a local user group for RADIUS SSO:

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a Name for the user group.
3. In **Type**, select **RADIUS Single Sign-On (RSSO)**.
4. In **RADIUS Attribute Value**, enter the name of the RADIUS user group this local user group represents.
5. Select **OK**.

## Configuring FortiGate regular and RADIUS SSO security policies

With the RADIUS server and FortiGate interfaces configured, security policies can be configured. This includes both RADIUS SSO and regular policies, as well as addresses and address groups. All policies require NAT to be enabled.

### Security policies required for RADIUS SSO

Seq. No.	From -> To	Type	Schedule	Description
1	internal -> wan1	RADIUS SSO	business hours	Authenticate outgoing user traffic.
2	internal -> wan1	regular	always	Allow essential network services and VoIP.
3	dmz -> wan1	regular	always	Allow servers to access Internet.
4	internal -> dmz	regular	always	Allow users to access servers.
5	any -> any	deny	always	Implicit policy denying all traffic that hasn't been matched.

The RADIUS SSO policy must be placed at the top of the policy list so it is matched first. The only exception to this is if you have a policy to deny access to a list of banned users. In this case, that policy must go at the top so the RADIUS SSO does not mistakenly match a banned user or IP address.

This section includes:

- [Schedules, address groups, and services groups](#)
- [Configuring regular security policies](#)
- [Configuring RADIUS SSO security policy](#)

### Schedules, address groups, and services groups

This section lists the lists that need to be configured before security policies are created. Creating these lists is straight forward, so the essential information has been provided here but not step by step instructions. For more

information on firewall related details, see

### Schedules

Only one schedule needs to be configured — `business_hours`. This is a fairly standard Monday to Friday 8am to 5pm schedule, or whatever days and hours covers standard work hours at the company.

### Address groups

The following address groups need to be configured before the security policies.

Address Group Name	Interface	Address range included
internal_network	internal	10.11.102.110 to 10.11.102.250
company_servers	dmz	10.11.101.110 to 10.11.101.250

### Service groups

The following service groups need to be configured before the security policies. Note that the services listed are suggestions and may include more or less as required.

Service Group Name	Interface	Description of services to be included
essential_network_services	internal	Any network protocols required for normal network operation such as DNS, NTP, BGP.
essential_server_services	dmz	All the protocols required by the company servers such as BGP, HTTP, HTTPS, FTP, IMAP, POP3, SMTP, IKE, SQL, MYSQL, NTP, TRACEROUTE, SOCKs, and SNMP.
user_services	internal	Any protocols required by users HTTP, HTTP, FTP,

The following security policy configurations are basic and only include logging, and default AV and IPS.

### Configuring regular security policies

Regular security policies allow or deny access for non-RADIUS SSO traffic. This is essential as there are network services—such as DNS, NTP, and FortiGuard—that require access to the Internet.

#### To configure regular security policies - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy**, and select **Create New**.
2. Enter the following information, and select **OK**.

<b>Incoming Interface</b>	Internal
---------------------------	----------

<b>Source Address</b>	internal_network
<b>Outgoing Interface</b>	wan1
<b>Destination Address</b>	all
<b>Schedule</b>	always
<b>Service</b>	essential_network_services
<b>Action</b>	ACCEPT
<b>NAT</b>	ON
<b>Security Profiles</b>	ON: AntiVirus, IPS
<b>Log Allowed Traffic</b>	ON
<b>Comments</b>	Essential network services

3. Select **Create New**, enter the following information, and select **OK**.

<b>Incoming Interface</b>	dmz
<b>Source Address</b>	company_servers
<b>Outgoing Interface</b>	wan1
<b>Destination Address</b>	all
<b>Schedule</b>	always
<b>Service</b>	essential_server_services
<b>Action</b>	ACCEPT
<b>NAT</b>	ON
<b>Security Profiles</b>	ON: AntiVirus, IPS
<b>Log Allowed Traffic</b>	enable
<b>Comments</b>	Company servers accessing the Internet

4. Select **Create New**, enter the following information, and select **OK**.

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	internal_network
<b>Outgoing Interface</b>	dmz
<b>Destination Address</b>	company_servers

<b>Schedule</b>	always
<b>Service</b>	all
<b>Action</b>	ACCEPT
<b>NAT</b>	ON
<b>Security Profiles</b>	ON: AntiVirus, IPS
<b>Log Allowed Traffic</b>	enable
<b>Comments</b>	Access company servers

### Configuring RADIUS SSO security policy

The RADIUS SSO policy allows access for members of specific RADIUS groups.

To configure RADIUS SSO security policy:

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Enter the following information:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	internal_network
<b>Source User(s)</b>	Select the user groups you created for RSSO.
<b>Outgoing Interface</b>	wan1
<b>Destination Address</b>	all
<b>Schedule</b>	business_hours
<b>Service</b>	ALL
<b>Action</b>	ACCEPT
<b>NAT</b>	ON
<b>Security Profiles</b>	ON: AntiVirus, WebFilter, IPS, and Email Filter. In each case, select the default profile.

4. Select **OK**.
5. To ensure an RSSO-related policy is matched first, the policy should be placed higher in the security policy list than more general policies for the same interfaces.
6. Select **OK**.

## Testing

Once configured, a user only needs to log on to their PC using their RADIUS account. After that when they attempt to access an Internet website, the FortiGate unit will use their session information to get their RADIUS information. Once the user is verified, they are allowed access to the website.

To test the configuration perform the following steps:

1. Have user 'plee' logon to their PC, and try to access an Internet website.
2. The FortiGate unit will contact the RADIUS server for user plee's information. Once confirmed, plee will have access to the website. Each step generates log entries that enable you to verify that each step was successful.
3. If a step is unsuccessful, confirm that your configuration is correct.

### RADIUS SSO test

## Troubleshooting

In the web-based manager, a good tool for troubleshooting is the packet counter column on the security policy page at **Policy & Objects > IPv4 Policy**. This column displays the number of packets that have passed through this security policy. Its value when you are troubleshooting is that when you are testing your configuration (end to end connectivity, user authentication, policy use) watching the packet count for an increase confirms any other methods you may be using for troubleshooting. It provides the key of which policy is allowing the traffic, useful information if you expect a user to require authentication and it never happens.

This section addresses how to get more information from the CLI about users and user authentication attempts to help troubleshoot failed authentication attempts.

```
diag firewall iprope list
```

Shows the IP that the computer connected from. This is useful to confirm authorization and VPN settings.

```
diag firewall iprope clear
```

Clear all authorized users from the current list. Useful to force users to re-authenticate after system or group changes. However, this command may easily result in many users having to re-authenticate, so use carefully.

```
diag rso query ip  
diag rso query rso-key
```

Queries the RSSO database.

For more information on troubleshooting specific features, go to that section of this document. Most sections have troubleshooting information at the end of the section. In addition to that information, see the [FortiOS Handbook Troubleshooting](#) guide for general troubleshooting information.

# Chapter 4 - Best Practices

## Introduction

This FortiGate Best Practices document is a collection of guidelines to ensure the most secure and reliable operation of FortiGate units in a customer environment. It is updated periodically as new issues are identified.

## General Considerations

1. For security purposes, NAT mode is preferred because all of the internal or DMZ networks can have secure private addresses. NAT mode policies use network address translation to hide the addresses in a more secure zone from users in a less secure zone.
2. Use virtual domains (VDOMs) to group related interfaces or VLAN subinterfaces. Using VDOMs will partition networks and create added security by limiting the scope of threats.
3. Use Transparent mode when a network is complex and does not allow for changes in the IP addressing scheme.

## Customer service and technical support

For antivirus and attack definition updates, firmware updates, updated product documentation, technical support information, and other resources, please visit the Fortinet Technical Support web site at <http://support.fortinet.com>.

You can also register Fortinet products and service contracts from <http://support.fortinet.com> and change your registration information at any time.

For information about our priority support hotline (live support), see <http://support.fortinet.com>.

When requesting technical support, please provide the following information:

- Your name, and your company's name and location
- Your email address and/or telephone number
- Your support contract number (if applicable)
- The product name and model number
- The product serial number (if applicable)
- The software or firmware version number
- A detailed description of the problem

## Fortinet Knowledge Base

The most recent Fortinet technical documentation is available from the Fortinet Knowledge Base. The knowledge base contains short how-to articles, FAQs, technical notes, product and feature guides, and much more. Visit the Fortinet Knowledge Base at <http://kb.fortinet.com>.

### **Comments on Fortinet technical documentation**

Please send information about any errors or omissions in this document, or any Fortinet technical documentation, to [techdoc@fortinet.com](mailto:techdoc@fortinet.com).

## System and performance

By implementing the following best practices for system and performance, you will ensure maximum efficiency of your FortiGate device. Be sure to read everything carefully, particularly the section that concerns shutting down the FortiGate system, in order to avoid potential hardware issues.

### Performance

- Disable any management features you do not need. If you don't need SSH or SNMP, disable them. SSH also provides another possibility for would-be hackers to infiltrate your FortiGate unit.
- Put the most used firewall rules to the top of the interface list.
- Log only necessary traffic. The writing of logs, especially if to an internal hard disk, slows down performance.
- Enable only the required application inspections.
- Keep alert systems to a minimum. If you send logs to a syslog server, you may not need SNMP or email alerts, making for redundant processing.
- Establish scheduled FortiGuard updates at a reasonable rate. Daily updates occurring every 4-5 hours are sufficient for most situations. In more heavy-traffic situations, schedule updates for the evening when more bandwidth can be available.
- Keep security profiles to a minimum. If you do not need a profile on a firewall rule, do not include it.
- Keep VDOMs to a minimum. On low-end FortiGate units, avoid using them if possible.
- Avoid traffic shaping if you need maximum performance. Traffic shaping, by definition, slows down traffic.

### Shutting down

Always shut down the FortiGate operating system properly before turning off the power switch to avoid potentially catastrophic hardware problems.

#### To power off the FortiGate unit - web-based manager:

1. Go to **Dashboard**.
2. In the **System Resources** widget, select **Shutdown**.

#### To power off the FortiGate unit – CLI:

```
execute shutdown
```

Once this has been done, you can safely turn off the power switch or disconnect the power cables from the power supply.

## Migration

Network administrators are often reluctant to change firewall vendors due to the perception that the migration process is difficult. Indeed, there is no point hiding the fact that moving to a new vendor requires careful consideration. But concern over the potential pain of migration should not stand in the way of adopting new security technologies. The purpose of this chapter is to describe the best practices for performing such migrations and ultimately to ease the migration process itself.

### Information gathering

It is always best practice to perform a full network audit prior to any migration. This should include:

- Full back up of all security systems (including switches, routers) in case a back-out needs to be performed.
- Physical and logical network diagram with visual audit

Understanding exactly where cables run in the network and verifying they are all correctly labeled is essential to avoid mistakes and unnecessary downtime during the upgrade. Don't overlook simple things such as:

- Do I have enough spare interfaces on my switches?
- Do I have the right fiber (single/multi mode) and right connectors (LC, FC, MTRJ, SC, ST)?
- Do I have spare cables? (in the heat of the moment, it is a simple mistake to break an RJ-45 connector or damage a fiber)
- Do I have space in the rack for the new equipment?
- Do I have enough power sockets?

No matter how securely a FortiGate is configured in the network, it cannot help if it has been bypassed; visually checking where the device sits in the network in relation to other devices will ensure you are maintaining security and verify the network diagram is 'as built'. Details of all networks including subnet masks should be documented at this point to ensure that the replacement device is configured with the correct information.

### Object and policy migration

Whilst we have suggested some level of manual review is included in the policy migration, it can be useful to be able to automatically migrate simply between another vendor's format and the FortiGate format. The FortiGate policy format is text based and can easily be cut and pasted into from other vendor formats however, responding to the high customer demand to migrate away from other vendors, Fortinet have released an automatic configuration migration tool at <http://convert.fortinet.com> to simplify this process. Supporting Cisco ACLs, PIX, ASA, Check Point, and Juniper, the Converter can securely upload and convert the policy into the Fortinet format.

### Testing and validation

This is an important process and should be tested offline first wherever possible i.e. configure the policy in the lab or on a test network and verify that the required access permissions are being implemented. To really test the solution out, the FortiGate can be implemented on the live network with a different gateway IP and the selected user pointed to the new gateway. This allows a staged approach to migrating the new platform into the network ensuring that the process does not interrupt day to day operations.

## Going live and obtaining feedback

If testing and validation is successful at this point, you can migrate to the new firewall either by switching IP's and removing the old devices or by changing the default gateway in DHCP. Once the firewall is in place, acceptance testing will of course need to be carried out and an iterative process of tuning undertaken to finalize the configuration.

## Adding new services

The Fortinet solution will have a plethora of additional features compared to your previous vendor and it is very tempting to start switching them on but it is a good idea to wait and validate the new firewall as was previously configured before adding new functions as this simplifies testing and problem diagnosis. Finally complete the migration (don't forget about the Plan Do Check Act Cycle) by adding any new services that were requested and learn about the multiple features you have available with the FortiGate appliance.

## Environmental specifications

Keep the following environmental specifications in mind when installing and setting up your FortiGate unit.

- Operating temperature: 32 to 104°F (0 to 40°C). Temperatures may vary, depending on the FortiGate model.
- If you install the FortiGate unit in a closed or multi-unit rack assembly, the operating ambient temperature of the rack environment may be greater than room ambient temperature.  
Therefore, make sure to install the equipment in an environment compatible with the manufacturer's maximum rated ambient temperature.
- Storage temperature: -13 to 158°F (-25 to 70°C). Temperatures may vary, depending on the FortiGate model.
- Humidity: 5 to 90% non-condensing.
- Air flow - For rack installation, make sure that the amount of air flow required for safe operation of the equipment is not compromised.
- For free-standing installation, make sure that the appliance has at least 1.5 in. (3.75 cm) of clearance on each side to allow for adequate air flow and cooling.

Depending on your device, the FortiGate may generate, use, and even radiate radio frequency energy and, if not installed and used in accordance with the instructions, may cause harmful interference to radio communications. However, there is no guarantee that interference will not occur in a particular installation. If the equipment does cause harmful interference to radio or television reception, which can be determined by turning the equipment off and on, the user is encouraged to try to correct the interference by one or more of the following measures:

- Reorient or relocate the receiving antenna.
- Increase the separation between the equipment and receiver.
- Connect the equipment into an outlet on a circuit different from that to which the receiver is connected.
- Consult the dealer or an experienced radio/TV technician for help.

Explosion is a serious risk if the battery is replaced by an incorrect type. Dispose of used batteries according to the instructions. To reduce the risk of fire, use only No. 26 AWG or larger UL Listed or CSA Certified Telecommunication Line Cord.

## Grounding

- Ensure the FortiGate unit is connected and properly grounded to a lightning and surge protector. WAN or LAN connections that enter the premises from outside the building should be connected to an Ethernet CAT5 (10/100 Mb/s) surge protector.
- Shielded Twisted Pair (STP) Ethernet cables should be used whenever possible rather than Unshielded Twisted Pair (UTP).
- Do not connect or disconnect cables during lightning activity to avoid damage to the FortiGate unit or personal injury.

## Rack mounting

- **Elevated Operating Ambient** - If installed in a closed or multi-unit rack assembly, the operating ambient temperature of the rack environment may be greater than room ambient.  
Therefore, consideration should be given to installing the equipment in an environment compatible with the maximum ambient temperature (Tmax) specified by the manufacturer.

- **Reduced Air Flow** - Installation of the equipment in a rack should be such that the amount of air flow required for safe operation of the equipment is not compromised.
- **Mechanical Loading** - Mounting of the equipment in the rack should be such that a hazardous condition is not achieved due to uneven mechanical loading.
- **Circuit Overloading** - Consideration should be given to the connection of the equipment to the supply circuit and the effect that overloading of the circuits might have on overcurrent protection and supply wiring. Appropriate consideration of equipment nameplate ratings should be used when addressing this concern.
- **Reliable Earthing** - Reliable earthing of rack-mounted equipment should be maintained.

Particular attention should be given to supply connections other than direct connections to the branch circuit (e.g. use of power strips).

## Firmware

Firmware upgrading and downgrading sounds pretty simple, anyone can do it, right? The mark of a professional is not that they can do something correctly, or even do it correctly over and over again. A professional works in such a way that, if anything goes wrong they are prepared and able to quickly get things back to normal. Firmware updates can go wrong just like anything else. So a real professional does things in a way that minimizes their risk and follows some best practices, as listed below.

### Firmware change management

Consider the following five points when performing firmware upgrades, not only in FortiOS but in general. This applies to pretty much any change you have to do in a production environment.

#### Understanding the new version first

Before attempting any changes in production, first make sure you set up a laboratory where you can freely play with the new features, and understand them with enough time and no pressure. Read the Release Notes, Manuals, and other documentation like presentations, videos, or podcasts about the new version.

You are ready to explain the need for an upgrade once you understand:

- The differences and the enhancements between the new version and the previous version(s).
- The impact of the upgrade on customers and the users of the operating platform.
- The known limitations that might affect your environment.
- The potential risks when performing the upgrade.
- The licensing changes that may apply.

Never attempt to upgrade to a version you don't fully understand (both on features and known limitations), and on which you have no operational experience.

---

#### Have a valid reason to upgrade

The reason can NOT be "Because I want to have the latest version". The reason has to be explained in terms of business, technical, and/or operational improvement.

Affirmative answers to the following questions are valid reasons to upgrade:

- Does the new version have a feature that helps to ensure compliance?
- Does the new version have an enhancement that allows 40% decrease (40% improvement) on the time to perform a certain operation?
- Does the new feature correct a known defect/bug found on a previous version that affects the company business/operations?
- Will the new version allow your organization to deploy new services that will help to gain new customers or increase loyalty of existing ones?
- Is the vendor cutting support for the version your organization is currently using?

If the best reason to upgrade is “Because the new features seem to be cool” or “Because I want to have the latest version”, a little more understanding and planning may be necessary.

### Prepare an upgrade plan

If you choose to upgrade because you found a valid reason to do so, make sure you create a plan that covers business, technical, and operational aspects of the upgrade:

#### Business:

Proper planning and justification for an upgrade should be proportional to how critical the system is to the business.

- Make sure you can clearly articulate the benefits of the upgrade in business terms (time, money, and efficiency).
- Understand the business processes that will be affected by the change.
- Make sure the upgrade maintenance window is not close to a business-critical process (such as quarterly or monthly business closure).
- Obtain executive and operational approval for the maintenance window. The approval must come from the owners of ALL the systems/information affected by the upgrade, not only from those that own the system being upgraded. The approval must be done in a formal (written or e-mail) form.

#### Technical and operational:

- Re-read the Release Notes for the technology you are upgrading. Supported hardware models, upgrade paths, and known limitations should be clearly understood.
- Make sure your upgrade maintenance window does not overlap with any other maintenance window on your infrastructure.
- If you have any premium support offer (such as TAM, Premium Support), do a capacity planning exercise to ensure the new firmware/software version does not take more hardware resources than you currently have.
- Create a backup, whether or not you have scheduled backups. Create a new fresh backup.
- Obtain offline copies of both the currently installed firmware and the new version.
- Create a list of systems with inter-dependencies to the system you are upgrading. For example, if you are upgrading a FortiGate; understand the impact on any FortiAP, FortiAuthenticator, FortiToken, FortiManager, or FortiAnalyzer you have on your environment.
- Ensure you have a list of adjacent devices to the upgrading platform and have administrative access to them, just in case you need to do some troubleshooting. Are you upgrading FortiWeb? Make sure you can administratively access the Web Applications. Are you upgrading a FortiGate? Make sure you can administratively access the surrounding switches and routers.
- Have a step-by-step plan on how to perform and test the upgrade. You want to make sure you think of the worst situation before it happens, and have predefined courses of action, instead of thinking under pressure when something already went wrong.
- Define a set of tests (that include critical business applications that should be working) to make sure the upgrade went fine. If any test does not go well, define which ones mandate a rollback and which ones can be tolerated for further troubleshooting. This set of tests should be run before and after the upgrade to compare results, and they should be the same.
- Define a clear rollback plan. If something goes wrong with the upgrade or the tests, the rollback plan will help you get your environment back to a known and operational status. The plan must clearly state the conditions under which the rollback will be started.

- Declare configuration freezes. A little bit before and after the upgrade. The idea is to reduce the amount of variables to take into consideration if something goes wrong.
- Perform a “Quality Assurance” upgrade. Grab a copy of the production configuration, load it on a non-production box and execute the upgrade there to see if there are any issues on the process. Then adjust your plan according to the results you obtained.
- Have a list of information elements to be gathered if something goes wrong. This ensures that, even if the upgrade fails, you will collect enough information so you can troubleshoot the issue without needing to repeat the problem. Get help from TAC/Support departments if you need to check what else could be missing on your list.
- Define a test monitoring period after the change was completed. Even if the upgrade went smoothly, something could still go wrong. Make sure you monitor the upgraded system for at least one business cycle. Business cycles may be a week, a month, or a quarter, depending on your organization’s business priorities.

## Execute the upgrade plan

Execution of an upgrade is just as key as planning.

Once you are performing the upgrade, the pressure will rise and stress might peak. This is why you should stick to the plan you created with a cool head.

Resist the temptation to take decisions while performing the upgrade, as your judgment will be clouded by the stress of the moment, even if a new decision seems to be “obvious” at such time. If your plan says you should rollback, then execute the rollback despite the potential “We-can-fix-this-very-quickly” mentality.

While performing the upgrade, make sure all the involved components are permanently monitored before, during, and after the upgrade, either via monitoring systems, SNMP alerts, or at least with tools like a ping. Critical resources like CPU, memory, network, and/or disk utilization must also be constantly monitored.

To avoid misunderstandings, when performing the tests for each critical application defined on the planning, make sure there are formal notifications on the results for each user area, service, system, and/or application tested.

Regardless if you have to rollback or not, if a problem occurs, make sure you gather as much information about the problem as possible, so you can later place a support ticket to find a solution.

Last but not least, document the upgrade:

- Enable your terminal emulation program to leave trace of all the commands executed and all the output generated. If you are performing steps via GUI, consider using a video capture tool to document it.
- Document any command or change performed over the adjacent/interdependent systems. Make sure they are acknowledged by the relevant administrators
- Document any deviations performed over the upgrade plan. This is planned-versus-actual.

## Learn more about change management

Change Management and Change Control are huge knowledge areas in the field of Information Systems and Computer/Network Security.

This document is by no means a comprehensive list on what you should do when performing an upgrade, with either Fortinet or any other technology. It is merely a list of important things you should take into consideration when performing upgrades which are the result of years of experience dealing with changes on critical environments, as it is common that security devices are protecting critical applications and processes.

There are vast resources on the topic: books, public white papers, blog entries, etc. If you search the Internet for the “Change Control Best Practices” or “Change Management Best Practices” you will get many interesting documents.

Changes on production IT infrastructure are critical to the business. Make sure they play in your favor and not against you.

---

## Performing a firmware upgrade

Upgrading a firewall is something that should be compared to upgrading the operating system on your computer. It's not to be taken lightly! You want to make sure everything is backed up and you have some options available if things go awry. Assuming it all seems to work you also want a list of things to do in order to confirm everything is working properly. Finally, you need enough time to do it. All really simple stuff, but what does this mean in relation to upgrading your FortiGate? It means, you follow these simple steps:

- 1. Backup and store old configuration (full configuration backup from CLI).**

Digging into this a little, step 1 is easy to understand. Do a full backup of your old configuration. This is all part of your disaster recovery plan. If the upgrade fails in some way you need to make sure you can get the Firewall back up and running. The best way to do this is to get it back to a state where you know what the behavior was. For more information, refer to ["Performing a configuration backup" on page 587](#).

- 2. Have copy of old firmware available.**

Step 2, is also part of your disaster recovery. If the upgrade fails you might be able to switch the active partition. But as a Professional, you need to be prepared for the worst case scenario where you can't do that. Which means you'll need your old firmware.

- 3. Have disaster recovery option on standby – especially if remote.**

Step 3, is your plan for what to do in the event of a critical failure. As we're talking FortiGate this means that your firewall doesn't come back after the upgrade. What this means is that you need to be able to get to the console port in order to find out why. Maybe it's DHCP and the IP changed, maybe the OS is corrupt, who knows? Get to the console and find out.

There could be a simple fix. If there's not, then be prepared for a format and TFTP reload.

- 4. Read the release notes, including the upgrade path and bug information.**

Step 4, READ THE RELEASE NOTES. They contain all kinds of information, known bugs, fixed bugs even upgrade issues like lost configuration settings. Not all upgrade information is ever contained in any products release notes. That does not mean they are devoid of good/useful information. Read them, digest them, then a few days later read them again.

- 5. Double check everything.**

Step 5, do a double check of everything. Is your TFTP server working, does your console connection function, is there anything in the release notes that could impact your upgrade procedure, do you have your configuration backed up? Make sure you've done everything.

- 6. Upgrade.**

Step 6, do the upgrade. Doing an upgrade doesn't take very long, a few minutes (less a lot of times) but make sure you schedule enough time for it. At the end of the day an upgrade can succeed or fail. If it succeeds you want some time to check/confirm that any important features you have are working (VPNs etc). If it fails you'll need time to sort things out.

## Performing a firmware downgrade

Just like upgrading, you need to make sure it's done properly. While similar, the steps are somewhat different since there are other pitfalls in this case.

- 1. Locate pre-upgrade configuration file.**

Step 1 is very important. This is why, when you upgrade you make a backup of your old configuration and save it. If you don't, then you'll need to rebuild manually.

- 2. Have copy of old firmware available.**

Step 2 is fairly obvious. Even with devices that have multiple partitions and your downgrade process is simply going to be to switch the active partition, this could go wrong. In which case, you may be without Internet access. A professional has a plan for when things go wrong.

- 3. Have disaster recovery option on standby – especially if remote.**

Step 3 is no different from before. Hopefully you don't need to format the unit, but be prepared for that, just in case.

- 4. Read the release notes – is a downgrade possible, or necessary?**

Step 4, once again, is to READ THE RELEASE NOTES. In this case, you will need to do this for the version you are on, and the version you are downgrading too, and everything in between (if you are going back multiple major releases or patches). Maybe the OS switched from 32 to 64 bits somewhere between the two firmware releases. In order to make sure you don't get nailed by something like that you need to check the upgrade and downgrade information in every major release and patch, as it may have a direct impact on your options.

- 5. Double check everything.**

- 6. Downgrade – all settings, except those needed for access, are lost.**

Step 5 and 6 are the same as before. Double check everything, then downgrade.

- 7. Restore pre-upgrade configuration.**

Step 7 is new. Obviously most settings are lost when you downgrade so in order to get back up and running you will need to restore your old configuration file.

## Performing a configuration backup

Once you configure the FortiGate unit and it is working correctly, it is extremely important that you backup the configuration. In some cases, you may need to reset the FortiGate unit to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device will have to be recreated, unless a backup can be used to restore it.

It is also recommended that once any further changes are made that you backup the configuration immediately, to ensure you have the most current configuration available. Also, ensure you backup the configuration before upgrading the FortiGate unit's firmware. Should anything happen during the upgrade that changes the configuration, you can easily restore the saved configuration.

Always backup the configuration and store it on the management computer or off-site. You have the option to save the configuration file to various locations including the local PC, USB key, FTP and TFTP site. The latter two are configurable through the CLI only.

If you have VDOMs, you can back up the configuration of the entire FortiGate unit or only a specific VDOM. Note that if you are using FortiManager or FortiCloud, full backups are performed and the option to backup individual VDOMs will not appear.

**To back up the FortiGate configuration - web-based manager:**

1. Go to **Dashboard**.
2. On the **System Information** widget, select **Backup** next to **System Configuration**.
3. Select to backup to your **Local PC** or to a **USB Disk**.  
The **USB Disk** option will be grayed out if no USB drive is inserted in the USB port. You can also backup to the FortiManager using the CLI.
4. If VDOMs are enabled, select to backup the entire FortiGate configuration (**Full Config**) or only a specific VDOM configuration (**VDOM Config**).
5. If backing up a VDOM configuration, select the VDOM name from the list.
6. Select **Encrypt configuration file**.  
Encryption must be enabled on the backup file to back up VPN certificates.
7. Enter a password and enter it again to confirm it. You will need this password to restore the file.
8. Select **Backup**.
9. The web browser will prompt you for a location to save the configuration file. The configuration file will have a .conf extension.

**To back up the FortiGate configuration - CLI:**

```
execute backup config management-station <comment>
```

... or ...

```
execute backup config usb <backup_filename> [<backup_password>]
```

... or for FTP (note that port number, username are optional depending on the FTP site)...

```
execute backup config ftp <backup_filename> <ftp_server> [<port>] [<user_name>]
[<password>]
```

... or for TFTP ...

```
execute backup config tftp <backup_filename> <tftp_servers> <password>
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config vdom
edit <vdom_name>
```

**Backing up a configuration file using SCP**

You can use secure copy protocol (SCP) to download the configuration file from the FortiGate unit as an alternative method of backing up the configuration file or an individual VDOM configuration file. This is done by enabling SCP for an administrator account and enabling SSH on a port used by the SCP client application to connect to the FortiGate unit. SCP is enabled using the CLI commands:

```
config system global
set admin-scp enable
end
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config global
set admin-scp enable
end
```

```
config vdom
  edit <vdom_name>
```

## Security Profiles (AV, Web Filtering etc.)

Infection can come from many sources and have many different effects. Because of this, there is no single means to effectively protect your network. Instead, you can best protect your network with the various UTM tools your FortiGate unit offers.

### Firewall

- Be careful when disabling or deleting firewall settings. Changes that you make to the firewall configuration using the GUI or CLI are saved and activated immediately.
- Arrange firewall policies in the policy list from more specific to more general. The firewall searches for a matching policy starting from the top of the policy list and working down. For example, a very general policy matches all connection attempts. When you create exceptions to a general policy, you must add them to the policy list above the general policy.
- Avoid using the All selection for the source and destination addresses. Use addresses or address groups.
- If you remove all policies from the firewall, there are no policy matches and all connections are dropped.
- If possible, avoid port ranges on services for security reasons.
- The settings for a firewall policy should be as specific as possible. Do not use 0.0.0.0 as an address. Do not use Any as a service. Use subnets or specific IP addresses for source and destination addresses and use individual services or service groups.
- Use a 32-bit subnet mask when creating a single host address (for example, 255.255.255.255).
- Use logging on a policy only when necessary and be aware of the performance impact. For example, you may want to log all dropped connections but can choose to use this sparingly by sampling traffic data rather than have it continually storing log information you may not use.
- It is possible to use security policies based on 'any' interface. However, for better granularity and stricter security, explicit interfaces are recommended.
- Use the comment field to input management data, for example: who requested the rule, who authorized it, etc.
- Avoid FQDN addresses if possible, unless they are internal. It can cause a performance impact on DNS queries and security impact from DNS spoofing.
- For non vlan interfaces, use zones (even if you have only one single interface for members) to allow:
  - An explicit name of the interface to use in security policies ('internal' is more explicit than 'port10').
  - A split between the physical port and its function to allow port remapping (for instance moving from a 1G interface to a 10G interface) or to facilitate configuration translation, as performed during hardware upgrades.

### Security

- Use NTP to synchronize time on the FortiGate and the core network systems, such as email servers, web servers, and logging services.
- Enable log rules to match corporate policy. For example, log administration authentication events and access to systems from untrusted interfaces.
- Minimize adhoc changes to live systems, if possible, to minimize interruptions to the network. When not possible, create backup configurations and implement sound audit systems using FortiAnalyzer and FortiManager.
- If you only need to allow access to a system on a specific port, limit the access by creating the strictest rule possible.

## Authentication

- You must add a valid user group to activate the Authentication check box on the firewall policy configuration page.
- Users can authenticate with the firewall using HTTP or FTP. For users to be able to authenticate, you must add an HTTP or FTP policy that is configured for authentication.

## Antivirus

- Enable antivirus scanning at the network edge for all services.
- Use FortiClient endpoint antivirus scanning for protection against threats that get into your network.
- Subscribe to FortiGuard AntiVirus Updates and configure your FortiGate unit to receive push updates. This will ensure you receive antivirus signature updates as soon as they are available.
- To ensure that all AV push updates occur, ensure you have an AV profile enabled in a security policy.
- Enable only the protocols you need to scan. If you have antivirus scans occurring on the SMTP server, or use FortiMail, it is redundant to have scanning occur on the FortiGate unit as well.
- Reduce the maximum file size to be scanned. Viruses usually travel in small files of around 1 to 2 megabytes.
- Do not quarantine files unless you regularly monitor and review them. This is otherwise a waste of space and impacts performance.
- Examine antivirus reports and log messages periodically. Take particular notice of repeated detections. For example, repeated virus detection in SMTP traffic could indicate a system on your network is infected and is attempting to contact other systems to spread the infection using a mass mailer.

## Antispam

- If possible use, a FortiMail unit. The antispam engines are more robust.
- Use fast DNS servers.
- Use specific security profiles for the rule that will use antispam.
- DNS checks may cause false positive with HELO DNS lookup.
- Content analysis (banned words) may impose performance overhead.

## Intrusion Prevention System (IPS)

Your FortiGate's IPS system can detect traffic attempting to exploit this vulnerability. IPS may also detect when infected systems communicate with servers to receive instructions. Refer to the following list of best practices regarding IPS.

- Enable IPS scanning at the network edge for all services.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to FortiGuard IPS Updates and configure your FortiGate unit to receive push updates. This will ensure you receive IPS signature updates as soon as they are available.
- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to Block.
- Create and use security profiles with specific signatures and anomalies you need per-interface and per-rule.
- Do not use predefined or generic profiles. While these profiles are convenient to supply immediate protection, you should create profiles to suit your network environment.

- If you do use the default profiles, reduce the IPS signatures/anomalies enabled in the profile to conserve processing time and memory.
- If you are going to enable anomalies, make sure you tune thresholds according to your environment.
- If you need protection, but not audit information, disable the logging option.
- Tune the IP-protocol parameter accordingly.

### Blocking Skype using CLI options for improved detection

If you want to identify or block Skype sessions, use the following CLI command with your FortiGate's public IP address to improve detection (FortiOS 4.3.12+ and 5.0.2+):

```
config ips global
    set skype-client-public-ipaddr 198.51.100.0,203.0.113.0
end
```

Note that the above syntax is configured using multiple public IP addresses, where a single public IP address may suffice depending on your network configuration.

### Email filter

Spam is a common means by which attacks are delivered. Users often open email attachments they should not, and infect their own machine.

- Enable email filtering at the network edge for all types of email traffic.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to the FortiGuard AntiSpam Service.

### amURL filtering

Best practices for URL filtering can be divided into four categories: flow-based versus proxy based filtering; local category/rating feature; URL filter 'Exempt' action; and Deep Scan.

#### Flow-based versus proxy-based

Try to avoid mixing flow-based and proxy-based features in the same profile if you are not using IPS or Application Control.

#### Local category/rating feature

Local categories and local rating features consume a large amount of CPU resources, so use these features as little as possible. It is better to use Local categories instead of using the 'override' feature, since the 'override' feature is more complicated and more difficult to troubleshoot.

#### URL filter 'Exempt' action

When using the URL filter 'Exempt' option, webfilter, antivirus and dlp scans are bypassed by default, so use this option only for trusted sites.

**Configuration notes:** You need to configure 'Exempt' actions in the URL filter if you want to bypass the FortiGuard Web Filter. You can configure which particular inspection(s) you want to bypass using the `set exempt` command in `config webfilter urlfilter`.

## Deep Scan

The 'Deep Scan' feature is much heavier on resources than 'HTTPS URL Scan Only'. Deep Scan is much more accurate, since many sites (such as various Google applications) cannot be scanned separately without deep scanning enabled.

**Note:** If you configure Deep Scan in the SSL profile and then configure 'Enable HTTPS URL Scan Only' in the web filter profile, then Deep Scan is not performed.

## Web filtering

FortiGuard Web Filtering can help stop infections from malware sites and help prevent communication if an infection occurs.

- Enable FortiGuard Web Filtering at the network edge.
- Install the FortiClient application and use FortiGuard Web Filtering on any systems that bypass your FortiGate unit.
- Block categories such as Pornography, Malware, Spyware, and Phishing. These categories are more likely to be dangerous

## Patch management

When vulnerabilities are discovered in software, the software vendors release updates that fix these problems. Keeping your software and operating system up-to-date is a vital step to prevent infection and defend against attacks.

- Follow the latest advisories and reports on the FortiGuard webpage.
- Apply updates to all software as the updates become available.
- FortiGuard Vulnerability Management can help identify security weaknesses in your network. This subscription service is available through FortiScan and FortiAnalyzer units.
- Apply firmware updates to your FortiGate unit as they are released.
- Subscribe to FortiGuard AntiVirus and IPS services, so that AntiVirus and IPS scanning engines are automatically updated when new version are released.

## Policy configuration

Configuring the FortiGate unit with an 'allow all' traffic policy is very undesirable. While this does greatly simplify the configuration, it is less secure. As a security measure, it is best practice for the policy rulebase to 'deny' by default, and not the other way around.

### Policy configuration changes

On a heavy-loaded system, plan configuration changes during low usage periods in order to minimize impact on CPU usage and established sessions. In this scenario, it is considered a best practice to de-accelerate the hardware-accelerated sessions.

You can configure de-accelerated behaviour on hardware-accelerated sessions using CLI commands to control how the processor manages policy configuration changes. The following CLI commands are to be used:

```
config system settings
    set firewall-session-dirty { check-all | check-new | check-policy-option }
end
```

where you want the following to be true:

<code>check-all</code>	CPU flushes all current sessions and re-evaluates them. This is the default option.
<code>check-new</code>	CPU keeps existing sessions and applies policy changes to new sessions only. This reduces CPU load and the possibility of packet loss.
<code>check-policy-option</code>	Use the option selected in the <code>firewall-session-dirty</code> field of the firewall policy ( <code>check-all</code> or <code>check-new</code> , as above, but per policy).

### Policy whitelisting

- Allow only the necessary inbound and outbound traffic.
- If possible, limit traffic to specific addresses or subnets. This allows the FortiGate unit to drop traffic to and from unexpected addresses.

### IPS and DoS policies

- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to Block.
- Your FortiGate unit includes IPS signatures written to protect specific software titles from DoS attacks. Enable the signatures for the software you have installed and set the signature action to Block.
- DoS attacks are launched against vulnerabilities. Maintain a FortiGuard IPS subscription to ensure your FortiGate unit automatically receives new and updated IPS signatures as they are released.
- Use and configure DoS policies to appropriate levels based on your network traffic and topology. This will help drop traffic if an abnormal amount is received. The key is to set a good threshold. The threshold defines the maximum number of sessions/packets per second of normal traffic. If the threshold is exceeded, the action is triggered. Threshold defaults are general recommendations, but your network may require very different values. One way to find the correct values for your environment is to set the action to Pass and enable logging. Observe the logs and adjust the threshold values until you can determine the value at which normal traffic begins to generate attack reports. Set the threshold above this value with the margin you want. Note that the smaller the margin, the more protected your system will be from DoS attacks, but your system will also be more likely to generate false alarms.

## Networking

When configuring your network, ensure that there is no 'back door' access to the protected network. For example, if there is a wireless access point, it must be appropriately protected with password and encryption.

Be sure to also maintain an up-to-date network diagram which includes IP addressing, cabling, and network elements.

### Routing configuration

- Always configure a default route.
- Add blackhole routes for subnets reachable using VPN tunnels. This ensures that if a VPN tunnel goes down, traffic is not mistakenly routed to the Internet unencrypted.

### Policy routing

Keep the number of policy routes to a minimum to optimize performance in route lookup and to simplify troubleshooting.

### Dynamic routing

- Select a Router ID that matches an IP assigned to an interface. This avoids the likelihood of having two devices with the same router ID.
- For routing over an IPsec tunnel, assign IP addresses to both ends of the tunnel.

### Advanced routing

Use the following best practices for advanced routing when dealing with Border Gateway Protocol (BGP) and Open Shortest Path First (OSPF).

#### Border Gateway Protocol (BGP)

If you are using BGP, it is recommended that you enable soft-reconfiguration. This has two benefits:

- It allows you to perform 'soft clear' of peers after a change is made to a BGP policy.
- It provides greater visibility into the specific prefixes learned from each neighbor.

Leave soft-reconfiguration disabled if your FortiGate does not have much unused memory. Soft-reconfiguration requires keeping separate copies of prefixes received and advertised, in addition to the local BGP database.

#### Open Shortest Path First (OSPF)

- Avoid use of passive interfaces wherever possible.
- Avoid use of virtual links to connect areas. All areas should be designed to connect directly to the backbone area.
- Ensure that all backbone routers have a minimum of two peering connections to other backbone neighbors.
- An entire OSPF domain should be under common administration.

## Network Address Translation (NAT)

- Beware of misconfiguring the IP Pool range. Double-check the start and end IPs of each IP pool. The IP pool should not overlap with addresses assigned to FortiGate interfaces or to any hosts on directly connected networks.
- If you have internal and external users accessing the same servers, use split DNS to offer an internal IP to internal users so that they don't have to use the external-facing VIP.

### Configuring NAT

Do not enable NAT for inbound traffic unless it is required by an application. If, for example, NAT is enabled for inbound SMTP traffic, the SMTP server might act as an open relay.

## Transparent Mode

- Do not connect two ports to the same VLAN on a switch or to the same hub. Some Layer 2 switches become unstable when they detect the same MAC address originating on more than one switch interface or from more than one VLAN.
- If you operate multiple VLANs on your FortiGate unit, assign each VLAN id to its own forwarding domain to ensure that the scope of the broadcast does not extend beyond the VLAN it originated in.

### To protect against Layer 2 loops:

- Enable `stpforward` on all interfaces.
- Use separate VDOMs for production traffic (TP mode VDOM) and management traffic (NAT/Route mode VDOM).
- Only place those interfaces used for production in the TP mode VDOM. Place all other interfaces in the NAT/Route mode VDOM. This protects against potential Layer 2 loops.

## Using Virtual IPs (VIPs)

- Use the external IP of 0.0.0.0 when creating a VIP for a FortiGate unit where the external interface IP address is dynamically assigned.
- Be sure to select the correct external interface when creating a new virtual IP (VIP). The external interface should be set to the interface at which the FortiGate unit receives connection requests from external networks.

## FGCP High Availability

Fortinet suggests the following practices related to high availability:

- Use Active-Active HA to distribute TCP and UTM sessions among multiple cluster units. An active-active cluster may have higher throughput than a standalone FortiGate unit or than an active-passive cluster.
- Use a different host name on each FortiGate unit when configuring an HA cluster. Fewer steps are required to add host names to each cluster unit before configuring HA and forming a cluster.
- Consider adding an Alias to the interfaces used for the HA heartbeat so that you always get a reminder about what these interfaces are being used for.
- Enabling `load-balance-all` can increase device and network load since more traffic is load-balanced. This may be appropriate for use in a deployment using the firewall capabilities of the FortiGate unit and IPS but no other content inspection.
- An advantage of using session pickup is that non-content inspection sessions will be picked up by the new primary unit after a failover. The disadvantage is that the cluster generates more heartbeat traffic to support session pickup as a larger portion of the session table must be synchronized. Session pickup should be configured only when required and is not recommended for use with SOHO FortiGate models. Session pickup should only be used if the primary heartbeat link is dedicated (otherwise the additional HA heartbeat traffic could affect network performance).
- If session pickup is not selected, after a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Users downloading large files may have to restart their download after a failover. Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.
- If you need to enable session pickup, consider enabling `session-pickup-delay` to improve performance by reducing the number of sessions that are synchronized. See [Improving session synchronization performance on page 1](#).
- Consider using the `session-sync-dev` option to move session synchronization traffic off the HA heartbeat link to one or more dedicated session synchronization interfaces. See [Improving session synchronization performance on page 1](#).
- To avoid unpredictable results, when you connect a switch to multiple redundant or aggregate interfaces in an active-passive cluster you should configure separate redundant or aggregate interfaces on the switch; one for each cluster unit.
- Use SNMP, syslog, or email alerts to monitor a cluster for failover messages. Alert messages about cluster failovers may help find and diagnose network problems quickly and efficiently.

## Heartbeat interfaces

Fortinet suggests the following practices related to heartbeat interfaces:

Do not use a FortiGate switch port for the HA heartbeat traffic. This configuration is not supported.

- Configure at least two heartbeat interfaces and set these interfaces to have different priorities.
- For clusters of two FortiGate units, as much as possible, heartbeat interfaces should be directly connected using patch cables (without involving other network equipment such as switches). If switches have to be used they should not be used for other network traffic that could flood the switches and cause heartbeat delays.
  - If you cannot use a dedicated switch, the use of a dedicated VLAN can help limit the broadcast domain to protect the heartbeat traffic and the bandwidth it creates.
- For clusters of three or four FortiGate units, use switches to connect heartbeat interfaces. The corresponding heartbeat interface of each FortiGate unit in the cluster must be connected to the same switch. For improved redundancy use a different switch for each heartbeat interface. In that way if the switch connecting one of the heartbeat interfaces fails or is unplugged, heartbeat traffic can continue on the other heartbeat interfaces and switch.
- Isolate heartbeat interfaces from user networks. Heartbeat packets contain sensitive cluster configuration information and can consume a considerable amount of network bandwidth. If the cluster consists of two FortiGate units, connect the heartbeat interfaces directly using a crossover cable or a regular Ethernet cable. For clusters with more than two units, connect heartbeat interfaces to a separate switch that is not connected to any network.
- If heartbeat traffic cannot be isolated from user networks, enable heartbeat message encryption and authentication to protect cluster information. See [Enabling or disabling HA heartbeat encryption and authentication on page 1761](#).
- Configure and connect redundant heartbeat interfaces so that if one heartbeat interface fails or becomes disconnected, HA heartbeat traffic can continue to be transmitted using the backup heartbeat interface. If heartbeat communication fails, all cluster members will think they are the primary unit resulting in multiple devices on the network with the same IP addresses and MAC addresses (condition referred to as *Split Brain*) and communication will be disrupted until heartbeat communication can be reestablished.
- Do not monitor dedicated heartbeat interfaces; monitor those interfaces whose failure should trigger a device failover.
- Where possible at least one heartbeat interface should not be connected to an NP4 or NP6 processor to avoid NP4 or NP6-related problems from affecting heartbeat traffic.
- Where possible, the heartbeat interfaces should not be connected to an NP4 or NP6 processor that is also processing network traffic.
- Where possible, each heartbeat interface should be connected to a different NP4 or NP6 processor.
- Any FortiGate interface can be used as a heartbeat interface including 10/100/1000Base-T, SFP, QSFP fiber and copper, and so on. If you set up two or more interfaces as heartbeat interfaces each interface can be a different type and speed.

## Interface monitoring (port monitoring)

Fortinet suggests the following practices related to interface monitoring (also called port monitoring):

- Wait until a cluster is up and running and all interfaces are connected before enabling interface monitoring. A monitored interface can easily become disconnected during initial setup and cause failovers to occur before the cluster is fully configured and tested.
- Monitor interfaces connected to networks that process high priority traffic so that the cluster maintains connections to these networks if a failure occurs.
- Avoid configuring interface monitoring for all interfaces.
- Supplement interface monitoring with remote link failover. Configure remote link failover to maintain packet flow if a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails. See [Remote link failover on page 1787](#).

## WAN Optimization

WAN Optimization features require significant memory resources and generate a high amount of I/O on disk. Before enabling WAN Optimization, ensure that the memory usage is not too high. If possible, avoid other disk-intensive features such as heavy traffic logging on the same disk as the one configured for WAN Optimization needs.

In general, it is preferable to enable the Transparent Mode checkbox and ensure that routing between the two endpoints is acceptable. Some protocols may not work well without enabling Transparent Mode.

Other best practices for utilizing the WAN Optimization feature follow.

### Sharing the WAN Opt. tunnel for traffic of the same nature

WAN optimization tunnel sharing is recommended for similar types of WAN optimization traffic (such as CIFS traffic from different servers). However, tunnel sharing for different types of traffic is not recommended. For example, aggressive and non-aggressive protocols should not share the same tunnel.

### Ordering WAN Opt. rules appropriately

- Precise, port specific WAN Optimization rules should be at the top of the list.
- Generic rules, such as overall TCP, should be at the bottom of the list.

### Avoiding mixing protocols in a WAN Opt. tunnel

Different protocols may be more or less talkative or interactive. Mixing protocols in a tunnel may result in a delay for some of them. It is recommended to define protocol specific wan-optimization rules and restrict the ports to the necessary ones only for performance reasons.

### Setting correct configuration options for CIFS WAN Opt.

Ensure that the WAN Optimization rules cover TCP ports 139 and 445 (on the same or two different rules). Also ensure that Transparent Mode is selected.

### Setting correct configuration options for MAPI WAN Opt.

For MAPI WAN Optimization, only specify a rule with TCP port 135 (unless the MAPI control port is configured differently). Derived data sessions using other random ports will be handled by the CIFS wan-optimization daemon even with only the control port configured.

### Testing WAN Opt. in a lab

- Ensure that WAN emulators are used to simulate the WAN. If no WAN emulator is used, it is expected to have better results without WAN Optimization than with WAN Optimization.
- To test the difference between cold transfers (first-time transfers) and warm transfers, it is recommended to generate a random file of the cold transfer to ensure that the test is the first time that the file has been seen.

### **Regarding byte compression and type of file**

Enabling byte compression on file transfers already compressed (.jpeg files, compressed archive, etc.) won't provide any performance increase and could be seen as a misuse of CPU resources.

### **Regarding network address translation (NAT)**

Selecting the NAT feature in a security policy does not have any influence on WAN Optimization traffic.

### **High Availability**

There is no benefit to using active-active mode, so for pure WAN Optimization needs, use active-passive mode. Refer to the [FGCP High Availability](#) section for other best practices related to HA.

### **Authentication with specific peers**

Configure WAN optimization authentication with specific peers. Accepting any peer is not recommended as this can be less secure.

## Virtual Domains (VDOMs)

VDOMs can provide separate firewall policies and, in NAT/Route mode, completely separate configurations for routing and VPN services for each connected network or organization. This section provides a list of best practices for configuring VDOMs.

### Per-VDOM resource settings

While Global resources apply to resources shared by the whole FortiGate unit, per-VDOM resources are specific to only one Virtual Domain.

By default all the per-VDOM resource settings are set to no limits. This means that any single VDOM can use up all the resources of the entire FortiGate unit if it needs to do so. This would starve the other VDOMs for resources to the point where they would be unable to function. For this reason, it is recommended that you set some maximums on resources that are most vital to your customers.

### Virtual domains in NAT/Route mode

Once you have enabled virtual domains and created one or more VDOMs, you need to configure them. It is recommended that you perform the following tasks in the order given (while you may not require all for your network topology):

1. Change the management virtual domain.
2. Configure FortiGate interfaces in a NAT/Route VDOM.
3. Configure VDOM routing.
4. Configure security policies for NAT/Route VDOMs.
5. Configure UTM profiles for NAT/Route VDOMs.
6. Test the configuration.

### Virtual clustering

If you decide to disable override for clustering, as a result of persistent renegotiating, you should disable it for both cluster units.

## Explicit proxy

- For explicit proxies, when configuring limits on the number of concurrent users, you need to allow for the number of users based on their authentication method. Otherwise you may run out of user resources prematurely.
- Each session-based authenticated user is counted as a single user using their authentication membership (RADIUS, LDAP, FSSO, local database etc.) to match users in other sessions. So one authenticated user in multiple sessions is still one user.
- For all other situations, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.
- Set the explicit web proxy and explicit FTP proxy Default Firewall Policy Action to Deny. This means that a firewall policy is required to use these explicit proxies, allowing you to control access and impose security features.
- Do not enable the explicit web or FTP proxy on an interface connected to the Internet. This is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you must enable the proxy on such an interface make sure authentication is required to use the proxy.

## Wireless

The following section contains a list of best practices for wireless network configurations with regard to encryption and authentication, geographic location, network planning, power usage, client load balancing, local bridging, SSIDs, and the use of static IPs.

### Encryption and authentication

It is best practice to always enable the strongest user authentication and encryption method that your client supports. Fortinet recommends the following security, in order of strongest to weakest:

- WPA2 - Enterprise 802.1x/EAP - Personal pre-shared key (8-63 characters)
- WPA - Enterprise 802.1x/EAP - Personal pre-shared key (8-63 characters)
- WEP128 - 26 Hexadecimal digit key
- WEP64 - 10 Hexadecimal digit key
- None - Open system

### Geographic location

Ensure that the FortiGate wireless controller is configured for your geographic location. This ensures that the available radio channels and radio power are in compliance with the regulations in your region.

The maximum allowed transmitter power and permitted radio channels for Wi-Fi networks depend on the region in which the network is located. By default, the WiFi controller is configured for the United States. If you are located in any other region, you need to set your location before you begin configuring wireless networks.

The location setting can only be changed from CLI. To change the country to France, for example, enter the following:

```
config wireless-controller setting
  set country FR
end
```

To see the list of country codes, enter a question mark ('?') in place of the country code.

Using an incorrect geographic location is a common error that can lead to unpredictable results on the client side.

### Network planning

It is recommended that you perform a proper site survey prior positioning the wireless access point. In order to evaluate the coverage area environment, the following criteria must be taken into account:

- Size of coverage area
- Bandwidth required
- Client wireless capabilities

After completing a RF site survey, you'll have a good idea of the number and location of access points needed to provide users with adequate coverage and performance.

However, prior to installing the access points, be sure to determine the RF channel(s) you plan to use. This will ensure that users can roam throughout the facility with substantial performance.

To avoid co-channel interference, adjacent Wi-Fi APs must be configured to use non-overlapping channels. Otherwise, you'll find poor performance will degrade because of interference between access points.

It is recommended to statically configure the non-overlapping channels on every access point, using one Custom AP profile per AP (or group of APs). If static configuration cannot be used, the FortiOS Wi-Fi Controller includes the Automatic Radio Resource Provisioning (ARRP) feature.

## Lowering the power level to reduce RF interference

**Relevant Product(s):** FortiAP

Reducing power reduces unwanted coverage and potential interference to other WLANs. Areas of unwanted coverage are a potential security risk. If possible, reduce the transmitter power of your wireless access point so that the signal is not available beyond the areas where it is needed. Auto Tx Power Control can be enabled to automatically adjust the transmit power.

In cases where customers complain about slow wireless traffic through a FortiAP, it might be necessary to try to reduce the possibility of RF interference. It is best practice not to locate FortiAPs near steel beams or other interfering materials. You can try using a wireless sniffer tool to collect the wireless packets and then analyze the extent of air interference.

A common mistake is spacing FortiAPs based upon the 5Ghz radio frequency. The 2.4Ghz signal travels further.

You have two options when confronted with slow wireless traffic through a FortiAP:

### Option #1: Reducing transmit power

Perform a speed test and record the results. Set one of the radios on a FortiAP to be in dedicated monitoring mode. Then observe how many APs are detected. If the number of APs is too high (i.e., greater than 20), try reducing the transmit power in the WTP profile for the FortiAPs until the number of dedicated APs has dropped significantly.

Repeat the speed test.

### Option #2: Ensuring that VAPs are distributed over the available channels

No built-in tools are available to measure RF interference directly. However, FortiOS 5.0 does allow for automatic power adjustment, which should minimize the occurrence of RF interference.

## Wireless client load balancing

Wireless load balancing allows your wireless network to more efficiently distribute wireless traffic among wireless access points and available frequency bands. FortiGate wireless controllers support the following types of client load balancing:

- **Access Point Hand-off** - The wireless controller signals a client to switch to another access point.
- **Frequency Hand-off** - The wireless controller monitors the usage of 2.4GHz and 5GHz bands, and signals clients to switch to the lesser-used frequency.

## Local bridging

Whenever possible, use local bridging to offload the CAPWAP tunnel. Note that in this case, Wi-Fi client devices obtain IP addresses from the same DHCP server as wired devices on the LAN. The vlan ID can only be configured

from the CLI:

```
config wireless-controller vap
  edit "vaplocalbridge"
    set vdom "root"
    set ssid "testvaplocalbridge"
    set local-bridging enable
    set vlanid 40 ---> only available in CLI
  next
end
```

## Advertising SSIDs

- It is highly recommended to advertise the SSID. It makes it easier for customers and wireless clients. Also, if you 'hide' the SSID (known as 'network cloaking'), then clients will always look for it when they're outside the coverage area, which searches for known SSIDs, in effect leaking the SSID anyway. Refer to [RFC 3370](#). Furthermore, many of the latest Broadcom drivers do not support hidden SSID for WPA2.
- For security reason, you might want to prevent direct communication between your wireless clients. In this case, enable Block Intra-SSID Traffic (in the SSID configuration).
- In a network with multiple wireless controllers, you need to change the mesh SSID so that each mesh root has a unique SSID. Other controllers using the same mesh root SSID might be detected as fake or rogue APs. Go to **WiFi & Switch Controller > SSID** to change the SSID. Fortinet also recommends that you create a new preshared key instead of using the default.

## Using static IPs in a CAPWAP configuration

In a large FortiAP deployment with more than 20 FortiAPs connecting to a Fortigate Wireless Controller (AC), it is recommended to use static IPs on the access points instead of DHCP, setting the AC IP statically and the AC discovery type to static (Type 1), instead of learning it through broadcast, multicast, or DHCP.

This makes management of the APs easier since you know the exact IP of each access point. Troubleshooting also becomes easier as the debug of the AC controller won't continuously attempt the different discovery methods in sequence (broadcast > multicast > static).

## Logging and reporting

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled, except for traffic logging. The default logging location will be either the FortiGate unit's system memory or hard disk, depending on the model. Units with a flash disk are not recommended for disk logging.

### Log management

When the FortiGate unit records FortiGate activity, valuable information is collected that provides insight into how to better protect network traffic against attacks, including misuse and abuse. There is a lot to consider before enabling logging on a FortiGate unit, such as what FortiGate activities to enable and which log device is best suited for your network's logging needs. A plan can help you in deciding the FortiGate activities to log, a log device, as well as a backup solution in the event the log device fails.

This plan should provide you with an outline, similar to the following:

- What FortiGate activities you want and/or need logged (for example, security features).
- The logging device best suited for your network structure.
- If you want or require archiving of log files.
- Ensuring logs are not lost in the event a failure occurs.

After the plan is implemented, you need to manage the logs and be prepared to expand on your log setup when the current logging requirements are outgrown. Good log management practices help you with these tasks.

Log management practices help you to improve and manage logging requirements. Logging is an ever-expanding tool that can seem to be a daunting task to manage. The following management practices will help you when issues arise, or your logging setup needs to be expanded.

- Revisit your plan on a yearly basis to verify that your logging needs are being met by your current log setup. For example, your company or organization may require archival logging, but not at the beginning of your network's lifespan. Archival logs are stored on a FortiGate unit's local hard drive, a FortiAnalyzer unit, or a FortiCloud server, in increasing order of size.
- Configure an alert message that will notify you of activities that are important to be aware about. For example: if a branch office does not have a FortiGate administrator, you will need to know at all times that the IPsec VPN tunnel is still up and running. An alert email notification message can be configured to send only if IPsec tunnel errors occur.
- If your organization or company uses peer-to-peer programs such as Skype or other instant messaging software, use the IM usage dashboard widget or the Executive Summary's report widget (Top 10 Application Bandwidth Usage Per Hour Summary) to help you monitor the usage of these types of instant messaging software. These widgets can help you in determining how these applications are being used, including if there is any misuse and abuse. Their information is taken from application log messages; however, application log messages should be viewed as well since they contain the most detailed information.
- Ensure that your backup solution is up-to-date. If you have recently expanded your log setup, you should also review your backup solution. The backup solution provides a way to ensure that all logs are not lost in the event that the log device fails or issues arise with the log device itself.

- When downloading log messages and viewing them on a computer, the log file will be downloaded like any other file. Log file names contain their log type and date in the name, so it is recommended to create a folder in which to archive your log messages, as they can be sorted easily.

## System memory and hard disks

If the FortiGate unit has a hard disk, it is enabled by default to store logs. This also means that you do not have to enable this and configure the settings for logging to the hard disk, but modify these settings so that it is configured for your network logging requirements.

If the FortiGate unit has only flash memory, disk logging is disabled by default, as it is not recommended. Constant rewrites to flash drives can reduce the lifetime and efficiency of the memory. It must be enabled in the CLI under config log disk setting.

For some low-end models, disk logging is unavailable. Check a product's Feature Matrix for more information. In either case, Fortinet recommends using either a FortiAnalyzer unit or the FortiCloud service.

## Chapter 5 - FortiOS Carrier

This FortiOS Handbook chapter contains the following sections:

- [What's New in FortiOS 5.6](#)
  - Features and improvements that have been added in version FortiOS 5.6
- [Overview of FortiOS Carrier features](#)
  - The high altitude overview of FortiOS Carrier
- ["MMS Concepts" on page 615](#)
  - Basic background on MMS and its concepts so that there is some context to the settings used in the MMS configuration
- ["MMS Configuration" on page 630](#)
  - Listing of the MMS configuration options and settings
  - Procedures and insights in the configuration of the MMS components of FortiOS Carrier
- [GTP basic concepts](#)
  - Basic background on GTP and its concepts so that there is some context to the settings used in the GTP configuration
- ["GTP Configuration" on page 695](#)
  - Listing of the GTP configuration options and settings
  - Procedures and insights in the configuration of the GTP components of FortiOS Carrier
- ["SCTP Concepts" on page 737](#)
  - Background on SCTP, and how it makes the FortiOS Carrier different than the FortiGate
- ["Troubleshooting" on page 741](#)
  - Some basic procedures for troubleshooting FortiOS Carrier

## What's New in FortiOS 5.6

### New features added in 5.6.3

#### Improved CLI attribute name under 'gtp.message-filter-v0v1' (452813)

CLI "gtp.message-filter-v0v1" had an attribute "create-aa-pdp|init-pdp-ctx", which contains a vertical pipe |. The attribute name was changed to "v0-create-aa-pdp--v1-init-pdp-ctx".

Its help text is also changed to avoid the vertical bar.

#### Syntax

```
config gtp message-filter-v0v1
  edit <name>
    set ?
    .....
    v0-create-aa-pdp--v1-init-pdp-ctx
```

## Improved GTP performance (423332)

There are independent Receive and Transmit queues for `gtp-u` process. These queues are and their associated resources are initialized when the `ftp-enhance-mode` is enabled.

### CLI changes under `system npu`

#### `gtp-enhance-mode`

```
config system npu
  set gtp-enhance-mode [enable|disable]
end
```

This configuration requires a reboot of the device to initialize the changes.

#### `gtp-enhance-cpu-range`

This is used to set the CPUs which can process the GTP-U packet inspection.

```
config system npu
  set gtp-enhance-cpu-range [0|1|2]
end
```

Option	Description
0	Inspect GTPU packets by all CPUs
1	Inspect GTPU packets by Master CPUs
2	Inspect GTPU packets by Slave CPUs

### New diagnose commands

```
diagnose npu np6 hbq-stats [all|np xx]
```

Used to see the GTP-U packet counter by all NP or the corresponding np.

```
diagnose npu np6 hbq-stats-clear all /np xx
```

Used to clear the GTP-U packet counter by all NP or the corresponding np.

### Verifying the enhance-mode is disabled

Before execute the test or enable/disable the gtp enhance, first check the `gtp-enhance-mode` status as in the example below:

```
config system npu
  get
  gtp-enhance-mode: disable
  gtp-enhance-cpu-range: 0
end
```

If the `gtp-enhance-mode` is `disable`, use the command `diagnose npu np6 hbq-stats all`.

The output will be similar to below:

```
# diagnose npu np6 hbq-stats all
Total :0
```

If the `gtp-enhance-mode` is enable, use the command `diagnose npu np6 hbq-stats all`

The output will be similar to below:

```
# diagnose npu np6 hbq-stats all
cpu_ 0:0
cpu_ 1:0
cpu_ 2:0
cpu_ 3:0
cpu_ 4:0
cpu_ 5:0
cpu_ 6:0
cpu_ 7:0
cpu_ 8:0
cpu_ 9:0
cpu_10:0
cpu_11:0
cpu_12:0
cpu_13:0
cpu_14:0
cpu_15:0
cpu_16:0
cpu_17:0
cpu_18:0
cpu_19:0
cpu_20:0
cpu_21:0
cpu_22:0
cpu_23:0
cpu_24:0
cpu_25:0
cpu_26:0
cpu_27:0
cpu_28:0
cpu_29:0
cpu_30:0
cpu_31:0
cpu_32:0
cpu_33:0
cpu_34:0
cpu_35:0
cpu_36:0
cpu_37:0
cpu_38:0
cpu_39:0
Total :0
```

Sometimes, when loading the new configure file, and the new configure file does not match the old configure file, the `gtp-enhance-mode` status will be confused.

You can see :

```
#config system npu
#get
gtp-enhance-mode: enable
```

but you can also see that

```
diagnose npu np6 hbq-stats all
Total :0
```

This means the `gtp-enhance-mode` is actually set to `disable`.

The inverse is also possible, when you see

```
#config system npu
#get
gtp-enhance-mode: disable
```

but you also see that

```
# diagnose npu np6 hbq-stats all
cpu_ 0:0
...
cpu_39:0
Total :0
```

This means the `gtp-enhance-mode` is actually set to `enable`.

If these combinations occur, just run the command below:

```
config system npu
  set gtp-enhance-mode enable
end
```

or

```
config system npu
  set gtp-enhance-mode disable
end
```

Once this is done, reboot the device to let the 2 statuses match.

## New features added in 5.6.1

### GTP enhancement and GTP Performance Improvement. (423332)

The GTP changes in 5.6.1 take place in the following categories:

#### New GTP features and functionality enhancements.

- GTP message filter enhancements, including:
  - Unknown message white list
  - GTPv1 and GTPv2 profile separation
  - Message adoption.
- GTP IE white list.
- Global APN rate limit, including:

- sending back REJECT message with back-off timer
- "APN congestion" cause value
- GTP half-open, half-close configurable timer.

### GTP performance improvements.

- Implemented RCU on GTP-U running path. i.e, no locking needed to look up tunnel state when processing GTP-U.

**Note** the RCU is only applied on GTPv1 and GTPv2 tunnels. It is not used for GTPv0 tunnels, due to the fact that (1) GTPv0 traffic is relatively minor compared with GTPv1 and GTPv2, and (2) GTPv0 tunnel indexing is totally different from GTPv1 and GTPv2. GTPv0 tunnel is indexed by [IMSI, NSAPI]. GTPv1 and GTPv2 tunnel is indexed by [IP, TEID]

- Localized CPU memory usage on GTP-U running path.
- GTP-C: changed some GTP tables from RB tree to hash table, including
  - GTP request tables, and GTPv0 tunnel tables.
  - Testing showed, when handling millions of entries adding/deleting, hash table performance was much better.
  - 2.3.2 Hash table is compatible with RCU API, so we can apply RCU on these GTP-C tables later for further performance improvements.
- GTP-C, improved GTP path management logic, so that GTP path will time out sooner when there are no tunnels linked to it

### CLI Changes:

#### New Diagnose commands:

```
diagnose firewall gtp
```

Option	Description
hash-stat-tunnel	GTP tunnel hash statistics.
hash-stat-v0tunnel	GTPv0 tunnel hash statistics.
hash-stat-path	GTP path hash statistics.
hash-stat-req	GTP request hash statistics.
vd-apn-shaper	APN shaper on VDOM level.
ie-white-list-v0v1	IE white list for GTPv0 or v1.
ie-white-list-v2	IE white list for GTPv2.

```
diagnose firewall gtp vd-apn-shaper
```

Option	Description
list	List

```
diagnose firewall gtp ie-white-list-v0v1
```

Option	Description
list	List

```
diagnose firewall gtp ie-white-list-v2
```

Option	Description
list	List

```
config gtp apn-shaperapn-shaper
```

Option	Description
apn	APN to match. Leave empty to match ANY.  "apn" field can be empty, it matches ANY apn. when configured, it is used to set a limit for any apn which is not explicitly listed; Also, if configured, such an entry should be the last entry, as it is first-match rule.
rate-limit	Rate limit in packets/s (0 - 1000000, 0 means unlimited).
action	Action. [drop   reject]  There is no back-off timer in GTPv0, therefor the <code>reject</code> action is not available for V0
back-off-time	Back off time in seconds (10 - 360).  <code>back-off-time</code> visible when action is "reject"

### Changed commands:

Under command `firewall gtp`, `config message-filter` is replaced by `set message-filter-v0v1`

### Example:

```
config firewall gtp
edit <name>
set message-filter-v0v1
```

New fields have been added to the `config firewall gtp` command context

Option	Description
half-open-timeout	Half-open tunnel timeout (in seconds).
half-close-timeout	Half-close tunnel timeout (in seconds).

**Example:**

```
config firewall gtp
  edit <name>
    set half-open-timeout 10
    set half-close-timeout 10
```

**Models affected by change**

- FortiGate 3700D
- FortiGate 3700DX
- FortiGate 3800D

## Overview of FortiOS Carrier features

FortiOS Carrier specific features include Multimedia messaging service (MMS) protection, and GPRS Tunneling Protocol (GTP) protection.

All FortiGate units, carrier-enabled or not, are capable of handling Stream Control Transmission Protocol (SCTP) traffic, which is a protocol designed for and primarily used in Carrier networks.

This section includes:

### Overview

FortiOS Carrier provides all the features found on FortiGate units plus added features specific to carrier networks: MMS and GTP.

### MMS

MMS is a standard for sending messages that include multimedia content between mobile phones. MMS is also popular as a method of delivering news and entertainment content including videos, pictures, and text. Carrier networks include four different MMS types of messages — MM1, MM3, MM4, and MM7.

### GTP

The GPRS Tunneling Protocol (GTP) runs on GPRS carrier networks. GPRS is a GSM packet radio standard. It provides more efficient usage of the radio interface so that mobile devices can share the same radio channel. FortiOS supports GTPv1 and GTPv2.

GPRS provides direct connections to the Internet (TCP/IP) and X.25 networks for point-to-point services (connection-less/connection oriented) and point-to-multipoint services (broadcast).

GPRS currently supports data rates from 9.6 kbps to more than 100 kbps, and it is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based) that converts the message from radio to wired, and sends the message to the carrier network and eventually the Internet (wired carrier network). See [GTP](#).

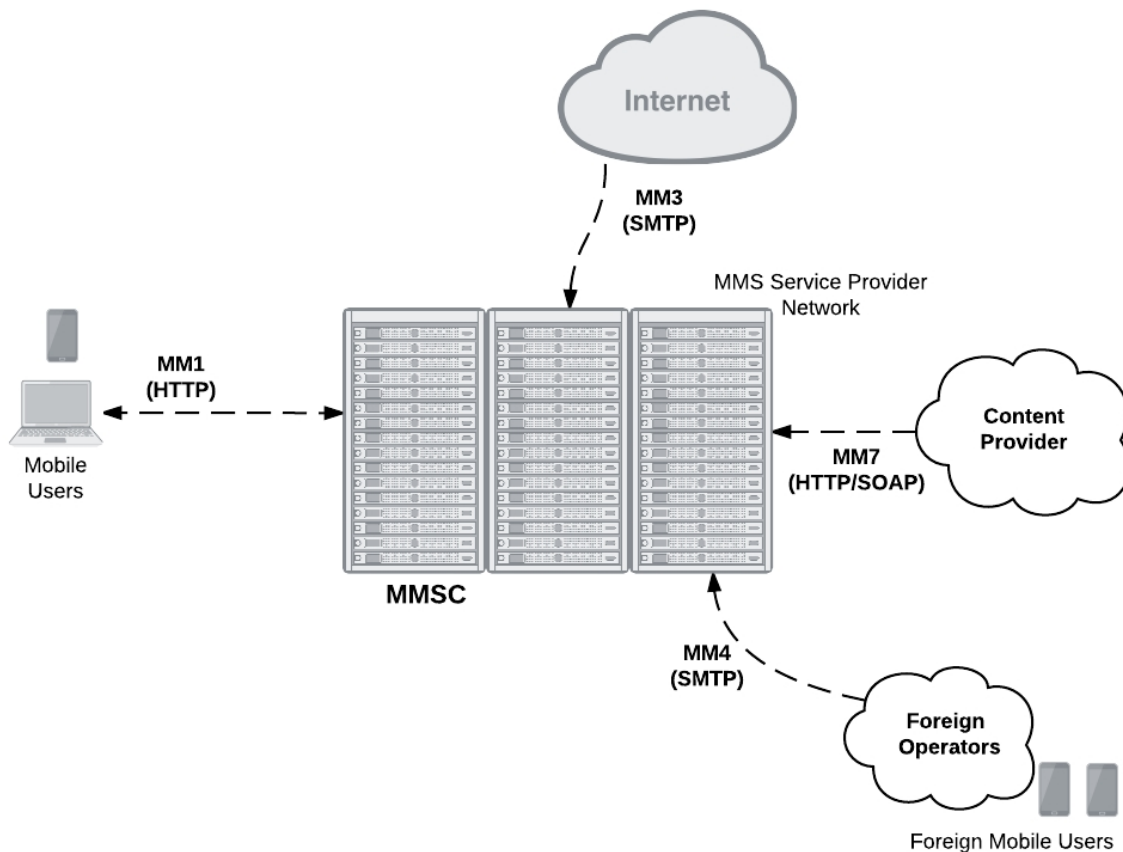

## MMS Concepts

### MMS background

MMS is a common method for mobile users to send and receive multimedia content. A Carrier network supports MMS across its network. This makes up the MMS Service Provider Network (MSPN).

Messages can be sent or received between the MMSC and a number of other services including the Internet, content providers, or other carriers. Each of these different service connections uses different MMS formats including MM1 and MM7 messages (essentially HTTP format), and MM3 and MM4 messages (SMTP formatted). These different formats reflect the different purposes and content for each type of MMS message.

## MMS content interfaces

## MMS content interfaces

MMS messages are sent from devices and servers to other devices and servers using MMS content interfaces

There are eight interfaces defined for the MMS standard, referred to as MM1 through MM8. The most important of these interfaces for the transfer of data is the MM1 interface, as this defines how mobile users communicate from the mobile network to the Multimedia Message Service Center (MMSC). MMS content to be monitored and controlled comes from these mobile users and is going to the provider network.

Other MMS content interfaces that connect a service provider network to other external sources can pose threats as well. MM3 handles communication between the Internet and the MMSC and is a possible source of viruses and other content problems from the Internet. MM4 handles communication between different content provider MMSCs. Filtering MM4 content protects the service provider network from content sent from foreign service providers and their subscribers. Finally MM7 is used for communication between content providers and the MMSC. Filtering MM3 content can also keep harmful content off of the service provider network.

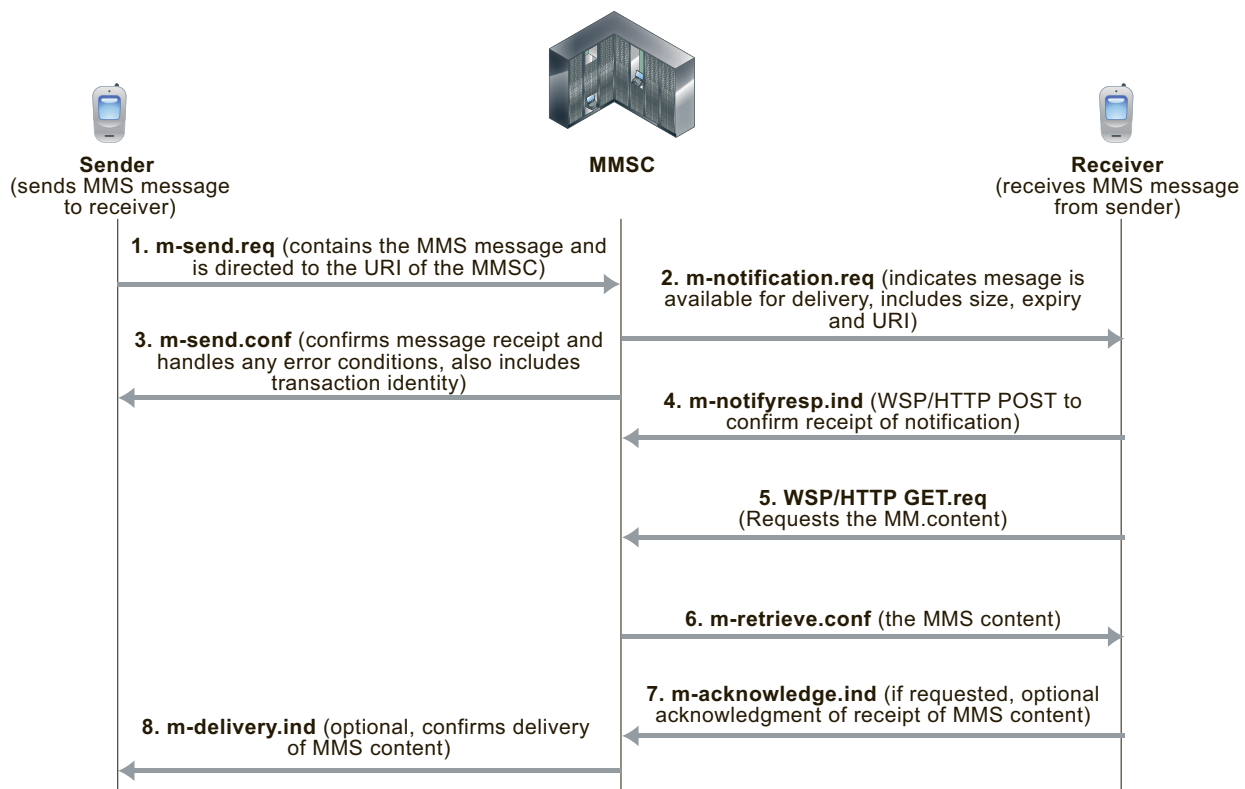

### MMS content interfaces

Type	Transaction	Similar to
MM 1	Handset to MMSC	HTTP
MM 3	Between MMSC and Internet	SMTP
MM 4	Between Operator MMSCs	SMTP
MM 7	Content Providers to MMSC	HTTP and SOAP

### How MMS content interfaces are applied

As shown below, the sender's mobile device encodes the MMS content in a form similar to MIME email message (MMS MIME content formats are defined by the MMS Message Encapsulation specification). The encoded message is then forwarded to the service provider's MMSC. Communication between the sending device and the MMSC uses the MM1 content interface. The MM1 content interface establishes a connection and sends an MM1 send request (`m-send.req`) message that contains the MMS message. The MMSC processes this request and sends back an MM1 send confirmation (`m-send.conf`) HTTP response indicating the status of the message — accepted or an error occurred, for example.

### MM1 transactions between senders and receivers and the MMSC

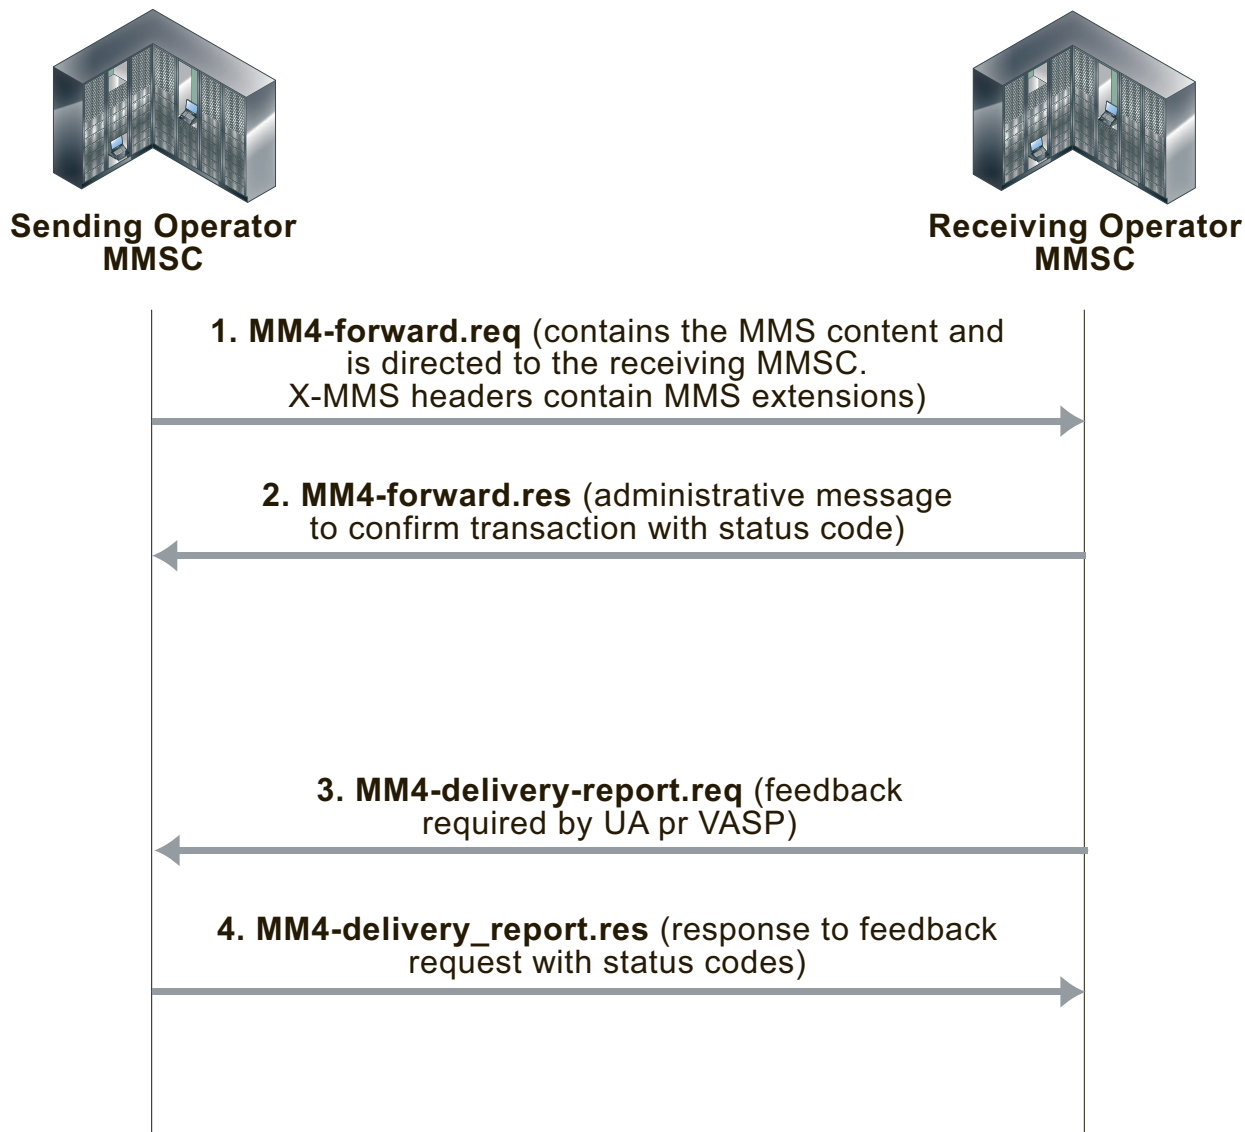

If the recipient is on another carrier, the MMSC forwards the message to the recipient's carrier. This forwarding uses the MM4 content interface for forwarding content between operator MMSCs (see the figure below).

Before the MMSC can forward the message to the final recipient, it must first determine if the receiver's handset can receive MMS messages using the MM1 content interface. If the recipient can use the MM1 content interface, the content is extracted and sent to a temporary storage server with an HTTP front-end.

To retrieve the message, the receiver's handset establishes a connection with the MMSC. An HTTP get request is then sent from the recipient to the MMSC. This message contains the URL where the content of the message is stored. The MMSC responds with a retrieve confirmation (`m-retrieve.conf`) HTTP response that contains the message.

#### MM4 messages sent between operator MMSCs

This causes the receiver's handset to retrieve the content from the embedded URL. Several messages are exchanged to indicate status of the delivery attempt. Before delivering content, some MMSCs also include a content adaptation service that attempts to modify the multimedia content into a format suitable for the recipient's handset.

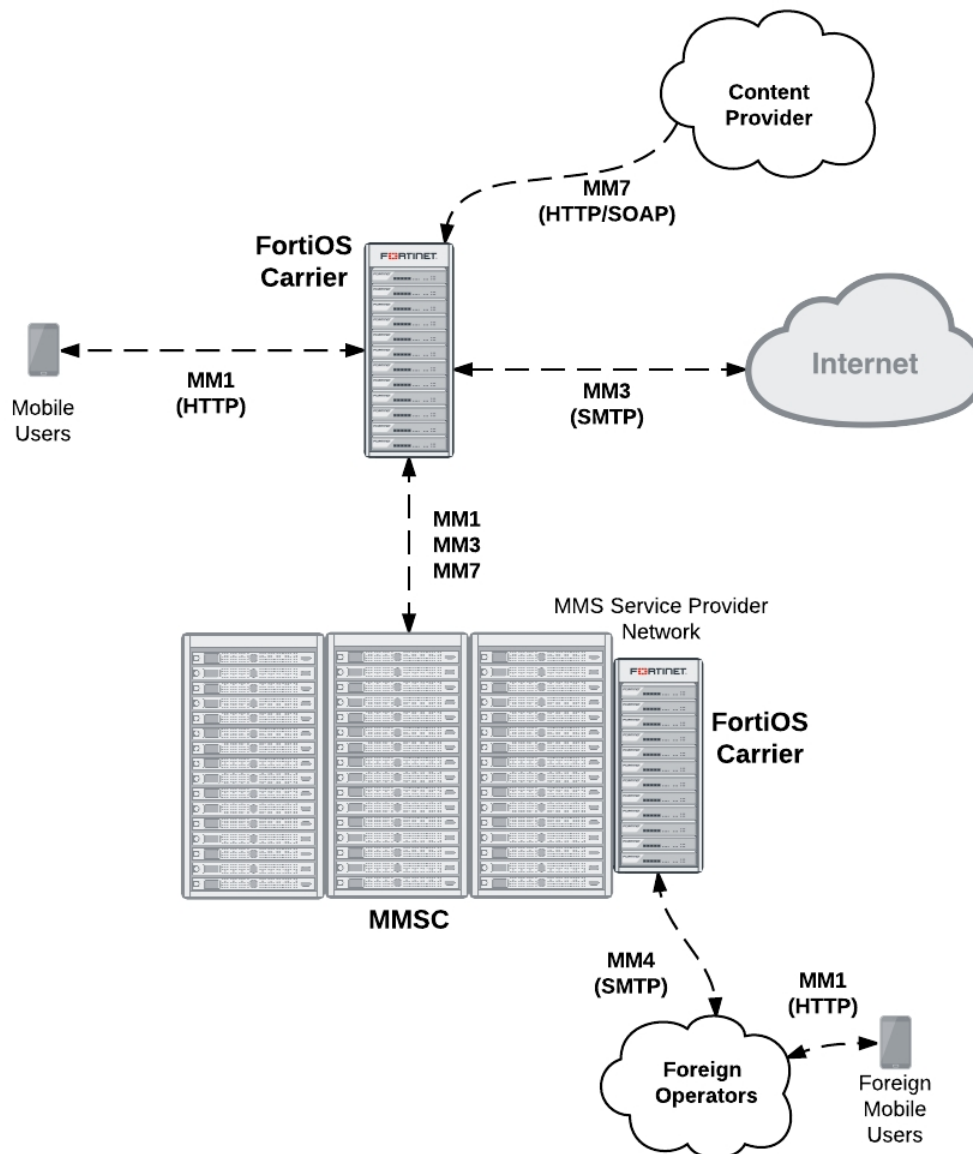

If the receiver's handset is not MM1 capable, the message can be delivered to a web based service and the receiver can view the content from a normal Internet browser. The URL for the content can be sent to the receiver in an SMS text message. Using this method, non-MM1 capable recipients can still receive MMS content.

The method for determining whether a handset is MMS capable is not specified by the standards. A database is usually maintained by the operator, and in it each mobile phone number is marked as being associated with a legacy handset or not. It can be a bit hit and miss since customers can change their handset at will and this database is not usually updated dynamically.

Email and web-based gateways from MMSC to the Internet use the MM3 content interface. On the receiving side, the content servers can typically receive service requests both from WAP and normal HTTP browsers, so delivery via the web is simple. For sending from external sources to handsets, most carriers allow MIME encoded message to be sent to the receiver's phone number with a special domain.

## How FortiOS Carrier processes MMS messages

MMS messages can be vectors for propagating undesirable content such as spam and viruses. FortiOS Carrier can scan MMS messages sent using the MM1, MM3, MM4, and MM7 content interfaces. You can configure FortiOS Carrier to scan MMS messages for spam and viruses by configuring and adding MMS protection profiles and adding the MMS protection profiles to security policies. You can also use MMS protection profiles to apply content blocking, carrier endpoint filtering, MMS address translation, sending MMS notifications, DLP archiving of MMS messages, and logging of MMS message activity.

**FortiOS Carrier MMS processing**

FortiOS Carrier can send MMS messages to senders informing those senders that their devices are infected. FortiOS Carrier can also send MMS notifications to administrators to inform them of suspicious activity on their networks.

For message floods and duplicate messages, FortiOS Carrier does not send notifications to message senders but does send notifications to administrators and sends messages to sender handsets to complete MM1 and MM4 sessions.

Where MMS messaging uses the TCP/IP set of protocols, SMS text messaging uses the Signaling System Number 7 (SS7) set of protocols, which is not supported by FortiOS.

## FortiOS Carrier and MMS content scanning

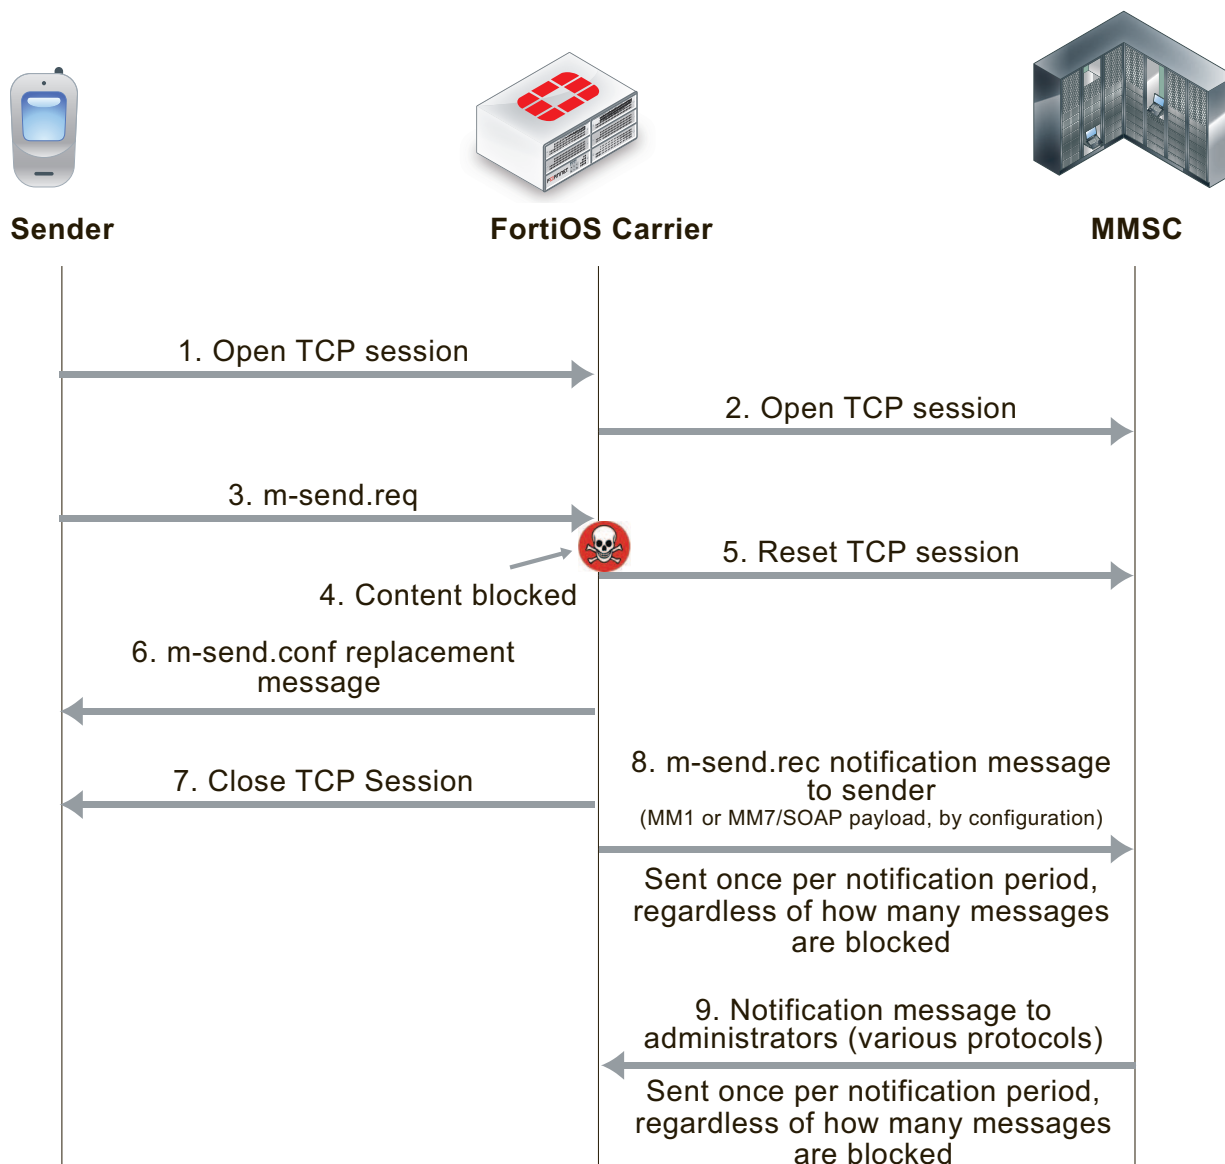

The following section applies to MMS content scanning, including virus scanning, file filtering, content spam filtering, carrier endpoint filtering, and MMS content checksum filtering.

### MM1 Content Scanning

During MM1 content scanning a message is first transmitted from the sender, establishing a connection with the MMSC. FortiOS Carrier intercepts this connection and acts as the endpoint. FortiOS Carrier then establishes its own connection to the MMSC. Once connected, the client transmits its `m-send.req` HTTP post request to FortiOS Carrier which scans it according to the MMS protection profile settings. If the content is clean, the message is forwarded to the MMSC. The MMSC returns `m-send.conf` HTTP response through FortiOS Carrier to the sender.

If FortiOS Carrier blocks the message (for example because a virus was found, see the figure below), FortiOS Carrier resets the connection to the MMSC and sends `m-send.conf` HTTP response back to the sender. The response message can be customized using replacement messages. FortiOS Carrier then terminates the connection. Sending back an `m-send.conf` message prevents the sender from trying to send the message again.

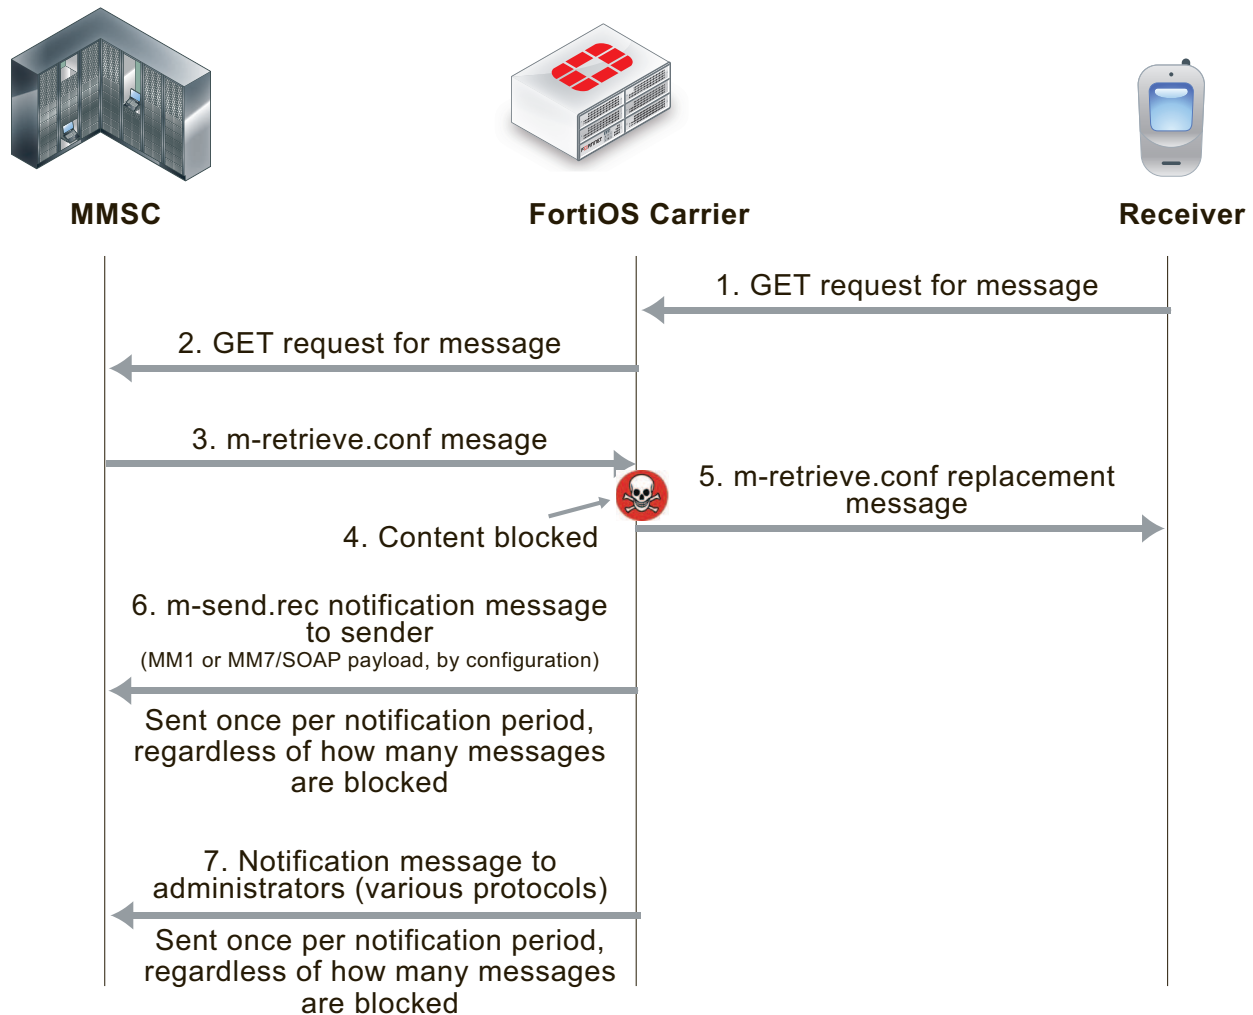

**MM1 MMS scanning of message sent by sender (blocking m.send.req messages)**

FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the sender to notify them of blocked messages.

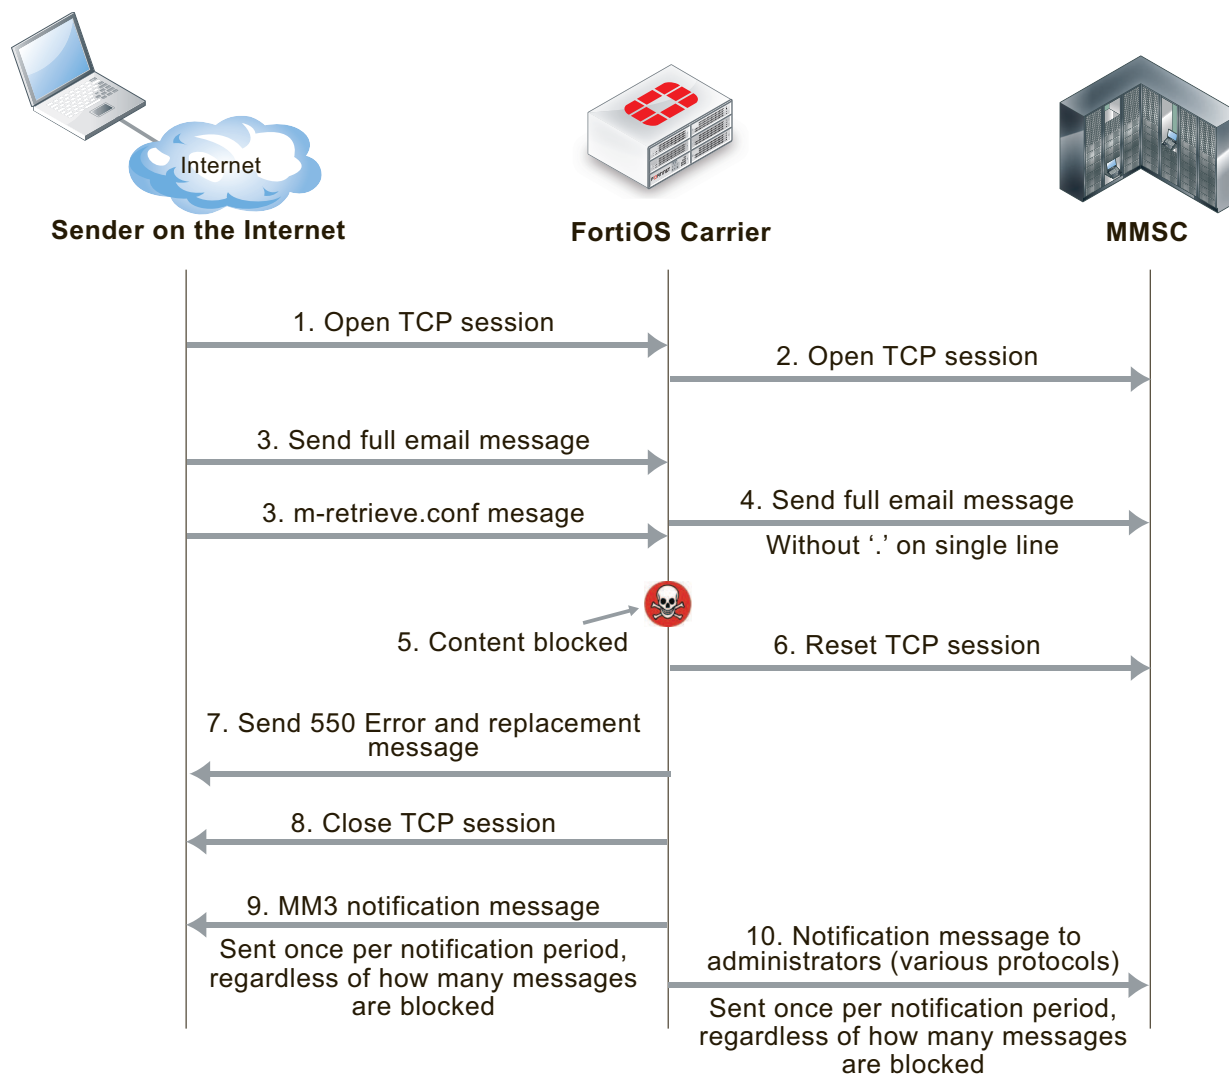

**Filtering message retrieval**

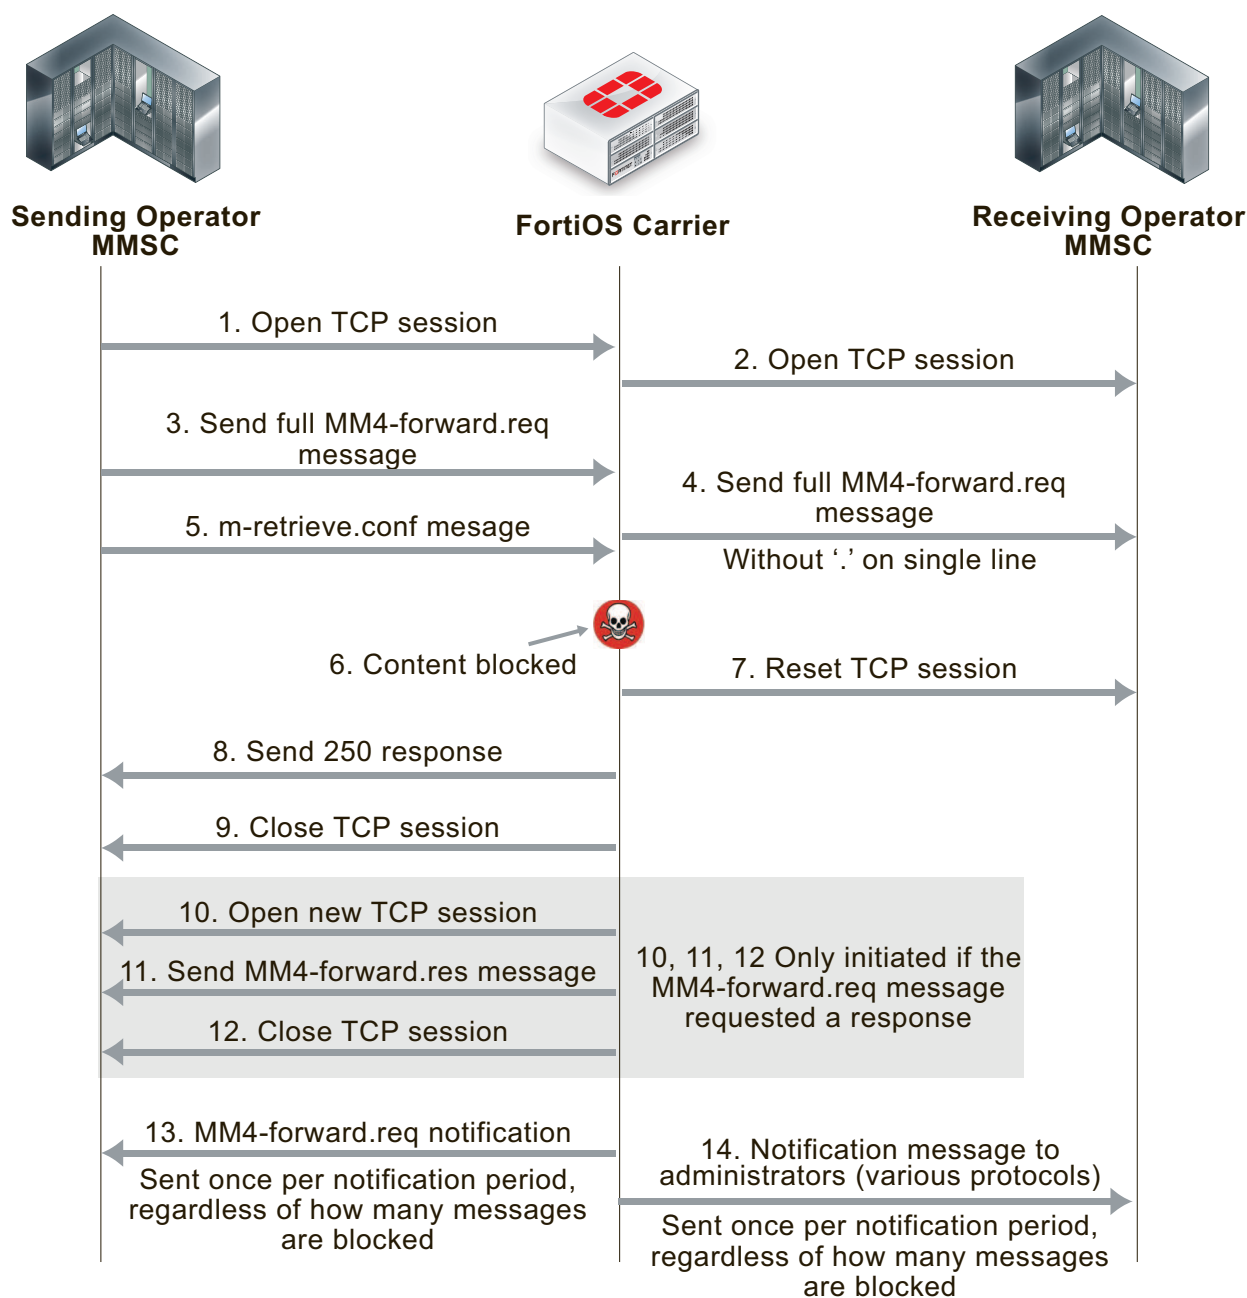

FortiOS Carrier intercepts the connection to the MMSC, and the `m-retrieve.conf` HTTP response from the MMSC is scanned according to the MMS content scanning settings. If the content is clean, the response is forwarded back to the client. If the content is blocked, FortiOS Carrier drops the connection to the MMSC. It then builds an `m-retrieve.conf` message from the associated replacement message and transmits this back to the client.

FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the receiver to notify them of blocked messages.

**MM1 MMS scanning of messages received by receiver (blocking m.retrieve.conf messages)**

Filtering MM3 and MM4 messages works in an similar way to MM1 (see the figures below). FortiOS Carrier intercepts connections to the MMSC, and scans messages as configured. When messages are blocked, FortiOS Carrier closes sessions as required, sends confirmation messages to the sender, notifies administrators, and notifies senders and receivers of messages.

**MM3 MMS scanning of messages sent from a sender on the Internet to an MMSC**

**MM4 MMS scanning of messages sent between operator MMSCs**

**MM7 MMS scanning of messages sent between a VASP and an MMSC****FortiOS Carrier and MMS duplicate messages and message floods**

FortiOS Carrier detects duplicate messages and message floods for the MM1 and MM4 interfaces. How FortiOS Carrier detects and responds to duplicate messages and message floods is different from how FortiOS Carrier detects and responds to viruses and other MMS scanning protection measures.

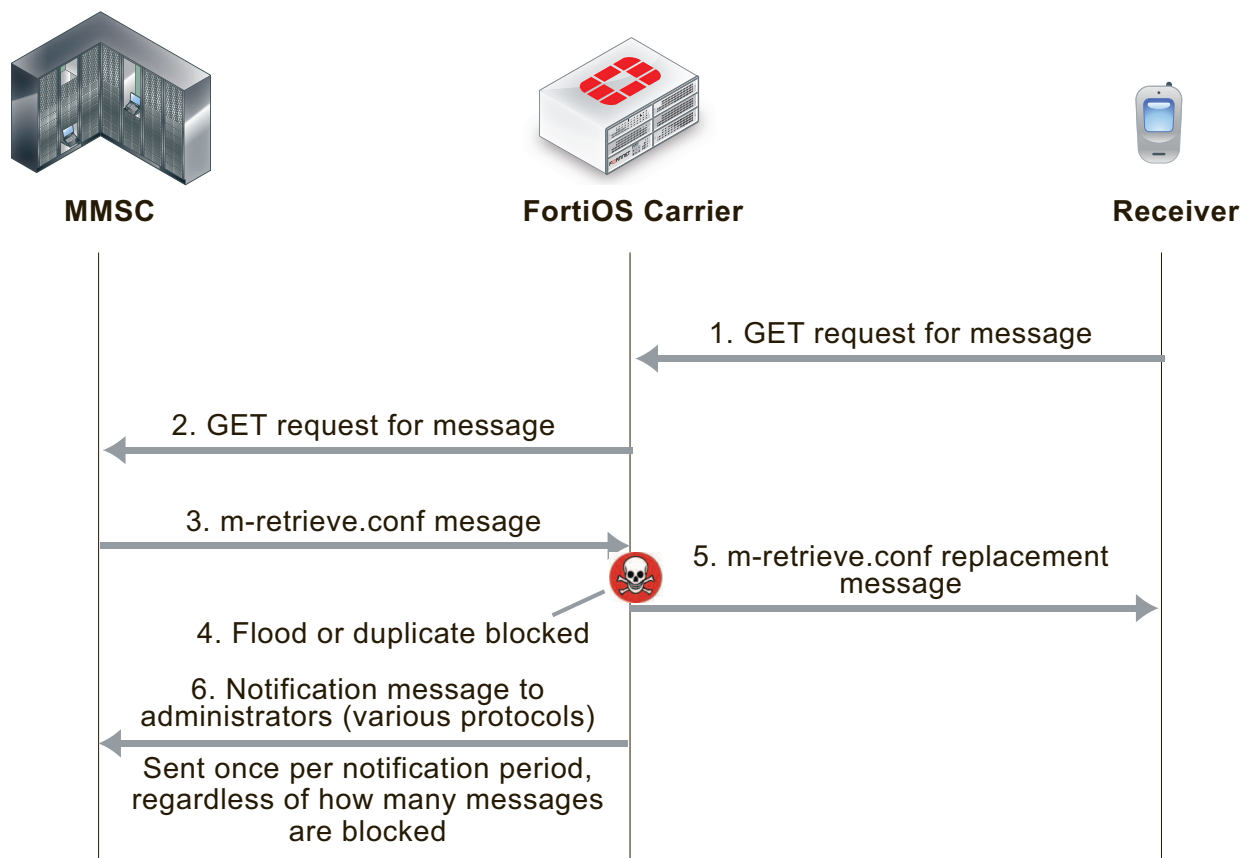

For message floods and duplicate messages, the sender does not receive notifications about floods or duplicate messages, as if the sender is an attacker they can gain useful information about flood and duplicate thresholds. Plus, duplicate messages and message floods are usually a result of a large amount of messaging activity and filtering of these messages is designed to reduce the amount of unwanted messaging traffic. Adding to the traffic by sending notifications to senders and receivers could result in an increase in message traffic.

You can create up to three thresholds for detecting duplicate messages and message floods. For each threshold you can configure the FortiOS Carrier unit to respond by logging the activity, archiving or quarantining the messages, notifying administrators of the activity, and by blocking the messages. In many cases you may only want to configure blocking for higher activity thresholds, and to just monitor and send administrator notifications at lower activity thresholds.

When a block threshold is reached for MM1 messages, FortiOS Carrier sends `m-send.conf` or `m-retrieve.conf` messages to the originator of the activity. These messages are sent to end the MM1 sessions, otherwise the originator would continue to re-send the blocked message. When a block threshold is reached for MM4, FortiOS Carrier sends a `MM4-forward.res` message to close the MM4 session. An MM4 message is sent only if initiated by the originating `MM4-forward.req` message.

### MM1 message flood and duplicate message blocking of sent messages

**MM1 message flood and duplicate message blocking of received messages**

**MM4 message flood and duplicate message blocking****MMS protection profiles**

An MMS protection profile is a group of settings that you can apply to an MMS session matched by a security policy.

MMS protection profiles are easy to configure and can be used by more than one security policy. You can configure a single MMS protection profile for the different traffic types handled by a set of security policies that require identical protection levels and types. This eliminates the need to repeatedly configure those same MMS protection profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need only moderate protection. You would configure two separate MMS protection profiles to provide the different levels of protection: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS Protection Profile, you need to add it to a security policy to apply the profile to MMS traffic.

## Bypassing MMS protection profile filtering based on carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from MMS protection profile filtering. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns. If you add a carrier endpoint pattern to a filter list and set the action to exempt from all scanning, all messages from matching carrier endpoints bypass MMS protection profile filtering. See Bypassing message flood protection based on user's carrier endpoints.

## Applying MMS protection profiles to MMS traffic

To apply an MMS protection profile you must first create the MMS protection profile and then add the MMS protection profile to a security policy by enabling the Carrier security profile. The MMS protection profile then applies itself to the traffic accepted by that security policy.

MMS protection profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS protection profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS protection profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS protection profile.

### To add an MMS protection profile to a security policy

1. Go to **Security Profiles > MMS Profile**.
2. Select **Create New** to add an MMS protection profile.
3. Configure as needed, and save.
4. Go to **Policy & Objects > IPv4 Policy**.
5. Select **Create New** to add a security policy, or select an existing policy and **Edit** to add the MMS profile.
6. Configure the security policy as required.
7. Enable **MMS Profile**, and select the MMS profile to add to the security policy.
8. Select **OK**.

## MMS Configuration

### MMS profiles

Since MMS profiles can be used by more than one security policy, you can configure one profile for the traffic types handled by a set of security policies requiring identical protection levels and types, rather than repeatedly configuring those same profile settings for each individual security policy.

If the security policy requires authentication, do not select the MMS profile in the security policy. This type of profile is specific to the authenticating user group. For details on configuring the profile associated with the user group, see User Groups in the Authentication guide.

---

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need moderate protection. To provide the different levels of protection, you might configure two separate protection profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS profile, you can then apply the profile to MMS traffic by applying it to a security policy.

MMS profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS profile.

The MMS Profile page contains options for each of the following:

- MMS scanning
- MMS Bulk Email Filtering Detection
- MMS Address Translation
- MMS Notifications
- DLP Archive
- Logging

### MMS profile configuration settings

The following are MMS profile configuration settings in **Security Profiles > MMS Profile**.

<b>MMS Profile page</b>	
Lists each individual MMS profile that you created. On this page, you can edit, delete or create an MMS profile.	
<b>Create New</b>	Creates a new MMS profile. When you select <b>Create New</b> , you are automatically redirected to the New MMS Profile page.
<b>Edit</b>	Modifies settings within an MMS profile. When you select <b>Edit</b> , you are automatically redirected to the Edit MMS Profile.
<b>Delete</b>	Removes an MMS profile from the list on the MMS Profile page.
	To remove multiple MMS profiles from within the list, on the MMS Profile page, in each of the rows of the profiles you want removed, select the check box and then select <b>Delete</b> .
	To remove all MMS profiles from the list, on the MMS Profile page, select the check box in the check box column, and then select <b>Delete</b> .
<b>Name</b>	The name of the MMS profile.

Displays the number of times the object is referenced to other objects. For example, av\_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus**), 1 appears in **Ref.** .

To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object.

To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window:

#### Ref.

**View the list page for these objects** – automatically redirects you to the list page where the object is referenced at.

**Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av\_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page.

**View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av\_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

### New MMS Profile page

Provides settings for configuring an MMS profile. This page also provides settings for configuring DLP archives and logging.

<b>Profile Name</b>	Enter a name for the profile.
<b>Comments</b>	Enter a description about the profile. This is optional.
<b>MMS Scanning</b>	Configure MMS Scanning options.
<b>MMS Bulk Email Filtering Detection</b>	Configure MMS Bulk Email options.
<b>MMS Address Translation</b>	Configure MMS Address Translation options.
<b>MMS Notifications</b>	Configure MMS Notification options.
<b>DLP Archive</b>	Configure DLP archive option.
<b>Logging</b>	Configure logging options.

### MMS scanning options

You can configure MMS scanning protection profile options to apply virus scanning, file filtering, content filtering, carrier endpoint blocking, and other scanning to MMS messages transmitted using the MM1, MM3, MM4 and

MM7 protocols.

The following are the MMS Scanning options that are available within an MMS profile. You can create an MMS profile in **Security Profiles > MMS Profile** or edit an existing one. You must expand MMS Scanning to access the following options.

#### MMS Scanning section of the New MMS Profile page

<b>Monitor Only</b>	<p>Select to cause the unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Select this option to be able to report on viruses and other problems in MMS traffic without affecting users.</p> <p><b>Tip:</b> Select <b>Remove Blocked</b> if you want the unit to actually remove content intercepted by MMS scanning options.</p>
<b>Virus Scan</b>	<p>Select to scan attachments in MMS traffic for viruses.</p> <p>Since MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configuration also applies to MM1 and MM7 scanning.</p> <p>MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configuration also applies to MM3 and MM4 scanning.</p>
<b>Scan MM1 message retrieval</b>	<p>Select to scan message retrievals that use MM1. If you enable <b>Virus Scan</b> for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.</p>
<b>Remove Blocked</b>	<p>Select to remove blocked content from each protocol and replace it with the replacement message.</p> <p>Select <b>Constant</b> if the unit is to preserve the length of the message when removing blocked content, as may occur when billing is affected by the length of the message.</p> <p><b>Tip:</b> If you only want to monitor blocked content, select <b>Monitor Only</b>.</p>
<b>Content Filter</b>	<p>Select to filter messages based on matching the content of the message with the words or patterns in the selected web content filter list.</p> <p>For information about adding a web content filter list, see the <a href="#">FortiGate CLI Reference</a>.</p>
<b>Carrier Endpoint Block</b>	<p>Select to add <b>Carrier Endpoint Filtering</b> in this MMS profile. Select the carrier endpoint filter list to apply it to the profile.</p>

### MMS Scanning section of the New MMS Profile page

<b>MMS Content Checksum</b>	Select to add MMS Content Checksum in this MMS profile. Select the MMS content checksum list to apply it to the profile.
<b>Pass Fragmented Messages</b>	Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 message are blocked.
<b>Comfort Clients</b>	<p>Select client comforting for MM1 and MM7 sessions.</p> <p>Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.</p>
<b>Comfort Servers</b>	<p>Select server comforting for each protocol.</p> <p>Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for the unit to buffer and scan large POST requests from slow clients.</p>
<b>Interval (1-900 seconds)</b>	Enter the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.
<b>Amount (1-10240 bytes)</b>	The number of bytes sent by client or server comforting at each interval.
<b>Oversized MMS Message</b>	<p>Select <b>Block</b> or <b>Pass</b> for files and email messages exceeding configured thresholds for each protocol.</p> <p>The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.</p>
<b>Threshold (1KB - 800 MB)</b>	Enter the oversized file threshold and select KB or MB. If a file is larger than the threshold the file is passed or blocked depending on the <b>Oversized MMS Message</b> setting. The web-based manager displays the allowed threshold range. The threshold maximum is 10% of the unit's RAM.

### MMS Bulk Anti-Spam Detection options

You can use the MMS bulk email filtering options to detect and filter MM1 and MM4 message floods and duplicate messages. You can configure three thresholds that define a flood of message activity and three thresholds that define excessive duplicate messages. The configuration of each threshold includes the response actions for the threshold.

The configurable thresholds for each of the flood and duplicate sensors and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

You can also add MSISDN to the bulk email filtering configuration and select a subset of the bulk email filtering options to applied to these individual MSISDNs.

You must first select MM1 and/or MM4 to detect excessive message duplicates. If excessive message duplicates are detected, the unit will perform the **Duplicate Message Action** for the specified duration.

You can configure three duplicate message thresholds and enable them with separate values and actions. They are labeled Duplicate Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Duplicate Threshold 1 and Duplicate Threshold 2, but you cannot disable Duplicate Threshold 1 and enable Duplicate Threshold 2.

When traffic accepted by a security policy that contains an MMS profile with duplicate message configured receives MM1 or MM4 duplicate messages that match a threshold configured in the MMS protection profile, the unit performs the duplicate message action configured for the matching threshold.

You can configure three message flood thresholds and enable them with separate values and actions. They are labeled Flood Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

When traffic accepted by a security policy that contains an MMS protection profile with message flooding configured experiences MM1 or MM4 message flooding that matches a threshold configured in the MMS profile, the unit performs the message flood action configured for the matching threshold.

### MMS Bulk Anti-Spam Detection

This section of the New MMS Profile page contains numerous sections where you can configure specific settings for flood threshold, duplicate threshold and recipient MSISDNs.

#### Message Flood

The message flood settings for each flood threshold. Expand each to configure settings for a threshold.

<b>Flood Threshold 1</b>	Expand to reveal the flood threshold settings for Flood Threshold 1. The settings for Flood Threshold 1 are the same for Flood Threshold 2 and 3.
<b>Enable</b>	Select to apply Flood Threshold 1 to the MSISDN exception.
<b>Message Flood Window</b>	Enter the period of time during which a message flood will be detected if the <b>Message Flood Limit</b> is exceeded. The message flood window can be 1 to 2880 minutes (48 hours).
<b>Message Flood Limit</b>	Enter the number of messages which signifies a message flood if exceeded within the <b>Message Flood Window</b> .
<b>Message Flood Block Time</b>	Enter the amount of time during which the unit performs the <b>Message Flood Action</b> after a message flood is detected.

<b>Message Flood Action</b>	Select one or more actions that the unit is to perform when a message flood is detected.
<b>Flood Threshold 2</b>	Expand to configure settings for Flood Threshold 2 or 3 respectively.
<b>Flood Threshold 3</b>	
<b>Duplicate Message</b>	The duplicate message threshold settings. Expand each to configure settings for a threshold.
<b>MM1 Retrieve Duplicate Enable</b>	Select to scan MM1 <code>mm1-retr</code> messages for duplicates. By default, <code>mm1-retr</code> messages are not scanned for duplicates as they may often be the same without necessarily being bulk or spam.
<b>Enable</b>	Select to enable the selected duplicate message threshold and to make the rest of the options available for configuration.
<b>Duplicate Message Window</b>	Enter the period of time during which excessive message duplicates will be detected if the Duplicate message Limit it exceeded. The duplicate message window can be 1 to 2880 minutes (48 hours).
<b>Duplicate Message Limit</b>	Enter the number of messages which signifies excessive message duplicates if exceeded within the Duplicate Message Window.
<b>Duplicate Message Block Time</b>	Enter the amount of time during which the unit will perform the Duplicate Message Action after a message flood is detected.
<b>Duplicate Message Action</b>	Select one or more actions that the unit is to perform when excessive message duplication is detected.
<b>Duplicate Threshold 2</b>	Expand to configure settings for Duplicate Threshold 2 or 3 respectively.
<b>Duplicate Threshold 3</b>	
<b>Recipient MSISDN</b>	The recipient Mobile Subscriber Integrated Services Digital Network Number (MSISDN) settings for each recipient MSISDN. When you select <b>Create New</b> , you are automatically redirected to the New MSISDN page.  You need to save the profile before you can add MSISDNs.
<b>Recipient MSISDN</b>	The recipient MSISDN.
<b>Flood Threshold 1</b>	Check to enable Flood Threshold 1 settings for this MSISDN.
<b>Flood Threshold 2</b>	Check to enable Flood Threshold 2 settings for this MSISDN.
<b>Flood Threshold 3</b>	Check to enable Flood Threshold 3 settings for this MSISDN..

<b>Duplicate Threshold 1</b>	Check to enable Duplicate Threshold 1 settings for this MSISDN.
<b>Duplicate Threshold 2</b>	Check to enable Duplicate Threshold 2 settings for this MSISDN..
<b>Duplicate Threshold 3</b>	Check to enable Duplicate Threshold 3 settings for this MSISDN..
<b>Edit</b>	Modifies the settings of a Recipient MSISDN in the Recipient MSISDN list. When you select <b>Edit</b> , you are automatically redirected to the New MSISDN page.
<b>Delete</b>	Removes a Recipient MSISDN in the Recipient MSISDN list within the Recipient MSISDN section of the page.
<b>New MSISDN page</b>	
<b>Create New</b>	Creates a new Recipient MSISDN. When you select <b>Create New</b> , you are automatically redirected to the New MSISDN page.
<b>Recipient MSISDN</b>	Enter a name for the recipient MSISDN.
<b>Flood Threshold 1</b>	Select to apply Flood Threshold 1 to the MSISDN exception.
<b>Flood Threshold 2</b>	Select to apply Flood Threshold 2 to the MSISDN exception.
<b>Flood Threshold 3</b>	Select to apply Flood Threshold 3 to the MSISDN exception.
<b>Duplicate Threshold 1</b>	Select to apply Duplicate Threshold 1 to the MSISDN exception.
<b>Duplicate Threshold 2</b>	Select to apply Duplicate Threshold 2 to the MSISDN exception.
<b>Duplicate Threshold 3</b>	Select to apply Duplicate Threshold 3 to the MSISDN exception.

## MMS Address Translation options

The sender's carrier endpoint is used to provide logging and reporting details to the mobile operator and to identify the sender of infected content.

When MMS messages are transmitted, the **From** field may or may not contain the sender's address. When the address is not included, the sender information will not be present in the logs and the unit will not be able to notify the user if the message is blocked unless the sender's address is made available elsewhere in the request.

The unit can extract the sender's address from an extended HTTP header field in the HTTP request. This field must be added to the HTTP request before it is received by the unit. If this field is present, it will be used instead of the sender's address in the MMS message for logging and notification. If this header field is present when a message is retrieved, it will be used instead of the **To** address in the message. If this header field is not present the content of the **To** header field is used instead.

Alternatively, the unit can extract the sender's address from a cookie.

You can configure MMS address translation to extract the sender's carrier endpoint so that it can be added to log and notification messages. You can configure MMS address translation settings to extract carrier endpoints from HTTP header fields or from cookies. You can also configure MMS address translation to add an endpoint prefix to

the extracted carrier endpoints. For more information, see Dynamic Profiles and Endpoints in the Authentication guide.

### MMS Address Translation

#### Sender Address Source

Select to extract the sender's address from the **HTTP Header Field** or a **Cookie**. You must also specify the identifier that contains the carrier endpoint.

Enter the sender address identifier that includes the carrier endpoint. The default identifier is `x-up-calling-line-id`.

If the **Sender Address Source** is **HTTP Header Field**, the address and its identifier in the HTTP request header takes the format:

```
<Sender Address Identifier>: <MSISDN_value>
```

Where the `<MSISDN_value>` is the carrier endpoint. For example, the HTTP header might contain:

```
x-up-calling-line-id: 6044301297
```

where `x-up-calling-line-id` would be the Sender Address Identifier.

#### Sender Address Identifier

If the **Sender Address Source** is **Cookie**, the address and its identifier in the HTTP request header's `Cookie` field takes the format of attribute-value pairs:

```
Cookie: id=<cookie-id>;
```

```
<Sender Address Identifier>=<MSISDN Value>
```

For example, the HTTP request headers might contain:

```
Cookie: id=0123jff!a;x-up-calling-line-id=6044301297
```

where `x-up-calling-line-id` would be the **Sender Address Identifier**.

#### Convert Sender Address From / To HEX

Select to convert the sender address from ASCII to hexadecimal or from hexadecimal to ASCII. This is required by some applications.

#### Add Carrier Endpoint Prefix for Logging / Notification

Select the following to enable adding endpoint prefixes for logging and notification.

#### Enable

Select to enable adding the country code to the extracted carrier endpoint, such as the MSISDN, for logging and notification purposes. You can limit the number length for the test numbers used for internal monitoring without a country code.

### MMS Address Translation

<b>Prefix</b>	Enter a carrier endpoint prefix to be added to all carrier endpoints. Use the prefix to add extra information to the carrier endpoint in the log entry.
<b>Minimum Length</b>	Enter the minimum length of the country code information being added. If this and Maximum Length are set to zero (0), length is not limited.
<b>Maximum Length</b>	Enter the maximum length of the country code information being added. If this and Minimum Length are set to zero (0), length is not limited.

### MMS Notifications

MMS notifications are messages that a unit sends when an MMS profile matches content in an MM1, MM3, MM4 or MM7 session. For example, the MMS profile detects a virus or uses content blocking to block a web page, text message or email. You can send notifications to the sender of the message using same protocol and the addressing headers in the original message. You can also configure MMS notifications to send notification messages to another destination (such as a system administrator) using the MM1, MM3, MM4 or MM7 protocol.

You need to enable one or more **Notification Types** or you can add an **Antivirus Notification List** to enable sending notifications,.

You can also use MMS notifications options to configure how often notifications are sent. The unit sends notification messages immediately for the first event, then at a configurable interval if events continue to occur. If the interval does not coincide with the window of time during which notices may be sent, the unit waits to send the notice in the next available window. Subsequent notices contain a count of the number of events that have occurred since the previous notification.

There are separate notifications for each notification type, including virus events. Virus event notifications include the virus name. Up to three viruses are tracked for each user at a time. If a fourth virus is found, one of the existing tracked viruses is removed from the list.

The notifications are MM1 `m-send-req` messages sent from the unit directly to the MMSC for delivery to the client. The host name of the MMSC, the URL to which `m-send-req` messages are sent, and the port must be specified.

### MMS Notification

<b>Antivirus Notification List</b>	<p>Optionally select an antivirus notification list to select a list of virus names to send notifications for. The unit sends a notification message whenever a virus name or prefix in the antivirus notification list matches the name of a virus detected in a session scanned by the MMS protection profile. Select <b>Disabled</b> if you do not want to use a notification list.</p> <p>Instead of selecting a notification list you can configure the <b>Virus ScanNotification Type</b> to send notifications for all viruses.</p>
------------------------------------	--

## MMS Notification

<b>Message Protocol</b>	<p>In each column, select the protocol used to send notification messages. You can use a different protocol to send the notification message than the protocol on which the violation was sent. The MMS Notifications options change depending on the message protocol that you select.</p> <p>If you select a different message protocol, you must also enter the User Domain. If selecting MM7 you must also enter the Message Type.</p>
<b>Message Type</b>	Select the MM7 message type to use if sending notifications using MM7. Options include deliver.REQ and submit.REQ
<b>Detect Server Details</b>	<p>Select to use the information in the headers of the original message to set the address of the notification message. If you do not select this option, you can enter the required addressing information manually.</p> <p>You cannot select <b>Detect Server Details</b> if you are sending notification messages using a different message protocol.</p> <p>If you select <b>Detect Server Details</b>, you cannot change the <b>Port</b> where the notification is being sent.</p>
<b>Hostname</b>	Enter the FQDN or the IP address of the server where the notifications will be sent.
<b>URL</b>	<p>Enter the URL of the server. For example if the notification is going to www.example.com/home/alerts , the URL is /home/alerts.</p> <p>This option is available only when <b>Message Protocol</b> is <b>mm1</b> or <b>mm7</b>.</p>
<b>Port</b>	<p>Enter the port number of the server.</p> <p>You cannot change the <b>Port</b> if <b>Detect Server Details</b> is enabled.</p>
<b>Username</b>	<p>Enter the user name required for sending messages using this server (optional).</p> <p>This option is available only when <b>Message Protocol</b> is <b>mm7</b>.</p>
<b>Password</b>	<p>Enter the password required for sending messages using this server (optional).</p> <p>This option is available only when <b>Message Protocol</b> is <b>mm7</b>.</p>

## MMS Notification

### VASP ID

Enter the value-added-service-provider (VASP) ID to be used when sending a notification message. If a VAS is not offered by the mobile provider, it is offered by a third party or a VAS provider or content provider (CP).

This option is available only when **Message Protocol** is **mm7**.

### VAS ID

Enter the value-added-service (VAS) ID to be used when sending a notification message. A VAS is generally any service beyond voice calls and fax.

This option is available only when **Message Protocol** is **mm7**.

### All Notification Types

In each column, select notification for all MMS event types for that MMS protocol, then enter the amount of time and select the time unit for notice intervals.

Alternatively, expand **All Notification Types**, and then select notification for individual MMS event types for each MMS protocol. Then enter the amount of time and select the time unit for notice intervals.

Not all event types are available for all MMS protocols.

### Content Filter

In each column, select to notify when messages are blocked by the content filter, then enter the amount of time and select the time unit for notice intervals.

### File Block

In each column, select to notify when messages are blocked by file block, then enter the amount of time and select the time unit for notice intervals.

### Carrier Endpoint Block

In each column, select to notify when messages are blocked, then enter the amount of time and select the time unit for notice intervals.

### Flood

In each column, select to notify when message flood events occur, then enter the amount of time and select the time unit for notice intervals.

### Duplicate

In each column, select to notify when duplicate message events occur, then enter the amount of time and select the time unit for notice intervals.

### MMS Content Checksum

In each column, select to notify when the content within an MMS message is scanned and banned because of the checksum value that was matched.

### Virus Scan

In each column, select to notify when the content within an MMS message is scanned for viruses.

## MMS Notification

### Notifications Per Second Limit

For each MMS protocol, enter the number of notifications to send per second. If you enter zero ( 0 ), the notification rate is not limited.

### Day of Week

For each MMS protocol, select the days of the week the unit is allowed to send notifications.

### Window Start Time

For each MMS protocol, select the time of day to begin the message alert window. By default, the message window starts at 00:00. You can change this if you want to start the message window later in the day. When configured, notification outside this window will not be sent.

### Window Duration

For each MMS protocol, select the time of day at which to end the message alert window. By default, the message window ends at 00:24. You can change this if you want to end the message window earlier in the day.

When configured, notification outside this window will not be sent

## DLP Archive options

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. In addition to the MMS profile's DLP archive options, you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select **DLP archiving** for carrier endpoint patterns in a **Carrier Endpoint List** and select the **Carrier Endpoint Block** option in the **MMS Scanning** section of an MMS Profile

The unit only allows one sixteenth of its memory for transferring content archive files. For example, for units with 128 MB RAM, only 8 MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

## DLP Archive

### Display DLP meta-information on the system dashboard

Select each required protocol to display the content archive summary in the Log and Archive Statistics dashboard widget on the System Dashboard.

## DLP Archive

### Archive to FortiAnalyzer/FortiGuard

Select the type of archiving that you want for the protocol (MM1, MM3, MM4, and MM7). You can choose from Full, Summary or None.

**None** — Do not send content archives.

**Summary** — Send content archive metadata only. Includes information such as date and time, source and destination, request and response size, and scan result.

**Full** — Send content archive both metadata and copies of files or messages.

In some cases, FortiOS Carrier may not archive content, or may make only a partial content archive, regardless of your selected option. This behavior varies by prerequisites for each protocol.

This option is available only if a FortiAnalyzer unit or FortiGuard Analysis and Management Service is configured.

## Logging

You can enable logging in an MMS profile to write event log messages when the MMS profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS profile logging options to write an event log message every time a virus is detected.

You must first configure how the unit stores log messages so that you can then record these logs messages. For more information, see the FortiOS Handbook Logging and Reporting guide.

## Logging

### MMS-Antivirus

If antivirus settings are enabled for this MMS profile, select the following options to record **Antivirus Log** messages.

#### Viruses

Record a log message when this MMS profile detects a virus.

#### Blocked Files

Record a log message when antivirus file filtering enabled in this MMS profile blocks a file.

#### Oversized Files/Emails

Record a log message when this MMS profile encounters an oversized file or email message. Oversized files and email messages cannot be scanned for viruses.

### MMS Scanning

If MMS scanning settings are enabled for this MMS profile, select the following options to record **Email Filter Log** messages.

#### Notification Messages

Select to log the number of MMS notification messages sent.

Logging	
<b>Bulk Messages</b>	Select to log MMS Bulk AntiSpam events. You must also select which protocols to write log messages for in the MMS bulk email filtering part of the MMS profile.
<b>Carrier Endpoint Filter Block</b>	Select to log MMS carrier endpoint filter events, such as MSISDN filtering.
<b>MMS Content Checksum</b>	Select to log MMS content checksum activity.
<b>Content Block</b>	Select to log content blocking events.

## MMS Content Checksum

The MMS Content Checksum menu allows you to configure content checksum lists.

Configure MMS content checksum lists in **Security Profiles > MMS Content Checksum** using the following table.

MMS Content Checksum	
Lists each individual content checksum list that you created. On this page, you can edit, delete or create a content checksum list.	
<b>Create New</b>	Creates a new MMS content checksum list. When you select <b>Create New</b> , you are automatically redirected to the New List. This page provides a name field and comment field. You must enter a name to go to MMS Content Checksum Settings page.
<b>Edit</b>	Modifies settings to a MMS content checksum. When you select <b>Edit</b> , you are automatically redirected to the MMS Content Checksum Settings page.
<b>Delete</b>	Removes an MMS content checksum from the page.
	To remove multiple content checksum lists from within the list, on the MMS Content Checksum page, in each of the rows of the content checksum lists you want removed, select the check box and then select <b>Delete</b> .
	To remove all content checksum lists from list, on the MMS Content Checksum page, select the check box in the check box column and then select <b>Delete</b> .
<b>Name</b>	The name of the MMS content checksum list that you created.
<b># Entries</b>	The number of checksums that are included in the content checksum list.

<b>MMS Profiles</b>	The MMS profile or profiles that have the MMS content checksum list applied. For example if two different MMS profiles use this content checksum list, they will both be listed here.
<b>Comments</b>	A description given to the MMS content checksum.
<b>Ref.</b>	<p>Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (<b>Security Profiles &gt; AntiVirus &gt; Profiles</b>), 1 appears in <b>Ref.</b> .</p> <p>To view the location of the referenced object, select the number in <b>Ref.</b>, and the Object Usage window appears displaying the various locations of the referenced object.</p> <p>To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window:</p> <ul style="list-style-type: none"> <li>• <b>View the list page for these objects</b> – automatically redirects you to the list page where the object is referenced at.</li> <li>• <b>Edit this object</b> – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page.</li> <li>• <b>View the details for this object</b> – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.</li> </ul>

## Notification List

The Notification List menu allows you to configure a list of viruses. This virus list provides a list for scanning viruses in MMS messages. You can use one virus list in multiple MMS profiles, and configure multiple virus lists.

### Notification list configuration settings

The following are notification list configuration settings in **Security Profiles > Notification List**.

<b>Notification List</b>	Lists all the notification lists that you created. On this page you can edit, delete or create a new notification list.
<b>Create New</b>	Creates a new notification list. When you select <b>Create New</b> , you are automatically redirected to the New List page. You must enter a name to go to the Notification List Settings page.

<b>Edit</b>	Modifies settings within the notification list. When you select <b>Edit</b> , you are automatically redirected to the Notification List Settings page.
<b>Delete</b>	<p>Removes a notification list from the list on the Notification List page.</p> <p>To remove multiple notification lists from within the list, on the Notification List page, in each of the rows of the notification lists you want removed, select the check box and then select <b>Delete</b>.</p> <p>To remove all notification lists from the list, on the Notification List page, select the check box in the check box column and then select <b>Delete</b>.</p>
<b>Name</b>	The name of the MMS content checksum list that you created.
<b># Entries</b>	The number of checksums that are included in that content checksum list.
<b>MMS Profiles</b>	The MMS profile or profiles that are associated with
<b>Comments</b>	A description given to the MMS notification list.
<b>Ref.</b>	<p>Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (<b>Security Profiles &gt; Antivirus &gt; Profiles</b>), 1 appears in <b>Ref.</b> .</p> <p>To view the location of the referenced object, select the number in <b>Ref.</b>, and the Object Usage window appears displaying the various locations of the referenced object.</p> <p>To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window:</p> <ul style="list-style-type: none"> <li>• <b>View the list page for these objects</b> – automatically redirects you to the list page where the object is referenced at.</li> <li>• <b>Edit this object</b> – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page.</li> <li>• <b>View the details for this object</b> – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.</li> </ul>
<b>Notification List Settings</b>	
Provides settings for configuring a notification list, which is a list of viruses and is used for scanning viruses in MMS messages. This list is called the Antivirus Notification List in an MMS profile.	

<b>Name</b>	If editing the name of a notification list, enter the new name in this field. You must select <b>OK</b> to save the change.
<b>Comments</b>	If you want to enter a comment, enter the comment in the field. You must select <b>OK</b> to save the change.
<b>Create New</b>	Creates a notification entry in the list. When you select <b>Create New</b> , you are automatically redirected to the New Entry page.
<b>Edit</b>	Modifies settings within a notification list. When you select <b>Edit</b> , you are automatically redirected to the Edit Entry page.
<b>Delete</b>	Removes a notification entry from the list on the page.  To remove multiple notification entries from within the list, on the Notification List Settings page, in each of the rows of the entries you want removed, select the check box and then select <b>Delete</b> .  To remove all notification entries from the list, on the Notification List Settings page, select the check box in the check box column and then select <b>Delete</b> .
<b>Enable</b>	Enables a notification entry that is disabled.
<b>Disable</b>	Disables a notification entry so that it is not active and available for use, but it is not deleted.
<b>Remove All Entries</b>	Removes all notification entries that are listed on the Notification List Settings page.
<b>Enable</b>	Displays whether or not the checksum is enabled.
<b>Virus Name/Profile</b>	The name of the virus that was added to the list.
<b>Entry Type</b>	The type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
<b>New Entry page</b>	
<b>Virus Name/Profile</b>	Enter the virus name.
<b>Entry Type</b>	Select the type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
<b>Enable</b>	Select to enable the virus in the list.

## Message Flood

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse. A

message flood occurs when a single subscriber sends a volume of messages that exceed the flood threshold that you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected. For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all outgoing messages blocked for 30 minutes.

Action	Description
<b>Log</b>	Add a log entry indicating that a message flood has occurred. You must also enable logging by going to <b>Security Profiles &gt; MMS Profile</b> , <applicable profile> > <b>Logging &gt; MMS Scanning &gt; Bulk Messages</b> , and toggling on the checkbox.
<b>DLP Archive</b>	Save the first message to exceed the flood threshold, or all the messages that exceed the flood threshold, in the DLP archive. DLP archiving flood messages may not always produce useful results. Since different messages can be causing the flood, reviewing the archived messages may not be a good indication of what is causing the problem since the messages could be completely random.
<b>All messages</b>	All the messages that exceed the flood threshold will be saved in the DLP archive.
<b>First message only</b>	Save only the first message to exceed the flood threshold in the DLP archive. Other messages in the flood are not saved. For message floods this may not produce much useful information since a legitimate message could trigger the flood threshold.
<b>Intercept</b>	Messages that exceed the flood threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message will also be quarantined for later examination. If the quarantine of intercepted messages is disabled, the <b>Intercept</b> action has no effect.
<b>Block</b>	Messages that exceed the flood threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each message will be quarantined for later examination.
<b>Alert Notification</b>	<p>If the flood threshold is exceeded, the Carrier-enabled FortiGate unit will send an MMS flood notification message.</p> <p>In the web-based manager when <b>Alert Notification</b> is selected it displays the fields to configure the notification.</p>

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many messages from the same subscriber to your MMSC.

### Message flood configuration settings

The following are message flood configuration settings in **Security Profiles > Message Flood**.

**Message Flood**

Lists the large amount of messages that are being sent to you from outside sources.

<b>Delete</b>	Removes messages from the list.
	To remove multiple messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select <b>Delete</b> .
	To remove all messages from the list, on the Message Flood page, select the check box in the check box column and then select <b>Delete</b> .
<b>Remove All Entries</b>	Removes all messages from the list.
<b>Protocol</b>	Sorts/filters by the protocol used.
<b>MMS Profile</b>	Sorts/filters by the MMS profile that is used.
<b>Sender</b>	Sorts/filters by the sender's email address.
<b>Level</b>	Sorts/filters by the level of severity of the message.
<b>Count</b>	The count column can be up or down and these settings can be turned off by selecting beside the column's name.
<b>Window Size (minutes)</b>	The time in minutes.
<b>Timer (minutes:seconds)</b>	The time in seconds and in minutes. The timer column can be up or down and these settings turned off by selecting beside the column's name.
<b>Page Controls</b>	Use to navigate through the list.

## Duplicate Message

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC.

The unit keeps track of the sent messages. If the same message appears more often than the threshold value that you have configured, action is taken. Possible actions are logging the duplicate messages, blocking or intercepting them, archiving, and sending an alert to inform an administrator that duplicate messages are occurring.

### Duplicate message configuration settings

View duplicate messages in **Security Profiles > Duplicate Message**.

<b>Duplicate Message</b>	
Lists duplicates of messages that were sent to you.	
<b>Delete</b>	Removes a message from the list.
	To remove multiple duplicate messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select <b>Delete</b> .
	To remove all duplicate messages from the list, on the Message Flood page, select the check box in the check box column and then select <b>Delete</b> .
<b>Page Controls</b>	Use to navigate through the list.
<b>Remove All Entries</b>	Removes all duplicate messages from the list.
<b>Protocol</b>	Sorts/filters by the protocol used.
<b>MMS Profile</b>	Sorts/filters by the MMS profile that logs the detection.
<b>Checksum</b>	Sorts/filters by the checksum of the MMS message.
<b>Level</b>	Sorts/filters by the level of severity of the message.
<b>Count</b>	Displays the number of messages in the last window of time.
<b>Window Size (minutes)</b>	The period of time during which a message flood will be detected if the Message Flood Limit is exceeded.
<b>Timer (minutes:seconds)</b>	Either the time left in the window if the message is unflagged, or the time until the message will be unflagged if it is already flagged.

## Carrier Endpoint Filter Lists

A carrier endpoint filter list contains carrier endpoint patterns. A pattern can match one carrier endpoint or can use wildcards or regular expressions to match multiple carrier endpoints. For each pattern, you select the action that the unit takes on a message when the pattern matches a carrier endpoint in the message. Actions include blocking the message, exempting the message from MMS scanning, and exempting the message from all scanning. You can also configure the pattern to intercept the message and content archive the message to a FortiAnalyzer unit.

### Carrier endpoint filter lists configuration settings

The following are Carrier endpoint filter list configuration settings in **Security Profiles > Carrier Endpoint Filter Lists**.

### Carrier Endpoint Filter Lists

Lists all the endpoint filters that you created. On this page, you can edit, delete or create a new endpoint filter list.

<b>Create New</b>	Creates a new endpoint filter list. When you select <b>Create New</b> , you are automatically redirected to the New List page. You must enter a name to go to the Carrier Endpoint Filter Lists Settings page.
<b>Edit</b>	Modifies settings within an endpoint filter list in the list.
<b>Delete</b>	<p>Removes an endpoint filter in the list.</p> <p>To remove multiple endpoint filter lists from within the list, on the Carrier Endpoint Filter List page, in each of the rows of the endpoint filter lists you want removed, select the check box and then select <b>Delete</b>.</p> <p>To remove all endpoint filter lists from the list, on the Carrier Endpoint Filter List page, select the check box in the check box column and then select <b>Delete</b>.</p>
<b>Name</b>	The name of the endpoint filter.
<b># Entries</b>	The number of carrier endpoint patterns in each carrier endpoint filter list.
<b>MMS Profiles</b>	The MMS profile that the carrier endpoint filter list is added to.
<b>Comments</b>	A description about the endpoint filter.

<b>Ref.</b>	<p>Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (<b>Security Profiles &gt; Antivirus &gt; Profiles</b>), 1 appears in <b>Ref.</b> .</p> <p>To view the location of the referenced object, select the number in <b>Ref.</b>, and the Object Usage window appears displaying the various locations of the referenced object.</p> <p>To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window:</p> <ul style="list-style-type: none"> <li>• <b>View the list page for these objects</b> – automatically redirects you to the list page where the object is referenced at.</li> <li>• <b>Edit this object</b> – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page.</li> <li>• <b>View the details for this object</b> – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.</li> </ul>
-------------	---

### Carrier Endpoint Filter Lists Settings

Provides settings for configuring an endpoint filter.

<b>Name</b>	The name you entered on the New List page, after selecting <b>Create New</b> on the Carrier Endpoint Filter page.
<b>Comments</b>	A description about the endpoint filter. You can add one here if you did not enter one on the New List page.
<b>Create New</b>	Creates a new endpoint filter list. When you select <b>Create New</b> , you are automatically redirected to the New Entry page.
<b>Edit</b>	Select to modify the settings of a pattern in the list.
<b>Delete</b>	Select to remove a pattern in the list.
<b>Enable</b>	Enables a disabled pattern in the list.
<b>Disable</b>	Disables a pattern in the list.
<b>Remove All Entries</b>	Removes all patterns in the list on the Carrier Endpoint Filter Lists Settings page.
<b>Enable</b>	Indicates whether or not the pattern is enabled.

<b>Pattern</b>	Enter or change the pattern that FortiOS Carrier uses to match with carrier endpoints. The pattern can be a single carrier endpoint or consist of wildcards or Perl regular expressions that will match more than one carrier endpoint. Set <b>Pattern Type</b> to correspond to the pattern that you want to use.
<b>Action</b>	Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the carrier endpoint pattern:
<b>Pattern Type</b>	The type of pattern chosen.
<b>New Entry page</b>	
<b>Pattern</b>	Enter or change the pattern that FortiOS Carrier uses to match with carrier endpoints. The pattern can be a single carrier endpoint or consist of wildcards or Perl regular expressions that will match more than one carrier endpoint. Set <b>Pattern Type</b> to correspond to the pattern that you want to use.
<b>Action(s)</b>	<p>Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the carrier endpoint pattern:</p> <p>Action(s) can be:</p> <ul style="list-style-type: none"> <li>• None</li> <li>• Block</li> <li>• Exempt from mass MMS</li> <li>• Exempt from all scanning</li> </ul>
<b>Content Archive</b>	MMS messages from the carrier endpoint are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
<b>Pattern Type</b>	<p>Select a pattern type as one of Single Carrier Endpoint, Wildcard or Regular Expression.</p> <p>Wildcard and Regular Expression will match multiple patterns where Single Carrier Endpoint matches only one.</p>
<b>Enable</b>	Select to enable this carrier endpoint filter pattern.

## Message flood protection

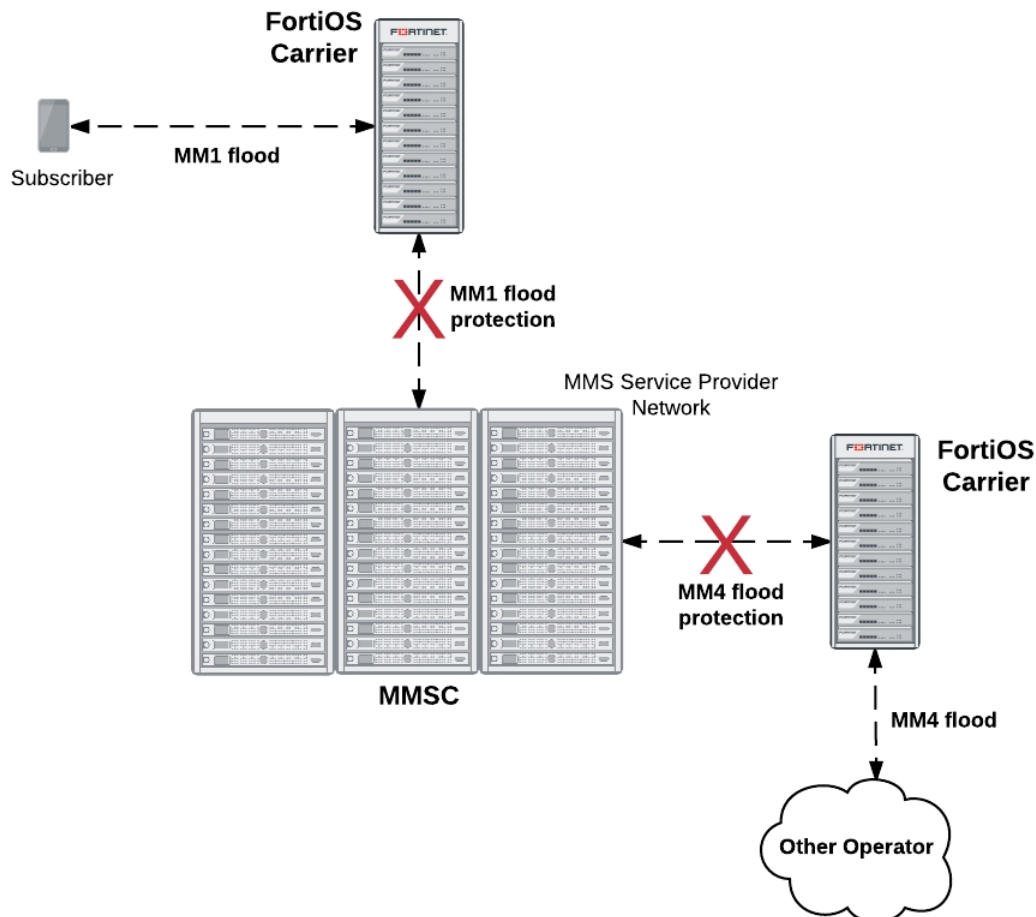

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse.

### Overview

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many

messages from the same subscriber to your MMSC.

### MM1 and MM4 flood protection

The FortiOS Carrier unit keeps track of the number of messages each subscriber sends for the length of time you specify. If the number of messages a subscriber sends exceeds the threshold, a configured action is taken. Possible actions are logging the flood, blocking or intercepting messages in the flood, archiving the flood messages, and sending an alert message to inform the administrator that the flood is occurring.

You can create three different thresholds to take different levels of action at different levels of activity.

With this highly configurable system, you can prevent subscribers from sending more messages than you determine is acceptable, or monitor anyone who exceeds the thresholds.

### Setting message flood thresholds

A message flood occurs when a single subscriber sends a volume of messages that exceeds the flood threshold you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected.

If a subscriber exceeds the message flood threshold and is blocked from sending more messages, any further attempts to send messages will re-start the block period. You must also enable logging for **MMS Scanning > Bulk Messages** in the Logging section of the MMS protection profile.

A subscriber is still able to receive messages while they are blocked from sending messages.

### Example

For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all messages blocked for half an hour (30 minutes).

Using this example, if the subscriber exceeds the flood threshold, they are blocked from sending message for 30 minutes. If the subscriber tries to send any message after 15 minutes, the message will be blocked and the block period will be reset again to 30 minutes. The block period must expire with no attempts to send a message. Only then will the subscriber be allowed to send more messages.

### To configure MM1 message flood threshold - web-based manager

1. Go to **Security Profiles > MMS Profile**.
2. Select **Create New**.
3. Enter `MM1_flood` for **Profile Name**.
4. Expand **MMS Bulk Email Filtering Detection**.
5. Enter the following information, and select **OK**.

MM1 (first column)	
<b>Enable</b>	Enable
<b>Message Flood Window</b>	60 minutes
<b>Message Flood Limit</b>	100
<b>Message Flood Block Time</b>	30 minutes
<b>Message Flood Action</b>	Block

### To configure MM1 message flood threshold - CLI

```
config firewall mms-profile
  edit profile_name
    config flood mm1
      set status1 enable
      set window1 60
      set limit1 100
      set action1 block
      set block-time1 30
    end
  end
end
```

The threshold values that you set for your network will depend on factors such as how busy your network is and the kinds of problems that your network and your subscribers encounter. For example, if your network is not too busy you may want to set message flood thresholds relatively high so that only an exceptional situation will exceed a flood threshold. Then you can use log messages and archived MMS messages to determine what caused the flood.

If your subscribers are experiencing problems with viruses that send excessive amounts of messages, you may want to set thresholds lower and enable blocking to catch problems as quickly as possible and block access to keep the problem from spreading.

### Flood actions

When the Carrier-enabled FortiGate unit detects a message flood, it can take any combination of the five actions that you can configure for the flood threshold. For detailed options, see Message Flood.

### Notifying administrators of floods

You can configure alert notifications for message floods by selecting the Alert Notification message flood action.

The FortiOS Carrier unit sends alert notifications to administrators using the MM1, MM3, MM4, or MM7 content interface. To send an alert notification you must configure addresses and other settings required for the content interface.

For example, to send notifications using the MM1 content interface you must configure a source MSISDN, hostname, URL, and port to which to send the notification. You can also configure schedules for when to send the notifications.

Finally you can add multiple MSISDN numbers to the MMS protection profile and set which flood thresholds to send to each MSISDN.

### Example — three flood threshold levels with different actions for each threshold

You can set up to three threshold levels to take different actions at different levels of activity.

The first example threshold records log messages when a subscriber's handset displays erratic behavior by sending multiple messages using MM1 at a relatively low threshold. The erratic behavior could indicate a problem with the subscriber's handset. For example, you may have determined for your network that if a subscriber sends more the 45 messages in 30 minutes that you want to record log messages as a possible indication or erratic behavior.

From the web-based manager in an MMS profile set message **Flood Threshold 1** to:

<b>Enable</b>	Selected
<b>Message Flood Window</b>	30 minutes
<b>Message Flood Limit</b>	45
<b>Message Flood Action</b>	Log

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config flood mm1
```

```

        set status1 enable
        set window1 30
        set limit1 45
        set action1 log
    end
end

```

Set a second higher threshold to take additional actions when a subscriber sends more that 100 messages in 30 minutes. Set the actions for this threshold to log the flood, archive the message that triggered the second threshold, and block the sender for 15 minutes.

From the web-based manager in an MMS profile set message **Flood Threshold 2** to:

<b>Enable</b>	Selected
<b>Message Flood Window</b>	30 minutes
<b>Message Flood Limit</b>	100
<b>Message Block Time</b>	15 minutes
<b>Message Flood Action</b>	Log, DLP archive First message only, Block

From the CLI:

```

config firewall mms-profile
  edit profile_name
    config flood mm1
      set status2 enable
      set window2 30
      set limit2 100
      set action2 block log archive-first
      set block-time2 15
    end
  end
end

```

Set the third and highest threshold to block the subscriber for an extended period and sand an administrator alert if the subscriber sends more than 200 messages in 30 minutes. Set the actions for this threshold to block the sender for four hours (240 minutes), log the flood, archive the message that triggered the third threshold, and send an alert to the administrator.

From the web-based manager in an MMS profile set message **Flood Threshold 3** to:

<b>Enable</b>	Selected
<b>Message Flood Window</b>	30 minutes
<b>Message Flood Limit</b>	200
<b>Message Block Time</b>	240 minutes
<b>Message Flood Action</b>	Log, Block, Alert Notification

Because you have selected the **Alert Notification** action you must also configure alert notification settings. For this example, the source MSISDN is 5551234—telephone number 555-1234. When administrators receive MMS messages from this MSISDN they can assume a message flood has been detected.

In this example, alert notifications are sent by the FortiOS Carrier unit to the MMSC using MM1. The host name of the MMSC is `mmscexample`, the MMSC URL is `/`, and the port used by the MMSC is 80. In this example, the alert notification window starts at 8:00am and extends for eight hours on weekdays (Monday-Friday) and the minimum interval between message flood notifications is two hours.

<b>Source MSISDN</b>	5551234
<b>Message Protocol</b>	MM1
<b>Hostname</b>	mmscexample
<b>URL</b>	/
<b>Port</b>	80
<b>Notifications Per Second Limit</b>	0
<b>Window Start Time</b>	8:00
<b>Window Duration</b>	8:00
<b>Day of Week</b>	Mon, Tue, Wed, Thu, Fri, Sat
<b>Interval</b>	2 hours

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config notification alert-flood-1
      set alert-src-msisdn 5551234
      set msg-protocol mm1
      set mmsc-hostname mmscexample
      set mmsc-url /
      set mmsc-port 80
      set rate-limit 0
      set tod-window-start 8:00
      set tod-window-duration 8:00
      set days-allowed monday tuesday wednesday thursday friday
      set alert-int 2
      set alert-int-mode hours
    end
```

You must also add the MSISDNs of the administrators to be notified of the message flood. In this example, the administrator flood threshold 3 alert notifications are sent to one administrator with MSISDN 5554321.

To add administrator's MSISDNs for flood threshold 3 from the web-based manager when configuring a protection profile, select **MMS Bulk Email Filtering Detection > Recipient MSISDN > Create New**.

<b>MSISDN</b>	5554321
<b>Flood Level 3</b>	Select

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config notif-msisdn
      edit 5554321
        set threshold flood-thresh-3
      end
    end
  end
```

## Notifying message flood senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver that cause a message flood. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around flood protection. For this reason, no notification is set to the sender or receiver.

However, FortiOS Carrier does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as message floods. For information about how FortiOS Carrier responds when message flood detection blocks a message, see [and MMS duplicate messages and message floods](#).

## Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (`m-send.conf`) to the sender — otherwise the sender's handset would keep retrying the message. The `m-send.conf` message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the MMSC and the MMSC sends the `m-send.conf` message.

You can customize the `m-send.conf` message by editing the **MM1 send-conf flood message** MM1 replacement message (from the CLI the `mm1-send-conf-flood` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted". To hide the fact that FortiOS Carrier is responding to a flood, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK":

```
config system replacemsg mm1 mm1-send-conf-flood
  set rsp-status ok
  set rsp-text "Message Sent OK"
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (`m-retrieve.conf`) to the sender (otherwise the sender's handset would keep retrying the message). The `m-retrieve.conf` message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the receiver, so the MMSC sends the `m-retrieve.conf` message.

You can customize the m-retrieve.conf message by editing the **MM1 retrieve-conf flood message** MM1 replacement message (from the CLI the `mm1-retr-conf-flood` replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-flood
    set subject "Message blocked"
    set message "Message temporarily blocked by carrier"
end
```

### Forward responses for MM4 message floods

When the FortiOS Carrier unit identifies an MM4 message as a flood message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4\_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4\_forward.res message is sent only when the MM4 message flood action is set to Block and the MM4-forward.req message requested a response. For more information, see and MMS duplicate messages and message floods.

You can customize the MM4\_forward.res message by editing the **MM4 flood message** MM4 replacement message (from the CLI the `mm4-flood` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted" (`err-content-not-accept`). To hide the fact that the FortiOS Carrier unit is responding to a flood, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK" for the MM4 message forward response

```
config system replacemsg mm4 mm4-flood
    set rsp-status ok
    set rsp-text "Message Forwarded OK"
end
```

### Viewing DLP archived messages

If **DLP Archive** is a selected message flood action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages, but you can configure the DLP archive setting to save only the first message that exceeds the threshold. This still provides a sample of the offending messages without requiring as much storage.

#### To select only the first message in a flood for DLP archiving - web-based manager

1. Go to **Security Profiles > MMS Profile**.
2. Edit an existing MMS Profile.
3. Expand the **MMS Bulk Email Filtering Detection** section, the **Message Flood** subsection, and the desired **Flood Threshold** subsection.
4. Next to **DLP Archive**, select **First message only** from the drop down menu.
5. Select **OK**.

### Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totaling the number of messages sent by each subscriber regardless

of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The Carrier-enabled FortiGate unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a **Block** action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

### Bypassing message flood protection based on user's carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from message flood protection. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns.

If you add a carrier endpoint pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier endpoints bypass message flood protection. This allows legitimate bulk messages, such as system outage notifications, to be delivered without triggering message flood protection.

For more information on carrier endpoints, see the User Authentication chapter of the FortiOS Handbook.

### Configuring message flood detection

To have the Carrier-enabled FortiGate unit check for message floods, you must first configure the flood threshold in an MMS profile, select the MMS profile in a security policy. All the traffic examined by the security policy will be checked for message floods according to the threshold values you set in the MMS profile.

#### Configure the MMS profile - web-based manager

1. Go to **Firewall Objects > MMS Profile**.
2. If you are editing an MMS profile, select the **Edit** icon of the MMS profile.  
If you are creating a new MMS profile, select **Create New** and enter a profile name.
3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Message Flood**.
5. Expand **Flood Threshold 1**.
6. Select the **Enable** check box for MM1 messages, MM4 messages, or both.
7. In the **Message Flood Window** field, enter the length of time the Carrier-enabled FortiGate unit will keep track of the number of messages each subscriber sends.  
If the Carrier-enabled FortiGate unit detects the quantity of messages specified in the **Message Flood Limit** sent during the number of minutes specified in the **Message Flood Window**, a message flood is in progress.
8. In the **Message Flood Limit** field, enter the number of messages required to trigger the flood.
9. In the **Message Flood Block Time** field, enter the length of time a user will be blocked from sending messages after causing the message flood.
10. Select the message flood actions the Carrier-enabled FortiGate unit will take when the message flood is detected.
11. Select **OK**.

### Configure the security policy - web-based manager

1. Go to **Policy**.
2. Select the **Edit** icon of the security policy that controls the traffic in which you want to detect message floods.
3. Select the **MMS Profile** check box to enable the use of a protection profile.
4. Select the MMS protection profile from the list.
5. Select **OK**.

### Sending administrator alert notifications

When message floods are detected, the Carrier-enabled FortiGate unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the message flood action. Each message flood threshold can be configured separately.

### Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 message floods. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
- **submit.REQ** to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
- **deliver.REQ** to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

For more information, see MMS notifications.

**To configure administrator alert notifications - web-based manager**

1. Go to **Firewall Objects > MMS Profile** and edit or add a new MMS protection profile.
2. Expand **MMS Bulk Email Filtering Detection**.  
There are three message flood thresholds.
3. Expand the threshold that you want to configure alert notification for.
4. For **Message Flood Action**, select the **Alert Notification** check box. Alert notification options appear.
5. For the **Source MSISDN**, enter the MSISDN from which the alert notification message will be sent.
6. Select the Message Protocol the alert notification will use: **MM1**, **MM3**, **MM4**, or **MM7**.
7. Add the information required by FortiOS Carrier to send messages using the selected message protocol:
8. For **Notifications Per Second Limit**, enter the number of notifications to send per second.  
Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.
9. If required, change **Window Start Time** and **Window Duration** configure when the FortiOS Carrier unit sends alert notifications.  
By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.  
  
For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.  
  
You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.
10. For **Day of Week**, select the days of the week to send notifications.  
For example, you may only want to send alert notifications on weekends for higher thresholds.
11. In the **Interval field**, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.  
All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

**Configuring who to send alert notifications to**

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the message flood threshold that triggers sending notifications to this MSISDN.

**To configure the alert notification recipients - web-based manager**

1. Go to **Firewall Objects > MMS Profile**.
2. Select the **Edit** icon of the MMS profile in which you want to configure the alert notification recipients.
3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Recipient MSISDN**.
5. Select **Create New**.
6. In the **New MSISDN** window, enter the MSISDN to use for flood threshold alert notification.
7. Select the duplicate thresholds at which to send alert notifications to the MSISDN.

For the flood threshold to be able to send an alert notification to the MSISDN, the alert notification action must be enabled and configured within the flood threshold.

---

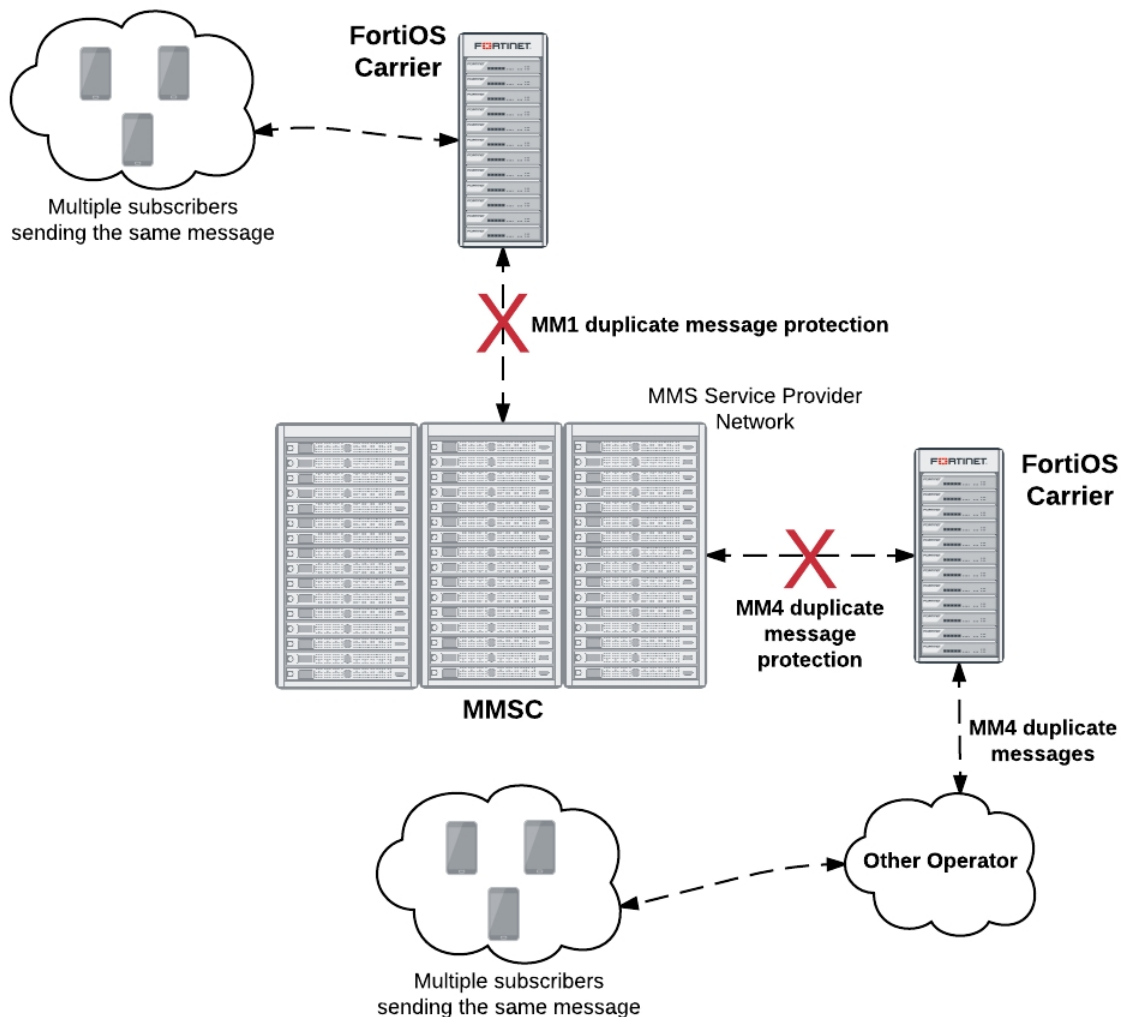

## Duplicate message protection

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or other unwanted messages. Often, the same message will be sent by multiple subscribers. The message can be spam, viral marketing, or worm-generated messages. MMS duplicate prevention can help prevent this type of abuse by keeping track of the messages being sent.

### Overview

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC. This can help prevent a potential flood that would otherwise become widespread between carriers.

### MM1 and MM4 duplicate message protection

The FortiOS Carrier unit keeps track of the sent messages. If the same message appears more often than the threshold value you configure, then action is taken. Possible actions are logging the duplicates, blocking or intercepting duplicate messages, archiving the duplicate messages, and sending an alert to inform an administrator that duplicates are occurring.

With this highly configurable system, you can prevent the transmission of duplicate messages when there are more than you determine is acceptable.

For detailed configuration options, see Duplicate Message.

### Using message fingerprints to identify duplicate messages

The Carrier-enabled FortiGate unit detects duplicates by keeping a record of all the messages travelling on the network and comparing new messages to those that have already been sent.

Rather than save the messages, the FortiOS carrier creates a checksum using the message body and subject. This serves as a fingerprint to identify the message. If another message with the same message body and subject appears, the fingerprint will also be the same and the Carrier-enabled FortiGate unit will recognize it as a duplicate.

By creating and saving message fingerprints instead of saving the messages, the Carrier-enabled FortiGate unit can save resources and time.

### Messages from any sender to any recipient

Duplicate message detection will detect duplicate messages regardless of the sender or recipient. To do this, message fingerprints are generated using only the message body and subject. The sender, recipient, and other header information is not included.

If multiple messages appear with the same subject and message body, the Carrier-enabled FortiGate unit will recognize them as being the same.

### Setting duplicate message thresholds

The FortiOS Carrier recognizes all duplicate messages, but it will take action when it detects a volume of duplicate messages that exceed the duplicate threshold you set. The threshold defines the maximum number of duplicate messages allowed, the period during which the messages are considered, and the length of time the duplicate message can not be sent by anyone.

For example, you may determine that once a duplicate message is sent more than 300 times in an hour, any attempt to send the same duplicate message will be blocked for 30 minutes.

If a particular duplicate message exceeds the duplicate message threshold and is blocked, any further attempts to send the same message will re-start the block period.

Using the example above, if the duplicate message count exceeds the duplicate threshold, any attempt to send a copy of the duplicate message will be blocked for 30 minutes. If a subscriber tries to send a copy of the message after waiting 15 minutes, the message will be blocked and the block period will be reset to 30 minutes. The block period must expire with no attempts to send a duplicate message. Only then will a subscriber be allowed to send the message. Non-duplicate messages will not reset the block period.

### Duplicate message actions

When the Carrier-enabled FortiGate unit detects that a duplicate message has exceeded duplicate threshold, it can take any combination of the five actions you configure for the duplicate threshold.

Action	Description
Log	Add a log entry indicating that a duplicate message event has occurred. You must also enable logging for <b>MMS Scanning &gt; Bulk Messages</b> in the <b>Logging</b> section of the MMS protection profile.
DLP Archive	

Action	Description
<b>All messages</b>	Save all the messages that exceed the duplicate threshold in the DLP archive.
<b>First message only</b>	Save the first message to exceed the duplicate threshold in the DLP archive. Subsequent messages that exceed the duplicate threshold will not be saved.
<b>Intercept</b>	Messages that exceed the duplicate threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message is also quarantined for later examination. If the quarantine of intercepted messages is disabled, the <b>Intercept</b> action has no effect.
<b>Block</b>	Messages that exceed the duplicate threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each blocked message is quarantined for later examination.
<b>Alert Notification</b>	If the duplicate threshold is exceeded, the Carrier-enabled FortiGate unit will send an MMS duplicate message notification message.

### Notifying duplicate message senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver of duplicate messages. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around duplicate message protection. For this reason, no notification is set to the sender or receiver.

However, the FortiOS Carrier unit does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as duplicate messages. For information about how FortiOS Carrier responds when message flood detection blocks a message, see and MMS duplicate messages and message floods.

### Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (m-send.conf) to the sender (otherwise the sender's handset would keep retrying the message). The m-send.conf message is sent only when the MM1 duplicate message action is set to Block. For other duplicate message actions the message is actually delivered to the MMSC and the MMSC sends the m-send.conf message.

You can customize the m-send.conf message by editing the **MM1 send-conf duplicate message** MM1 replacement message (from the CLI the `mm1-send-conf-dupe` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted". To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK":

```
config system replacemsg mm1 mm1-send-conf-dupe
    set rsp-status ok
    set rsp-text "Message Sent OK"
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (m-retrieve.conf) to the sender (otherwise the sender's handset would keep retrying). The m-retrieve.conf message is sent only when the MM1duplicate message action is set to Block. For other message flood actions the message is actually received by the receiver, so the MMSC sends the m-retrieve.conf message.

You can customize the m-retrieve.conf message by editing the **MM1 retrieve-conf duplicate message** MM1 replacement message (from the CLI the mm1-retr-conf-dupe replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-dupe
    set subject "Message blocked"
    set message "Message temporarily blocked by carrier"
end
```

### Forward responses for duplicate MM4 messages

When the FortiOS Carrier unit identifies an MM4 message as a duplicate message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4\_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4\_forward.res message is sent only when the MM4 duplicate message action is set to Block and the MM4-forward.req message requested a response. For more information, see and MMS duplicate messages and message floods.

You can customize the MM4\_forward.res message by editing the **MM4 duplicate message** MM4 replacement message (from the CLI the mm4-dupe replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted" (err-content-not-accept). To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Forwarded OK":

```
config system replacemsg mm4 mm4-dupe
    set rsp-status ok
    set rsp-text "Message Forwarded OK"
end
```

### Viewing DLP archived messages

If **DLP Archive** is a selected duplicate message action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages but you can configure the DLP archive setting to save only the first message that exceeds the threshold. See Viewing DLP archived messages.

### Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totalling the number of messages sent by each subscriber

regardless of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The Carrier-enabled FortiGate unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a **Block** action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

### Bypassing duplicate message detection based on user's carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from duplicate message detection. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns. If you add a carrier endpoint pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier endpoints bypass duplicate message detection. For more information about endpoints, see FortiOS Handbook User Authentication guide.

### Configuring duplicate message detection

To have the Carrier-enabled FortiGate unit check for duplicate messages, configure the duplicate threshold in an MMS profile, and select the MMS profile in a security policy.

All traffic matching the security policy will be checked for duplicate messages according to the settings in the MMS profile.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

---

The modular nature of the profiles allows you great flexibility in how you configure the scanning options. MMS profiles can be used in any number of policies, with different GTP profiles.

In a complex configuration, there may be many security policies, each with a different MMS profile. For a simpler network, you may have many security policies all using the same MMS profile.

### Sending administrator alert notifications

When duplicate messages are detected, the Carrier-enabled FortiGate unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the duplicate message action. Each duplicate message threshold can be configured separately.

### Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 duplicate messages. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
- **submit.REQ** to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
- **deliver.REQ** to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

#### To configure administrator alert notifications - web-based manager

1. Go to **Security Profiles > MMS Profile** and edit or add a new MMS protection profile.
2. Expand **MMS Bulk Email Filtering Detection**.  
There are three duplicate message thresholds.
3. Expand the threshold that you want to configure alert notification for.
4. For **Duplicate Message Action**, select the **Alert Notification** check box. Alert notification options appear.
5. For the **Source MSISDN**, enter the MSISDN from which the alert notification message will be sent.
6. Select the Message Protocol the alert notification will use: **MM1**, **MM3**, **MM4**, or **MM7**.
7. Add the information required by FortiOS Carrier to send messages using the selected message protocol:
8. For **Notifications Per Second Limit**, enter the number of notifications to send per second.  
Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.
9. If required, change **Window Start Time** and **Window Duration** configure when the FortiOS Carrier unit sends alert notifications.  
By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.  
  
For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.  
  
You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.
10. For **Day of Week**, select the days of the week to send notifications.  
For example, you may only want to send alert notifications on weekends for higher thresholds.
11. In the **Interval field**, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.

All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

### Configuring who to send alert notifications to

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the duplicate threshold that triggers sending notifications to this MSISDN.

#### To configure the alert notification recipients - web-based manager

1. Go to **Security Profiles > MMS Profile**.
2. Select the **Edit** icon of the MMS profile in which you want to configure the alert notification recipients.
3. Expand **MMS Bulk Email Filtering Detection**.
4. Expand **Recipient MSISDN**.
5. Select **Create New**.
6. In the **New MSISDN** window, enter the MSISDN to use for duplicate threshold alert notification.

Select the duplicate thresholds at which to send alert notifications to the MSISDN.

For the duplicate threshold to be able to send an alert notification to the MSISDN, the duplicate message threshold alert notification action must be enabled and configured.

## Employing MMS Security features

FortiOS Carrier includes all the Security features of FortiOS with extra features specific to MMS carrier networks.

This section includes:

### Why scan MMS messages for viruses and malware?

The requirement for scanning MM1 content comes from the fact that MMS is an increasingly popular technique for propagating malware between mobile devices.

#### Example: COMMWARRIOR

This is a virus for Series 60 type cell phones, such as Nokia, operating Symbian OS version 6 [or higher]. The object of the virus is to spread to other phones using Bluetooth and MMS as transport avenues. The targets are selected from the contact list of the infected phone and also sought via Bluetooth searching for other Bluetooth-enabled devices (phones, printers, gaming devices etc.) in the proximity of the infected phone.

This virus is more than a proof of concept - it has proven successfully its ability to migrate from a zoo collection to being in-the-wild. Currently, this virus is being reported in over 18 different countries around Europe, Asia and North America.

When the virus first infects a cell phone, a prompt is displayed asking the recipient if they want to install "Caribe". Symptoms of an infected phone may include rapid battery power loss due to constant efforts by the virus to spread to other phones via a Bluetooth seek-and-connect outreach.

The following variants among others are currently scanned by the FortiOS Carrier devices, in addition to more signatures that cover all known threats.

- **SymbOS/COMWAR.V10B!WORM**

- Aliases: SymbOS.Commwarrior.B, SymbOS/Commwar.B, SymbOS/Commwar.B!wm, SymbOS/Commwar.B-net, SymbOS/Commwarrior.b!sis, SymbOS/Comwar.B, SymbOS/Comwar.B!wm, SymbOS/Comwar.B-wm, SYMBOS\_COMWAR.B, SymbOS/Comwar.1.0.B!wormSYMBOS/COMWAR.V10B.SP!WORM [Spanish version]
- First Discovered In The Wild: July 04, 2007
- Impact Level: 1
- Virus Class: Worm
- Virus Name Size: 23,320

- **SymbOS/Commwar.A!worm**

- Aliases: Commwarrior-A, SymbOS.Commwarrior.A [NAV], SymbOS/Commwar.A-net, SymbOS/Commwar\_ezboot.A-ne, SymbOS/Comwar.A, SymbOS/Comwar.A-wm, SYMBOS\_COMWAR.A [Trend]
- First Discovered In The Wild: May 16 2005
- Impact Level: 1
- Virus Class: Worm
- Virus Name Size: 27,936
- SymbOS/Commwarriie.C-wm
- Aliases: None
- First Discovered In The Wild: Oct 17 2005
- Impact Level: 1
- Virus Class: File Virus
- Virus Name Size: None

For the latest list of threats Fortinet devices detect, visit the FortiGuard Center.

## MMS virus scanning

You can use MMS virus scanning to scan content contained within MMS messages for viruses. FortiOS Carrier virus scanning can be applied to the MM1, MM3, MM4, and MM7 interfaces to detect and remove content containing viruses at many points in an MMS network. Perhaps the most useful interface to apply virus scanning would be the MM1 interface to block viruses sent by mobile users before they get into the service provider network.

To go to MMS virus scanning, go to **Security Profiles MMS Profile**, select an existing or create a new profile, and expand **MMS Scanning**. See MMS scanning options.

This section includes:

- [MMS virus monitoring](#)
- [MMS virus scanning blocks messages \(not just attachments\)](#)
- [Scanning MM1 retrieval messages](#)
- [Configuring MMS virus scanning](#)
- [Removing or replacing blocked messages](#)
- [Carrier Endpoint Block](#)
- [MMS Content Checksum](#)
- [Passing or blocking fragmented messages](#)
- [Client comforting](#)
- [Server comforting](#)
- [Handling oversized MMS messages](#)

### MMS virus monitoring

To enable MMS virus monitoring, expand **MMS Scanning** and enable **Monitor only** for the selected MMS types.

This feature causes the FortiOS Carrier unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Selecting this option enables reporting on viruses and other problems in MMS traffic without affecting users.

### MMS virus scanning blocks messages (not just attachments)

To enable MMS virus scanning, expand **MMS Scanning** and enable **Virus Scan** for the selected MMS types.

Because MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configurations also apply to MM1 and MM7 scanning. See

MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configurations also apply to MM3 and MM4 scanning.

The message contents will be scanned for viruses, matched against the file extension blocking lists and scanned for banned words. All these items will be configured via the standard GUI interfaces available for the other protocols and will be controlled at the protection profile level with new options specifically for the MM1 messages.

The FortiOS Carrier unit extracts the sender's Mobile Subscriber Integrated Services Digital Network Number (MSISDN) from the HTTP headers if available. The `POST` payload will be sent to the scan units which will parse the MMS content and scan each message data section. If any part of the data is to be blocked, the proxy will be informed, the connection to the MMSC will be reset and the Carrier-enabled FortiGate unit will return an `HTTP 200 OK` message with an `m-send-conf` payload to the client to prevent a retry. Finally the appropriate logging, alert, and replacement message events will be triggered.

For client notification, the `x-mms-response-status` and `x-mms-response-text` fields can also be customized as required.

### Scanning MM1 retrieval messages

To scan MM1 retrieval messages, expand **MMS Scanning** and select **Scan MM1 message retrieval**.

Select to scan message retrievals that use MM1. If you enable **Virus Scan** for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.

### Configuring MMS virus scanning

To configure MMS virus scanning, expand **MMS Scanning** and enable **Virus Scan**.

Once applied to a security policy, the MMS protection profile will then perform virus scans on all traffic accepted by that policy.

### Removing or replacing blocked messages

To remove blocked messages, expand **MMS Scanning** and select **Remove Blocked** for the selected MMS types.

Select **Remove Blocked** remove blocked content from each protocol and replace it with the replacement message. If FortiOS Carrier is to preserve the length of the message when removing blocked content, as may occur when billing is affected by the length of the message, select **Constant**.

If you only want to monitor blocked content, select **Monitor Only**.

### Carrier Endpoint Block

A carrier endpoint defines a specific client on the carrier network. Typically the client IP address is used to identify the client, however on a carrier network this may be impractical when the client is using a mobile device. Other identifying information such as the MSISDN number is used instead.

This information can be used to block a specific endpoint on the network. Reasons for blocking may include clients whose accounts have expired, clients from another carrier, clients who have sent malicious content (phishing, exploits, viruses, etc), or other violations of terms of use.

### Enabling carrier endpoint blocking

To enable carrier endpoint blocking you first need to create a carrier endpoint filter list, and then enable it.

#### To enable carrier endpoint blocking - web-based manager

1. Create a carrier endpoint filter list.
2. Go to **Security Profiles > MMS Profile**.
3. Select **Create New**, or select an existing profile to edit and select **Edit**.
4. Expand MMS Scanning.
5. Select one or more types of MMS messaging to enable endpoint blocking on.
6. Select the carrier endpoint filter list to use in matching the endpoints to be blocked.

In MMS Profile, endpoints can only be blocked.

---

### Create a carrier endpoint filter list

A carrier endpoint filter list contains one or more carrier endpoints to match. When used in MMS scanning entries in the filter list that are matched are blocked.

You can configure multiple filter lists for different purposes and groups of clients, such as blocking clients, clients with different levels of service agreements, and clients from other carriers. See Carrier endpoint filter lists configuration settings.

#### To create a carrier endpoint filter list - web-based manager

1. Go to **Security Profiles > Carrier Endpoint Filter Lists**.
2. Select **Create New**.
3. Enter a descriptive name for the filter list, such as `blocked_clients` or `CountryX_clients`, and select **OK**.
4. Select **Create New** to add one or more entries to the list.
5. Select **OK** to return to display the list of filter lists.

## Configuring endpoint filter list entries

For each single endpoint or group of endpoints have part of their identifying information in common, you create an entry in the endpoint filter list.

For example a `blocked_clients` filter list may include entries for single endpoints added as each one needs to be blocked and a group of clients from a country that does not allow certain services.

### To configure an endpoint filter list entry - web-based manager

1. Select **Create New**.
2. Enter the following information and select **OK**.

<b>Name</b>	Name of endpoint filter list. Select this name in an MMS protection profile.
<b>Comments</b>	Optional description of the endpoint filter list.
<b>Check/Uncheck All</b>	<p>Select the check box to enable all endpoint patterns in the MMS filter list.</p> <p>Clear the check box to disable all entries on the MMS filter list.</p> <p>You can also select or clear individual check boxes to enable or disable individual endpoint patterns.</p>
<b>Pattern</b>	The pattern that FortiOS Carrier uses to match with endpoints. The pattern can be a single endpoint or consist of wildcards or Perl regular expressions that will match more than one endpoint. For more on wildcard and regular expressions, see Using wildcards and Perl regular expressions in the UTM guide.
<b>Action</b>	<p>Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the endpoint pattern:</p> <p><b>None</b> - No action is taken.</p> <p><b>Block</b> - MMS messages from the endpoint are not delivered and FortiOS Carrier records a log message.</p> <p><b>Exempt from mass MMS</b> - MMS messages from the endpoint are delivered and are exempt from mass MMS filtering. Mass MMS filtering is configured in MMS protection profiles and is also called MMS Bulk Email Filtering and includes MMS message flood protection and MMS duplicate message detection. A valid use of mass MMS would be when a service provider notifies customers of a system-wide event such as a shutdown.</p> <p><b>Exempt from all scanning</b> - MMS messages from the endpoint are delivered and are exempt from all MMS protection profile scanning.</p>

<b>Content Archive</b>	MMS messages from the endpoint are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
<b>Intercept</b>	MMS messages from the endpoint are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.
<b>Pattern Type</b>	The pattern type: <b>Wildcard</b> , <b>Regular Expression</b> , or <b>Single Endpoint</b> .
<b>Enable</b>	Select to enable this endpoint filter pattern.

### Blocking network access based on endpoints

You can use endpoint IP filtering to block traffic from source IP addresses associated with endpoints. You can also configure FortiOS Carrier to record log messages whenever endpoint IP filtering blocks traffic. Endpoint IP filtering blocks traffic at the IP level, before the traffic is accepted by a security policy.

To configure endpoint IP filtering, go to **Security Profiles > IP Filter** and add endpoints to the IP filter list. For each endpoint you can enable or disable both blocking traffic and logging blocked traffic.

You cannot add endpoint patterns to the endpoint IP filter list. You must enter complete and specific endpoints that are valid for your network.

The only action available is block. You cannot use endpoint IP filtering to exempt endpoints from IP filtering or to content archive or quarantine communication sessions.

FortiOS Carrier looks in the current user context list for the endpoints in the IP filter list and extracts the source IP addresses for these endpoints. Then any communication session with a source IP address that matches one of these IP addresses is blocked at the IP level, before the communication session is accepted by a security policy.

FortiOS Carrier dynamically updates the list of IP addresses to block as the user context list changes. Only these updated IP addresses are blocked by endpoint IP filtering.

For information about the carrier endpoints and the user context list, including how entries are added to and removed from this list.

### MMS Content Checksum

The MMS content checksum feature attempts to match checksums of known malicious MMS messages, and on a successful match it will be blocked. The checksums are applied to each part of the message—attached files and message body have separate checksums. These checksums are created with CRC-32, the same method as FortiAnalyzer checksums.

For example, if an MMS message contains a browser exploit in the message body, you can add the checksum for that message body to the list, and future occurrences of that exact message will be blocked. Content will be replaced by the content checksum block notification replacement message for that type of MMS message, and if it is enabled the event will be logged.

One possible implementation would be to configure all .sis files to be intercepted. When one is found to be infected or malicious it would be added to the MMS content checksum list.

To use this feature a list of one or more malicious checksums must be created and then the feature is enabled using that list. For a detailed list of options, see MMS Content Checksum.

### To configure an MMS content checksum list

1. Go to **Security Profiles > MMS Content Checksum**.
2. Select **Create New**.
3. Enter a name for the list of checksums, and select **OK**.  
You are taken to the edit screen for that new list.
4. Select **Create New** to add a checksum.
5. Enter the **Name** and **Checksum**, and select **OK**.  
The checksum is added to the list.

To add more checksums to the list, repeat steps 4 and 5.

To remove a checksum from the list you can either delete the checksum or simply disable it and leave it in the list.

To enable MMS content checksums, expand **MMS Scanning** and select **MMS Content Checksum** for the selected MMS types. Select the checksum list to match.

### Passing or blocking fragmented messages

Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 messages are blocked.

The **Interval** is the time in seconds before client comforting starts after the download has begun, and the time between sending subsequent data.

The **Amount** is the number of bytes sent by client or server comforting at each interval.

### Client comforting

In general, client comforting is available for MM1 and MM7 messaging and provides a visual display of progress for web page loading or HTTP or FTP file downloads. Client comforting does this by sending the first few packets of the file or web page being downloaded to the client at configured time intervals so that the client is not aware that the download has been delayed. The client is the web browser or FTP client. Without client comforting, clients and their users have no indication that the download has started until the Carrier-enabled FortiGate unit has completely buffered and scanned the download. During this delay users may cancel or repeatedly retry the transfer, thinking it has failed.

The appearance of a client comforting message (for example, a progress bar) is client-dependent. In some instances, there will be no visual client comforting cue.

During client comforting, if the file being downloaded is found to be infected, then the Carrier-enabled FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead the download stops, and the user is left with a partially downloaded file.

If the user tries to download the same file again within a short period of time, then the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a

notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting can send unscanned (and therefore potentially infected) content to the client. Only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

### MM1 and MM7 client comforting steps

Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.

The following steps show how client comforting works for a download of a 1 Mbyte file with the client comforting interval set to 20 seconds and the client comforting amount set to 512 bytes.

1. The client requests the file.
2. The Carrier-enabled FortiGate unit buffers the file from the server. The connection is slow, so after 20 seconds about one half of the file has been buffered.
3. The Carrier-enabled FortiGate unit continues buffering the file from the server, and also sends 512 bytes to the client.
4. After 20 more seconds, the FortiGate unit sends the next 512 bytes of the buffered file to the client.
5. When the file has been completely buffered, the client has received the following amount of data:  
$$ca * (T/ci) \text{ bytes} == 512 * (40/20) == 512 * 2 == 1024 \text{ bytes,}$$
where *ca* is the client comforting amount, *T* is the buffering time and *ci* is the client comforting interval.
6. If the file does not contain a virus, the Carrier-enabled FortiGate unit sends the rest of the file to the client. If the file is infected, the FortiGate closes the data connection but cannot send a message to the client.

### Server comforting

Server comforting can be selected for each protocol.

Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for FortiOS Carrier to buffer and scan large `POST` requests from slow clients.

The **Interval** is the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.

The **Amount** is the number of bytes sent by client or server comforting at each interval.

### Handling oversized MMS messages

Select **Block** or **Pass** for files and email messages exceeding configured thresholds for each protocol.

The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.

## Sender notifications and logging

In most cases you will notify the sender that they are causing problems on the network — either by sending malware content, flooding the network, or some other unwanted activity. The notification assumes the sender is unaware of their activity and will stop or correct it when notified.

However, senders who are notified may use this information to circumvent administration's precautions. For example if flood notification is set to 1000 messages per minute, a notified user may simply reduce their message to 990 messages per minute if this flood is intentional. For this reason, not all problems include sender notifications.

There are two methods of notifying senders:

- [MMS notifications](#)
- [Replacement messages](#)

And three details to consider for logging and notifying administrators:

- [Logging and reporting](#)
- [MMS logging options](#)
- [SNMP](#)

## MMS notifications

MMS notifications enable you to customize notifications for many different situations and differently for all the supported MMS message protocols — MM1, MM3, MM4, and MM7.

MMS notification types include:

- Content Filter
- File Block
- Carrier Endpoint Block
- Flood
- Duplicate
- MMS Content Checksum
- Virus Scan

**Day of Week**, **Window start time** and **Window Duration** define what days and what time of day alert notifications will be sent. This allows you to control what alerts are sent on weekends. It also lets you control when to start sending notifications each day. This can be useful if system maintenance is performed at the same time each night — you might want to start alert notifications after maintenance has completed. Another reason to limit the time alert messages are sent could be to limit message traffic to business hours.

## Replacement messages

FortiGate units send replacement messages when messages or content is blocked, quarantined, or otherwise diverted from the receiver. In its place a message is sent to notify the receiver what happened.

With FortiOS Carrier MMS replacement messages, send and receive message types are supported separately and receive their own custom replacement messages. This allows the network to potentially notify both the sender and receiver of the problem.

For example the replacement message **MM1 send-req file block message** is sent to the device that sent one or more files that were banned. The default message that is sent is `This device has sent %%NUM_MSG%% messages containing banned files in the last %%DURATION%% hours. The two variables are replaced by the appropriate values.`

Replacement messages are not as detailed or specific as MMS notifications, but they are also not as complicated to configure. They are also useful when content has been removed from an MMS message that was still delivered.

## Logging and reporting

With each virus infection, or file block, a syslog message is generated. The format of this syslog message is similar to:

```
2005-09-22 19:15:47 deviceid=FGT5001ABCDEF1234 logid=0211060ABC type=virus
  subtype=infected level=warning src=10.1.2.3 dst=10.2.3.4 srcintf=port1 dstintf=port2
  service=mm1 status=blocked from="<sending MSISDN>" to="<receiving MSISDN>"
```

```
file="eicar.com.txt" virus="EICAR_TEST_FILE" msg="The file eicar.com.txt is infected
with EICAR_TEST_FILE. ref
http://www.fortinet.com/VirusEncyclopedia/search/encyclopediaSearch.do?method=quickSea
rchDirectly&virusName=EICAR_TEST_FILE"
```

Note that the **from** and **to** fields are samples and not real values.

## MMS logging options

You can enable logging in an MMS protection profile to write event log messages when the MMS protection profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS protection profile logging options to write an event log message every time a virus is detected.

To record these log messages you must first configure how the FortiOS Carrier unit stores log messages.

To configure MMS content archiving, go to **Security Profiles > MMS Profile**. Select **Create New** or select the **Edit** icon beside an existing profile. Expand **MMS Bulk AntiSpam Detection > Logging**. Complete the fields as described in the following table and select **OK**. For more a detailed list of options, see Logging.

## SNMP

A simple SNMP trap will be generated to inform the operators' alerting system that a virus has been detected. This SNMP trap could contain the sending and receiving MSISDN, however the initial solution would reflect the current behavior, i.e. only the fact that a virus has been detected will be communicated.

## MMS content-based Antispam protection

Expand **MMS Scanning** and select **Content Filter** in an MMS protection profile to create content filter black/white lists that block or allow MMS messages based on the content of the message.

## Overview

A school computer lab may block age-inappropriate content. A place of business may block unproductive content. A public access internet cafe may block offensive and graphic content. Each installation has its own requirements for what content needs to be blocked, and in what language.

FortiOS Carrier provides the ability to create custom local dictionaries, black lists, and white lists in multiple languages enables you to protect your customers from malicious content around the world.

## Configurable dictionary

You can create a dictionary of configurable terms and phrases using the CLI. The text of MMS messages will be searched for these terms and phrases. Add content filter lists that contain content that you want to match in MMS messages. For every match found, a score is added. If enough matches are found to set the total score above the configured threshold, the MMS message is blocked.

You can add words, phrases, wild cards and Perl regular expressions to create content patterns that match content in MMS messages. For more on wildcard and regular expressions, see Using wildcards and Perl regular expressions in the UTM guide.

For each pattern you can select **Block** or **Exempt**.

- Block adds an antispam black list pattern. A match with a block pattern blocks a message depending on the score of the pattern and the content filter threshold.

- Exempt adds an antispam white list pattern. A match with an exempt pattern allows the message to proceed through the FortiOS Carrier unit, even if other content patterns in the same content filter list would block it.

If a pattern contains a single word, the FortiOS Carrier unit searches for the word in MMS messages. If the pattern contains a phrase, the FortiOS Carrier unit searches for all of the words in the phrase. If the pattern contains a phrase in quotation marks, the FortiOS Carrier unit searches for the whole phrase.

You can create patterns with Simplified Chinese, Traditional Chinese, Cyrillic, French, Japanese, Korean, Spanish, Thai, or Western character sets.

## Black listing

Black listing is the practice of banning entries on the list. For example if an IP address continuously sends viruses, it may be added to the black list. That means any computers that consult that list will not communicate with that IP address.

Sometimes computers or devices can be added to black lists for a temporary problem, such as a virus that is removed when notified. However, as a rule short of contacting the administrator in person to manually be removed from the black list, users have to wait and they generally will be removed after a period without problem.

## White listing

White listing is the practice of adding all critical IP addresses to a list, such as company email and web servers. Then if those servers become infected and start sending spam or viruses, those servers are not blocked. This allows the critical traffic through, even if there might be some malicious traffic as well. Blocking all traffic from your company servers would halt company productivity.

## Scores and thresholds

Each content pattern includes a score. When a MMS message is matched with a pattern the score is recorded. If a message matches more than one pattern or matches the same pattern more than once, the score for the message increases. When the total score for a message equals or exceeds the threshold the message is blocked.

The default score for a content filter list entry is 10 and the default threshold is 10. This means that by default a message is blocked by a single match. You can change the scores and threshold so that messages can only be blocked if there are multiple matches. For example, you may only want to block messages that contain the phrase "example" if it appears twice. To do this, add the "example" pattern, set action to block and score to 5. Keep the threshold at 10. If "example" is found twice or more in a message the score adds up 10 (or more) and the message is blocked.

## Configuring content-based antispam protection

### To apply content-based antispam protection - CLI

```
config webfilter content
  edit <filter_table_number>
    set name <filter_table_name>
    config entries
      edit <phrase or regexp you want to block>
        set action {block | exempt}
        set lang <phrase language>
        set pattern-type {wildcard | regexp}
        set score <phrase score>
        set status {enable | disable}
      end
    end
  end
```

end

## Configuring sender notifications

When someone on the MMS network sends an MMS message that is blocked, in most cases you will notify the sender. Typically an administrator is notified in addition to the sender so action can be taken if required. There are two types of sender notifications available in FortiOS Carrier: MMS notifications, and Replacement Messages.

### MMS notifications

MMS notifications to senders are configured in **Security Profiles > MMS Profile**, under MMS Notifications.

In this section you can configure up to four different notification recipients for any combination of MM1/3/4/7 protocol MMS messages. Also for MM7 messages the message type can be `submit.REQ` or `deliver.REQ`.

Useful settings include:

- delay in message based on notification type
- limit on notifications per second to prevent a flood
- schedules for notifications
- log in details for MM7 messages.

For more information on MMS notifications, see Notifying message flood senders and receivers and MMS Notifications.

### Replacement messages

Replacement messages are features common to both FortiOS and FortiOS Carrier, however FortiOS Carrier has additional messages for the MMS traffic.

While each MMS protocol has its own different replacement messages, the one common to all MMS protocols is the **MMS blocked content replacement message**. This is the message that the receiver of the message sees when their content is blocked.

## MMS DLP archiving

You can use DLP archiving to collect and view historical logs that have been archived to a FortiAnalyzer unit or the FortiGuard Analysis and Management service. DLP archiving is available for FortiAnalyzer when you add a FortiAnalyzer unit to the FortiOS Carrier configuration. The FortiGuard Analysis and Management server becomes available when you subscribe to the FortiGuard Analysis and Management Service.

You can configure full DLP archiving and summary DLP archiving. Full DLP archiving includes all content, for example, full email DLP archiving includes complete email messages and attachments. Summary DLP archiving includes just the meta data about the content, for example, email message summary records include only the email header.

You can archive MM1, MM3, MM4, and MM7 content.

### Configuring MMS DLP archiving

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. For each protocol you can archive just session metadata (**Summary**), or metadata and a copy of the associated file or message (**Full**).

In addition to MMS protection profile DLP archive options you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select **DLP archiving** for carrier endpoint patterns in a **Carrier Endpoint List** and select the **Carrier Endpoint Block** option in the **MMS Scanning** section of an MMS Protection Profile

FortiOS Carrier only allows one sixteenth of its memory for transferring content archive files. For example, for Carrier-enabled FortiGate units with 128 MB RAM, only 8 MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

#### To configure MMS DLP archiving - web-based manager

1. Go to **Security Profiles > MMS Profile**.
2. Select **Create New** or select the **Edit** icon beside an existing profile.
3. Expand **MMS Bulk AntiSpam Detection > Content Archive**.
4. Complete the fields as described in DLP Archive options.
5. Select **OK**.

#### Viewing DLP archives

You can view DLP archives from the Carrier-enabled FortiGate unit web-based manager. Archives are historical logs that are stored on a log device that supports archiving, such as a FortiAnalyzer unit.

These logs are accessed from either **Log & Report > DLP Archive** or if you subscribed to the FortiCloud service, you can view log archives from there.

The **DLP Archive** menu is only visible if one of the following is true.

- You have configured the FortiGate unit for remote logging and archiving to a FortiAnalyzer unit.
- You have subscribed to FortiCloud.

The following tabs are available when you are viewing DLP archives for one of these protocols.

- **E-mail** to view POP3, IMAP, SMTP, POP3S, IMAPS, SMTPS, and spam email archives.
- **Web** to view HTTP and HTTPS archives.
- **FTP** to view FTP archives.
- **IM** to view AIM, ICQ, MSN, and Yahoo! archives.
- **MMS** to view MMS archives.
- **VoIP** to view session control (SIP, SIMPLE and SCCP) archives.

If you need to view log archives in Raw format, select **Raw** beside the **Column Settings** icon.

## GTP basic concepts

GPRS currently supports data rates from 9.6 kbps to more than 100 kbps, and is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based), and the base station unit sends the message to the carrier network and eventually the Internet (wired carrier network).

The network system then either sends the message back to a base station and to the destination mobile unit, or forwards the message to the proper carrier's network where it gets routed to the mobile unit.

## PDP Context

The packet data protocol (PDP) context is a connection between a mobile station and the end address that goes through the SGSN and GGSN. It includes identifying information about the mobile customer used by each server or device to properly forward the call data to the next hop in the carrier network, typically using a GTP tunnel between the SGSN and GGSN.

When a mobile customer has an active voice or data connection open, both the SGSN and GGSN have the PDP context information for that customer and session.

When a mobile phone attempts to communicate with an address on an external packet network, either an IP or X.25 address, the mobile station that phone is connected to opens a PDP context through the SGSN and GGSN to the end address. Before any traffic is sent, the PDP context must first be activated.

The information included in the PDP context includes the customer's IP address, the IMSI number of the mobile handset, and the tunnel endpoint ID for both the SGSN and GGSN. The ID is a unique number, much like a session ID on a TCP/IP firewall. All this information ensures a uniquely identifiable connection is made.

Since one mobile device may have multiple connections open at one time, such as data connections to different Internet services and voice connections to different locations, there may be more than one PDP context with the same IP address making the extra identifying information required.

The endpoint that the mobile phone is connecting to only knows about the GGSN — the rest of the GPRS connection is masked by the GGSN.

Along the PDP context path, communication is accomplished in using three different protocols.

- The connection between the Mobile Station and SGSN uses the SM protocol.
- Between SGSN and GGSN GTP is used.
- Between GGSN and the endpoint either IP or X.25 is used.

FortiOS Carrier is concerned with the SGSN to GGSN part of the PDP context — the part that uses GTP.

For more about PDP context, see Tunnel Management Messages.

### Creating a PDP context

While FortiOS Carrier is concerned mostly with the SGSN to GGSN part of the PDP Context, knowing the steps involved in creating a PDP context helps understand the role each device, protocol, and message type plays.

Both mobile stations and GGSNs can create PDP contexts.

#### A Mobile Station creates a PDP context

1. The Mobile Station (MS) sends a `PDP activation request` message to the SGSN including the MS PDP address, and APN.
2. Optionally, security functions may be performed to authenticate the MS.
3. The SGSN determines the GGSN address by using the APN identifier.
4. The SGSN creates a down link GTP tunnel to send IP packets between the GGSN and SGSN.
5. The GGSN creates an entry in its PDP context table to deliver IP packets between the SGSN and the external packet switching network.
6. The GGSN creates an uplink GTP tunnel to route IP-PDU from SGSN to GGSN.
7. The GGSN then sends back to the SGSN the result of the PDP context creation and if necessary the MS PDP address.

8. The SGSN sends an `Activate PDP context accept` message to the MS by returning negotiated the PDP context information and if necessary the MS PDP address.
9. Now traffic can pass from the MS to the external network endpoint.

### A GGSN creates a PDP context

1. The network receives an IP packet from an external network.
2. The GGSN checks if the PDP Context has already been created.
3. If not, the GGSN sends a `PDU notification request` to the SGSN in order to initiate a PDP context activation.
4. The GGSN retrieves the IP address of the appropriate SGSN address by interrogating the HLR from the IMSI identifier of the MS.
5. The SGSN sends to the MS a request to activate the indicated PDP context.
6. The PDP context activation procedure follows the one initiated by the MS. See [“A Mobile Station creates a PDP context”](#).
7. When the PDP context is activated, the IP packet can be sent from the GGSN to the MS.

### Terminating a PDP context

A PDP context remains open until it is terminated. To terminate the PDP context an MS sends a `Deactivate PDP context` message to the SGSN, which then sends a `Delete PDP Context` message to the GGSN. When the SGSN receives a PDP context deletion acknowledgment from the GGSN, the SGSN confirms to the MS the PDP context deactivation. The PDP can be terminated by the SGSN or GGSN as well with a slight variation of the order of the messages passed.

When the PDP Context is terminated, the tunnel it was using is deleted as well. If this is not completed in a timely manner, it is possible for someone else to start using the tunnel before it is deleted. This hijacking will result in the original customer being over billed for the extra usage. Anti-overbilling helps prevent this. See [Configuring Anti-overbilling in FortiOS Carrier](#).

## GPRS security

The GPRS network has some built-in security in the form of GPRS authentication. However this is minimal, and is not sufficient for carrier network security needs. A GTP firewall, such as FortiOS Carrier, is required to secure the Gi, Gn, and Gp interfaces.

### GPRS authentication

GPRS authentication is handled by the SGSN to prevent unauthorized GPRS calls from reaching the GSM network beyond the SGSN (the base station system, and mobile station). Authentication is accomplished using some of the customer's information with a random number and uses two algorithms to create ciphers that then allow authentication for that customer.

User identity confidentiality ensures that customer information stays between the mobile station and the SGSN — no identifying information goes past the SGSN. Past that point other numbers are used to identify the customer and their connection on the network.

Periodically the SGSN may request identity information from the mobile station to compare to what is on record, using the IMEI number.

Call confidentiality is achieved through the use of a cipher, similar to the GPRS authentication described earlier. The cipher is applied between the mobile station and the SGSN. Essentially a cipher mask is XORd with each outgoing frame, and the receiving side XORs with its own cipher to result in the original frame and data.

## Parts of a GTPv1 network

A sample GTP network consists of the end handset sender, the sender's mobile station, the carrier's network including the SGSN and GGSN, the receiver's mobile station, and the receiver handset.

When a handset moves from one mobile station and SGSN to another, the handset's connection to the Internet using GTP tracks the user's location and information. For example, the handset could move from one cell to another, or between countries.

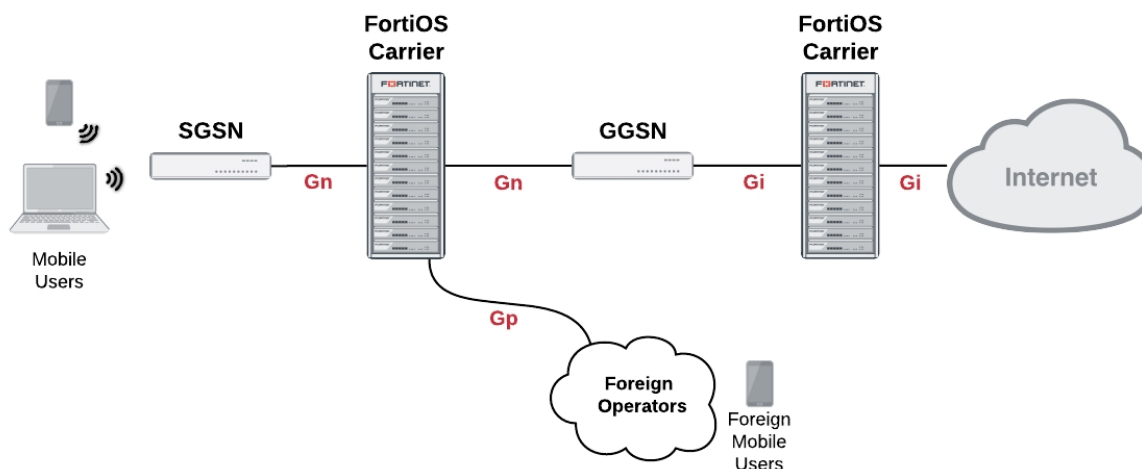

The parts of a GPRS network can be separated into the following groups according to the roles of the devices:

- Radio access to the GPRS network is accomplished by mobile phones and mobile stations (MS).
- Transport the GPRS packets across the GPRS network is accomplished by SGSNs and GGSNs, both local and remote, by delivering packets to the external services.
- Billing and records are handled by CDF, CFR, HLR, and VLR devices.

GPRS networks also rely on access points and PDP contexts as central parts of the communication structure. These are not actual devices, but they are still critical .

These devices, their roles, neighboring devices, the interfaces and protocols they use are outlined in the following table.

### Carrier network showing the interfaces used (GTPv1)

### Devices on a GTPv1 network

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Users	Mobile Stations (MS)	Radio Access Technology (RAT)	

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Stations (MS)	Mobile Users, SGSN	Gb	IP, Frame Relay
SGSN (local)	MS, SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR	Ga, Gb, Gn, Gp, Gz	IP, Frame Relay, GTP, GTP'
SGSN (remote)	SGSN (local)	Gn	GTP
GGSN (local)	SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR	Ga, Gi, Gn, Gp, Gz	IP, GTP, GTP'
GGSN (remote)	SGSN (local), WAP gateway, Internet, other external services	Gi, Gp	IP, GTPv1
CDR, CFR	SGSN (local), GGSN (local)	Ga, Gz	GTP'
HLR, VLR	SGSN (local), GGSN (local)	Ga, Gz	GTP'

## Radio access

For a mobile phone to access the GPRS core network, it must first connect to a mobile station. This is a cellular tower that is connected to the carrier network.

How the mobile phone connects to the mobile station (MS) is determined by what Radio Access Technologies (RATs) are supported by the MS.

## Transport

Transport protocols move data along the carrier network between radio access and the Internet or other carrier networks.

FortiOS Carrier should be present where information enters the Carrier network, to ensure the information entering is correct and not malicious. This means a Carrier-enabled FortiGate unit intercepts the data coming from the SGSN or foreign networks destined for the SSGN or GGSN onto the network, and after the GGSN as the data is leaving the network.

## GTP

GPRS Tunnelling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over a network via tunneling. This tunneling allows users to move between SGSNs and still maintain connection to the Internet through the GGSN.

GTP has three versions version 0, 1, and 2. GTP1 and GTP2 are supported by FortiOS Carrier. The only GTP commands that are common to all forms of GTP are the echo request/response commands that allow GSNs to verify up to once every 60 seconds that neighboring GSNs are alive.

## GTPv0

There have been three versions of GTP to date. The original version of GTP (version 0) has the following differences from version GTPv1.

- the tunnel identification is not random
- there are options for transporting X.25
- the fixed port number 3386 is used for all functions, not just charging
- optionally TCP is allowed as a transport instead of UDP
- not all message types are supported in version 0

## GTPv1

On a GPRS network, Packet Data Protocol (PDP) context is a data structure used by both the Serving GPRS Support Node (SGSN) and the Gateway GPRS Support Node (GGSN). The PDP context contains the subscribers information including their access point, IP address, IMSI number, and their tunnel endpoint ID for each of the SGSN and GGSN.

The Serving GPRS Support Node (SGSN) is responsible for the delivery of data packets from and to the mobile stations within its geographical service area. Its tasks include packet routing and transfer, mobility management (attach/detach and location management), logical link management, and authentication and charging functions. The location register of the SGSN stores location information (e.g., current cell, current VLR) and user profiles (e.g., IMSI, address(es) used in the packet data network) of all GPRS users registered with this SGSN.

## GTPv1-C

GTPv1-C refers to the control layer of the GPRS Transmission network. This part of the protocol deals with network related traffic.

FortiOS Carrier handles GTPv1-C in GTPv1 by using the Tunnel Endpoint Identifier (TEID), IP address and a Network layer Service Access Point Identifier (NSAPI), sometimes called the application identifier, as an integer value that is part of the PDP context header information used to identify a unique PDP context in a mobile station, and SGSN.

For more information on GTPv1-C, see GTP-C messages.

## GTPv1-U

GTPv1-U is defined in 3GPP TS 29.281 and refers to the user layer of the GPRS Tunneling network. This part of the protocol deals with user related traffic, user tunnels, and user administration issues.

A GTPv1-U tunnel is identified by a TEID, an IP address, and a UDP port number. This information uniquely identifies the limb of a GTPv1 PDP context. The IP address and the UDP port number define a UDP/IP path, a connectionless path between two endpoints (i.e. SGSN or GGSN). The TEID identifies the tunnel endpoint in the receiving GTPv1-U protocol entity; it allows for the multiplexing and demultiplexing of GTP tunnels on a UDP/IP path between a given GSN-GSN pair. For more information on GTPv1-U, see GTP-U messages.

The GTP core network consists of one or more SGSNs and GGSNs.

## GGSN

The Gateway GPRS Support Node (GGSN) connects the GPRS network on one side via the SGSN to outside networks such as the Internet. These outside networks are called packet data networks (PDNs). The GGSN acts as an edge router between the two different networks — the GGSN forwards incoming packets from the external PDN to the addressed SGSN and the GGSN also forwards outgoing packets to the external PDN. the GGSN also converts the packets from the GPRS packets with SGSN to the external packets, such as IP or X.25.

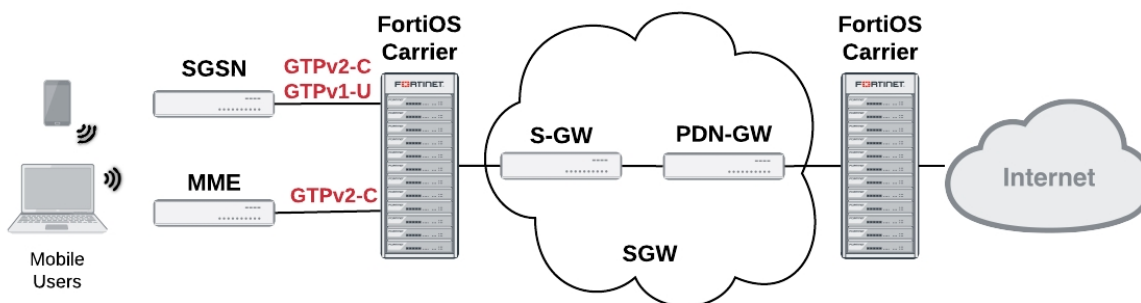

## SGSN

The Serving GPRS Support Node (SGSN) connects the GPRS network to GTPv1 compatible mobile stations, and mobile units (such as UTRAN and ETRAN) on one side and to the gateway node (GGSN), which leads to external networks, on the other side. Each SGSN has a geographical area, and mobile phones in that area connect to the GPRS network through this SGSN. The SGSN also maintains a location register that contains customer's location and user profiles until they connect through a different SGSN at which time the customer information is moved to the new SGSN. This information is used for packet routing and transfer, mobility management also known as location management, logical link management, and authentication and billing functions.

## GTPv2

GTPv2, defined in 3GPP TS 29.274, is dramatically different from GTPv1, defined in 3GPP TS 29.060. Where in GTPv1 the tunnel is between the SGSN and the GGSN, in GTPv2 The SGSN is between the MME and the LTE Serving Gateway (S-GW), beyond which is the PDN gateway (P-GW). Even tunnel management messages have changed significantly.

### Network diagram for GTPv2

### Device roles on a GTPv2 network

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Users	Mobile Stations (MS)	Radio Access Technology (RAT)	--
GTPv1 Mobile Stations (MS)	Mobile Users, SGSN	Gb	IP, Frame Relay

Device role	Neighboring Devices	Interfaces used	Protocols used
GTPv2 Mobile Stations (MS)	Mobile Users, MME	???	IP, Frame Relay
SGSN (local)	GTPv1 MS, SGSN, S-GW	???	IP, Frame Relay, GTPv1, GTP'
S-GW	SGSN, MME, P-GW	???	IP, GTPv2, GTP'
P-GW	S-GW, Internet, other external services	???	IP, GTPv2

### GTPv2-C

GTPv2-C is the control layer messaging for GTPv2. It is used by LTE mobile stations, SGSN units for backwards compatibility, and SGWs that are the gateway to other networks. The messaging is very different from GTPv1. GTPv2-C is required to communicate with the Mobility Management Entity (MME) to create, change and delete EPS bearers when handover events happen, and to create Forwarding tunnels. The protocol is also used to communicate with the Serving Gateway (SGW) which has the S-GW and PDN-GW interfaces, and the Serving GPRS Support Node (SGSN).

### MME

MME essentially fills the role of the SGSN in a GTPv1 network — it is how the mobile stations gain access to the Carrier network. GTPv2 supports different mobile stations than GTPv1, so MME handles the GTPv2 MSes and SGSN handles the GTPv1 MSes

## Billing and records

A major part of the GPRS network is devoted to billing. Customer billing requires enough information to identify the customer, and then billing specific information such as connection locations and times, as well as amount of data transferred. A modified form of GTP called GTP' is used for billing. The home location records and visitor location records store information about customers that is critical to billing.

### GTP' (GTP prime)

GTP is used to handle tunnels of user traffic between SGSNs and GGSNs. However for billing purposes, other devices that are not supported by GTP are required. GTP' (GTP prime) is a modified form of GTP and is used to communicate with these devices such as the Charging Data Function (CDF) that communicates billing information to the Charging Gateway Function (CGF). In most cases, GTP' transports user records from many individual network elements, such as the GGSNs, to a centralism computer which then delivers the charging data more conveniently to the network operator's billing center, often through the CGF. The core network sends charging information to the CGF, typically including PDP context activation times and the quantity of data which the end user has transferred.

GTP' is used by the Ga and Gz interfaces to transfer billing information. GTP' uses registered UDP/TCP port 3386. GTP' defines a different header, additional messages, field values, as well as a synchronization protocol to avoid losing or duplicating CDRs on CGF or SGSN/GGSN failure. Transferred CDRs are encoded in ASN.1.

## HLR

The Home Location Register (HLR) is a central database that contains details of each mobile phone subscriber that is authorized to use the GSM core network. There can be several logical, and physical, HLRs per public land mobile network (PLMN), though one international mobile subscriber identity (IMSI)/MSISDN pair can be associated with only one logical HLR (which can span several physical nodes) at a time. The HLRs store details of every SIM card issued by the mobile phone operator. Each SIM has a unique identifier called an IMSI which is the primary key to each HLR record.

## VLR

The Visitor Location Register (VLR) is a database which stores information about all the mobile devices that are currently under the jurisdiction of the Mobile Switching Center which it serves. Of all the information the VLR stores about each Mobile Station, the most important is the current Location Area Identity (LAI). This information is vital in the call setup process.

Whenever an MSC detects a new MS in its network, in addition to creating a new record in the VLR, it also updates the HLR of the mobile subscriber, informing it of the new location of that MS.

For more information on GTP', see GTP-U and Charging Management Messages.

## GPRS network common interfaces

There are interfaces for each connection on the GPRS network. An interface is an established standard form of communication between two devices. Consider a TCP/IP network. In addition to the transport protocol (TCP) there are other protocols on that network that describe how devices can expect communications to be organized, just like GPRS interfaces.

### Interfaces between devices on the network

There are a series of interfaces that define how different devices on the carrier network communicate with each other. These interfaces are called Ga to Gz, and each one defines how a specific pair of devices will communicate. For example Gb is the interface between the base station and the SGSN, and Gn is one possible interface between the SGSN and GGSN.

The SGSN and GGSN keep track of the CDR information and forward it to the Charging Data Function (CDF) using the Gr interface between the SGSN and home location register (HLR), Gs interface between the SGSN and MSC (VLR), Gx interface between the GGSN and the Charging Rules Function (CRF), Gy between the GGSN and online charging system (OCS), and finally Gz which is the off-line (CDR-based) charging interface between the GSN and the CG that uses GTP'.

Each of these interfaces on the GPRS network has a name in the format of G<sub>x</sub> where x is a letter of the alphabet that determines what part of the network the interface is used in. It is common for network diagrams of GPRS networks to include the interface name on connections between devices.

The Carrier-enabled FortiGate unit only provides protection on the Gn, Gp, and Gi interfaces.

---

**GPRS network interfaces, their roles, and billing**

Name	Device connections that use this interface	Traffic Protocol used	Its role or how it affects billing
<b>Ga</b>	CDR and GSN (SGSNs and GGSNs)	GTP <sup>*</sup> - GTP modified to include CDR role	CDR have the accounting records, that are compiled in the GSN and then sent to the Charging Gateway (CG)
<b>Gb</b>	MS and SGSN	Frame Relay or IP	When an IP address moves to a new MS, the old MS may continue to use and bill that IP address.
<b>Gi</b>	GGSN and public data networks (PDNs)	IP based	This is the connection to the Internet. If the GTP tunnel is deleted without notifying the Gi interface, the connection may remain open incurring additional charges. FortiOS Carrier adds this interface to a firewall. See Anti-overbilling with FortiOS Carrier.
<b>Gn</b>	SGSN and external SGSNs and internal GGSNs	GTP	When the GTP tunnel is deleted, need to inform other interfaces immediately to prevent misuse of connections remaining open. FortiOS Carrier adds this interface to a firewall.
<b>Gp</b>	Internal SGSN and external GGSNs	GTP	
<b>Gz</b>	GSN (SGSN and GGSN) and the charging gateway (CG)	GTP <sup>*</sup>	Used for the offline charging interface. Ga is used for online charging.

Corporate customers may have a direct connection to the Gi interface for higher security. The Gi interface is normally an IP network, though a tunnelling protocol such as GRE or IPsec may be used instead.

## GTP Configuration

The GTP (GPRS Tunneling Protocol) is one of the major mobile core protocols used since to transfer data in the core mobile network. Mobility and data are exploding and this trend will continue with VoLTE, 5G, and the Internet of Things (IoT). The role of GTP in mobile networks will continue to remain critical.

With the mobile network ever growing importance as the communication channel for data rich application on mobile devices, connected intelligent devices and the IoT, comes the growing potential for attacks on the mobile infrastructure.

## Introduction to GTP

### GTP as a Potential Attack Vector

GTP's role in transferring data in the core mobile infrastructure makes it a potential ideal attack vector. To understand the security features for GTP we need to understand the risks that might compromise this protocol.

The business impact might vary in-between the different attacks from Denial of Service (DoS) attacks that hinders the capability of performing a legitimate operation due to resource starvation (for example - not being able to charge the customer for GPRS traffic use due to denial of service attack on the Charging GW) to remote compromise attacks that allows the hacker to have remote control of a critical device (for example – take control over a GGSN).

GTP-based attacks may have a wide range of business impact, based on the attacked devices' vulnerability, ranging from service unavailability, compromise customer information, and gaining control over infrastructure elements, just to give a few examples.

Listed below are the main categories of GTP-based attacks:

- **Protocol anomaly attacks** are packets and packets formats that should not be expected on the GTP protocol. These can include malformed packets, reserved packets' fields and types, etc.
- **Infrastructure attacks** are attempts to connect to restricted core elements, such as the GGSN, SGSN, PGW, etc.
- **Overbilling attacks** results in customers charged for traffic they did not use or the opposite of not paying for the used traffic.

### Protecting Against GTP-Based Attacks: The Carrier Grade GTP Firewall

With the evolution of the mobile network so has GTP evolved. The awareness to the potential of GTP-based attacks has led mobile core vendors to harden their software to better deal with a potential attack. Alongside this evolution, network security vendors, such as Fortinet, has led the way in providing specific GTP aware firewalls to secure and protect the different versions of the GTP protocol from potential attacks.

A GTP firewall should be placed where GTP traffic and session originate and terminate, as shown in the below diagram, and has to inspect both the GTP-C (Control Plane) and GTP-U (Data Plane) packets that, together, constitute the GPRS Tunneling Protocol.

The GTP firewall in both cases is placed in line between the SGSN / SGW and the GGSN / PGW which are the initiator and terminator of the GTP traffic. One of the main roles of GTP firewall is also to be able to support the roaming between different versions of GTP without interrupting the service.

The GTP firewall must be carrier grade in its ability to scale and provide high availability without impact its ability to provide effective protection.

### FortiGate with FortiCarrier – The Leading GTP Firewall

FortiGate is Fortinet's physical security platform, built specifically for high performance and scalability with the utilization of specialized FortiASIC technology. Fortinet Content Processors (CP) and Network Processors (NP) enable, offloading CPU intensive tasks and allowing the FortiGate to provide carrier grade performance and scalability. Utilizing the power of the FortiGate platform, FortiOS, Fortinet's security Operating System, provides threat intelligence and advanced functionalities to provide effective security, ranging from Carrier Grade NAT (CGNAT), firewalling, IPSec, etc.

FortiCarrier is the part of FortiOS which was specifically designed to provide security for specific carriers and mobile operators' protocols and requirements, such as awareness and security for GTP. The wide range of FortiGate platforms with FortiOS and FortiCarrier enables mobile operators to cost effectively secure their mobile network against GTP-based attacks, while ensuring unparalleled performance, availability and security effectiveness.

## GTP Profile

You can configure multiple GTP profiles within the GTP menu. GTP profiles concern GTP activity flowing through the unit. These GTP profiles are then applied to a security policy.

### GTP profile configuration settings

The following are GTP profile configuration settings in **Security Profiles > GTP Profiles**.

GTP Profile	
Lists each GTP profile that you have created. On this page, you can edit, delete or create a new GTP profile.	
<b>Create New</b>	Creates a new GTP profile. When you select <b>Create New</b> , you are automatically redirected to the New page.
<b>Edit</b>	Modifies settings within a GTP profile in the list. When you select <b>Edit</b> , you are automatically redirected to Edit page.
<b>Delete</b>	Removes a GTP profile from the list.
	To remove multiple GTP profiles from within the list, on the GTP Profile page, in each of the rows of the profiles you want removed, select the check box and then select <b>Delete</b> .
<b>Delete</b>	To remove all GTP profiles from within the list, on the GTP Profile page, select the check box in the check box column and then select <b>Delete</b> .
<b>Name</b>	The name of the GTP profile.

Displays the number of times the object is referenced to other objects. For example, av\_1 profile is applied to a security policy; on the Profile page (**Security Profiles > Antivirus > Profiles**), 1 appears in **Ref.** .

To view the location of the referenced object, select the number in **Ref.**, and the Object Usage window appears displaying the various locations of the referenced object.

To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window:

**Ref.**

- **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at.
- **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av\_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page.
- **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av\_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

### New GTP Profile

Provides settings for configuring a GTP profile.

<b>Name</b>	Enter a name for the GTP profile.
<b>General Settings</b>	Configure general options for the GTP profile.
<b>Message Type Filtering</b>	Configure filtering for messages.
<b>APN Filtering</b>	Configure filtering options for APN.
<b>Basic Filtering</b>	Configure filtering options for IMSI.
<b>Advanced Filtering</b>	Configure advanced filtering options.
<b>IE removal policy</b>	Configure IE removal policy options.
<b>Encapsulated IP Traffic Filtering</b>	Configure filtering options for encapsulated IP traffic.
<b>Encapsulated Non-IP End User Address Filtering</b>	Configure filtering options for encapsulated non-IP end user addresses.
<b>Protocol Anomaly</b>	Configure protocol anomaly options.

<b>Anti-Overbilling</b>	Configure anti-overbilling options.
-------------------------	-------------------------------------

<b>Log</b>	Configure log options.
------------	------------------------

### General settings options

The following are mostly house keeping options that appear in the General Settings area of the GTP configuration page.

#### General Settings section of the New GTP Profile

<b>GTP-in-GTP</b>	<p>Select <b>Allow</b> to enable GTP packets to be allowed to contain GTP packets, or a GTP tunnel inside another GTP tunnel.</p> <p>To block all GTP-in-GTP packets, select <b>Deny</b>.</p>
<b>Minimum Message Length</b>	<p>Enter the shortest possible message length in bytes. Normally this is controlled by the protocol, and will vary for different message types. If a packet is smaller than this limit, it is discarded as it is likely malformed and a potential security risk.</p> <p>The default minimum message length is 0 bytes.</p>
<b>Maximum Message Length</b>	<p>Enter the maximum allowed length of a GTP packet in bytes.</p> <p>A GTP packet contains three headers and corresponding parts GTP, UDP, and IP. If a packet is larger than the maximum transmission unit (MTU) size, it is fragmented to be delivered in multiple packets. This is inefficient, resource intensive, and may cause problems with some applications.</p> <p>By default the maximum message length is 1452 bytes.</p>
<b>Tunnel Limit</b>	<p>Enter the maximum number of tunnels allowed open at one time. For additional GTP tunnels to be opened, existing tunnels must first be closed.</p> <p>This feature can help prevent a form of denial of service attack on your network. This attack involves opening more tunnels than the network can handle and consuming all the network resources doing so. By limiting the number of tunnels at any one time, this form of attack will be avoided.</p> <p>The tunnel limiting applies to the Handover Group, and Authorized SGSNs and GGSNs.</p>

### General Settings section of the New GTP Profile

<b>Tunnel Timeout</b>	<p>Enter the maximum number of seconds that a GTP tunnel is allowed to remain active. After the timeout the unit deletes GTP tunnels that have stopped processing data. A GTP tunnel may hang for various reasons. For example, during the GTP tunnel tear-down stage, the "delete pdap context response" message may get lost. By setting a timeout value, you can configure the FortiOS Carrier firewall to remove the hanging tunnels.</p> <p>The default is 86400 seconds, or 24 hours.</p>
<b>Control plane message rate limit</b>	<p>Enter the number of packets per second to limit the traffic rate to protect the GSNs from possible Denial of Service (DoS) attacks. The default limit of <b>0</b> does not limit the message rate.</p> <p>GTP DoS attacks can include:</p> <ul style="list-style-type: none"> <li>• <b>Border gateway bandwidth saturation:</b> A malicious operator can connect to your GRX and generate high traffic towards your Border Gateway to consume all the bandwidth.</li> <li>• <b>GTP flood:</b> A GSN can be flooded by illegitimate traffic</li> </ul>
<b>Handover Group</b>	<p>Select the allowed list of IP addresses allowed to take over a GTP session when the mobile device moves locations.</p> <p>Handover is a fundamental feature of GPRS/UMTS, which enables subscribers to seamlessly move from one area of coverage to another with no interruption of active sessions. Session hijacking can come from the SGSN or the GGSN, where a fraudulent GSN can intercept another GSN and redirect traffic to it. This can be exploited to hijack GTP tunnels or cause a denial of service.</p> <p>When the handover group is defined it acts like a white list with an implicit default deny at the end — the GTP address must be in the group or the GTP message will be blocked. This stops handover requests from untrusted GSNs.</p>
<b>Authorized SGSNs</b>	<p>Use <b>Authorized SGSNs</b> to only allow authorized SGSNs to send packets through the unit and to block unauthorized SGSNs. Go to <b>Firewall Objects &gt; Address &gt; Addresses</b> and add the IP addresses of the authorized SGSNs to a firewall address or address group. Then set <b>Authorized SGSNs</b> to this firewall address or address group.</p> <p>You can use <b>Authorized SGSNs</b> to allow packets from SGSNs that have a roaming agreement with your organization.</p>

### General Settings section of the New GTP Profile

#### Authorized GGSNs

Use **Authorized GGSNs** to only allow authorized GGSNs to send packets through the unit and to block unauthorized GGSNs. Go to **Firewall Objects > Address > Addresses** and add the IP addresses of the authorized GGSNs to a firewall address or address group. Then set **Authorized GGSNs** to this firewall address or address group.

You can use Authorized GGSNs to allow packets from SGSNs that have a roaming agreement with your organization.

### Message type filtering options

On the **New GTP Profile** page, you can select to allow or deny the different types of GTP messages, which is referred to as message type filtering. You must expand the Message Type Filtering section to access the settings.

The messages types include Path Management, Tunnel Management, Location Management, Mobility Management, MBMS, and GTP-U and Charging Management messages.

For enhanced security, Fortinet best practices dictate that you set Unknown Message Action to deny. This will block all unknown GTP message types, some of which may be malicious.

To configure message type filter options, expand **Message Type Filtering** in the GTP profile.

### APN filtering options

An Access Point Name (APN) is an Information Element (IE) included in the header of a GTP packet. It provides information on how to reach a network.

An APN has the following format:

```
<network_id>[.mnc<mnc_int>.mcc<mcc_int>.gprs]
```

Where:

- `<network_id>` is a network identifier or name that identifies the name of a network, for example, `example.com` or `internet`.
- `[.mnc<mnc_int>.mcc<mcc_int>.gprs]` is the optional operator identifier that uniquely identifies the operator's PLMN, for example `mnc123.mcc456.gprs`.

Combining these two examples results in a complete APN of `internet.mnc123.mcc456.gprs`.

By default, the unit permits all APNs. However, you can configure APN filtering to restrict roaming subscribers' access to external networks.

APN filtering applies only to the GTP **create pdp request** messages. The unit inspects GTP packets for both APN and selected modes. If both parameters match and APN filter entry, the unit applies the filter to the traffic.

Additionally, the unit can filter GTP packets based on the combination of an IMSI prefix and an APN.

You cannot add an APN when creating a new profile.

APN Filtering	
<b>Enable APN Filter</b>	Select to enable APN filtering.
<b>Default APN Action</b>	Select the default action for APN filtering. If you select <b>Allow</b> , all sessions are allowed except those blocked by individual APN filters. If you select <b>Deny</b> , all sessions are blocked except those allowed by individual APN filters.
<b>Value</b>	The APN to be filtered.
<b>Mode</b>	The type of mode chosen that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription:
<b>Action</b>	The type of action that will be taken.
<b>Edit</b>	Modifies the settings within the filter. When you select <b>Edit</b> , the Edit window appears, which allows you to modify the settings of the APN.
<b>Delete</b>	Removes the APN from the list within the table, in the APN Filtering section.
<b>Add APN</b>	Adds a new APN filter to the list. When you select <b>Add APN</b> , the New window appears, which allows you to configure the APN settings.
New APN page	
<b>Value</b>	Enter an APN to be filtered. You can include wild cards to match multiple APNs. For example, the value <b>internet*</b> would match all APNs that begin with <b>internet</b> .
<b>Mode</b>	Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
<b>Mobile Station provided</b>	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
<b>Network provided</b>	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
<b>Subscription Verified</b>	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network.
<b>Action</b>	Select <b>Allow</b> or <b>Deny</b> .

## Basic filtering options

The International Mobile Station Identity (IMSI) is used by a GPRS Support Node (GSN) to identify a mobile station. Three elements make up every IMSI:

- the mobile country code (MCC)
- the mobile network code (MNC)
- the mobile subscriber identification number (MSIN).

The subscriber's home network—the public land mobile network (PLMN)—is identified by the IMSI prefix, formed by combining the MCC and MNC.

By default, the unit allows all IMSIs. You can add IMSI prefixes to deny GTP traffic coming from non-roaming partners. Any GTP packets with IMSI prefixes not matching the prefixes you set will be dropped. GTP **Create pdp** request messages are filtered and only IMSI prefixes matching the ones you set are permitted. Each GTP profile can have up to 1000 IMSI prefixes set.

An IMSI prefix and an APN can be used together to filter GTP packets if you set an IMSI filter entry with a non-empty APN.

You cannot add an IMSI when creating a new profile. You must add it after the profile has been created and you are editing the profile.

### IMSI Filtering section of the New GTP Profile

<b>Enable IMSI Filter</b>	Select to enable IMSI filtering.
<b>Default IMSI Action</b>	Select the default action for IMSI filtering. If you select <b>Allow</b> , all sessions are allowed except those blocked by individual IMSI filters. If you select <b>Deny</b> , all sessions are blocked except those allowed by individual IMSI filters.
<b>APN</b>	The APN that is part of the IMSI that will be filtered.
<b>MCC-MNC</b>	The MCC-MNC part of the IMSI that will be filtered.
<b>Mode</b>	The type of mode that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
<b>Action</b>	The type of action that will be taken.
<b>Edit</b>	Modifies settings to an IMSI filter. When you select <b>Edit</b> , the Edit window appears, which allows you to modify the IMSI filter's settings.
<b>Delete</b>	Removes an IMSI filter from within the table, in the IMSI Filtering section.
<b>Add IMSI</b>	Adds a new IMSI filter to the list. When you select <b>Add IMSI</b> , the New window appears, which allows you to configure IMSI filter settings.
<b>New IMSI page</b>	

<b>APN</b>	Enter the APN part of the IMSI to be filtered.
<b>MCC-MNC</b>	Enter the MCC-MCC part of the IMSI to be filtered.
<b>Mode</b>	Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
<b>Mobile Station provided</b>	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
<b>Network provided</b>	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
<b>Subscription Verified</b>	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network.
<b>Action</b>	Select <b>Allow</b> or <b>Deny</b> .

### Advanced filtering options

The FortiOS Carrier firewall supports advanced filtering against the attributes RAT, RAI, ULI, APN restriction, and IMEI-SV in GTP to block specific harmful GPRS traffic and GPRS roaming traffic. The following table shows some of the GTP context requests and responses that the firewall supports.

#### Attributes supported by FortiCarrier firewalls

	GTP Create PDP Context Request	GTP Create PDP Context Response	GTP Update PDP Context Request	GTP Update PDP Context Response
<b>APN</b>	yes	yes	-	
<b>APN Restriction</b>	yes	-	-	yes
<b>IMEI-SV</b>	yes	-	-	-
<b>IMSI</b>	yes	-	yes	-
<b>RAI</b>	yes	-	yes	-
<b>RAT</b>	yes	-	yes	-
<b>ULI</b>	yes	-	yes	-

When editing a GTP profile, select **Advanced Filtering > Create New** to create and add a rule. When the rule matches traffic it will either allow or deny that traffic as selected in the rule.

Advanced Filtering	
<b>Enable</b>	Select to enable advanced filtering.
<b>Default Action</b>	Select the default action for advanced filtering. If you select <b>Allow</b> , all sessions are allowed except those blocked by individual advanced filters. If you select <b>Deny</b> , all sessions are blocked except those allowed by individual advanced filters.
<b>Messages</b>	The messages, for example, Create PDP Context Request.
<b>APN Restriction</b>	The APN restriction.
<b>RAT Type</b>	The RAT types associated with that filter.
<b>ULI</b>	The ULI pattern.
<b>RAI</b>	The RAI pattern.
<b>IMEI</b>	The IMEI pattern.
<b>Action</b>	The action that will be taken.
<b>Edit</b>	Modifies the filter's settings. When you select <b>Edit</b> , the Edit window appears, which allows you to modify the filter's settings.
<b>Delete</b>	Removes a filter from the list.
<b>Add</b>	Adds a filter to the list. When you select <b>Add</b> , the New window appears, which allows you to configure settings for messages, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI patterns as well as the type of action.
New Filtering page	
<b>Messages</b>	The PDP content messages this profile will match.
<b>Create PDP Context Request</b>	Select to allow create PDP context requests.
<b>Create PDP Context Response</b>	Select to allow create PDP context responses.
<b>Update PDP Context Request</b>	Select to allow update PDP context requests.

<b>Update PDP Context Response</b>	Select to allow update PDP context responses.
<b>APN</b>	Enter the APN.
<b>APN Mode</b>	<p>Select an APN mode as one or more of</p> <ul style="list-style-type: none"> <li>• Mobile Station provided</li> <li>• Network provided</li> <li>• Subscription provided</li> </ul> <p>This field is only available when an APN has been entered.</p>
<b>Mobile Station provided</b>	MS-provided PAN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
<b>Network provided</b>	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
<b>Subscription verified</b>	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network.
<b>APN Restriction</b>	<p>Select the type of restriction that you want. You can choose all of the types, or one of the types. You cannot choose multiple types. Types include:</p> <ul style="list-style-type: none"> <li>• all</li> <li>• Public-1</li> <li>• Public-2</li> <li>• Private-1</li> <li>• Private-2</li> </ul>
<b>IMSI</b>	Enter the IMSI.
<b>MSISDN</b>	Enter the MSISDN.
<b>RAT Type</b>	<p>Optionally select the RAT type as any combination of the following:</p> <ul style="list-style-type: none"> <li>• Any</li> <li>• UTRAN</li> <li>• GERAN</li> <li>• Wifi</li> <li>• GAN</li> <li>• HSPA</li> </ul> <p>Some RAT types are GTPv1 specific.</p>

<b>ULI pattern</b>	Enter the ULI pattern.
<b>RAI pattern</b>	Enter the RAI pattern.
<b>IMEI pattern</b>	Enter the IMEI pattern.
<b>Action</b>	Select either <b>Allow</b> or <b>Deny</b> .

### Adding an advanced filtering rule

When adding a rule, use the following formats:

- Prefix, for example, range 31\* for MCC matches MCC from 310 to 319.
- Range, for example, range 310-319 for MCC matches MCC from 310 to 319.
- Mobile Country Code (MCC) consists of three digits. The MCC identifies the country of domicile of the mobile subscriber.
- Mobile Network Code (MNC) consists of two or three digits for GSM/UMTS applications. The MNC identifies the home PLMN of the mobile subscriber. The length of the MNC (two or three digits) depends on the value of the MCC. Best practices dictate not to mix two and three digit MNC codes within a single MCC area.
- Location Area Code (LAC) is a fixed length code (of 2 octets) identifying a location area within a PLMN. This part of the location area identification can be coded using a full hexadecimal representation except for the following reserved hexadecimal values: 0000 and FFFE. These reserved values are used in some special cases when no valid LAI exists in the MS (see 3GPP TS 24.008, 3GPP TS 31.102 and 3GPP TS 51.011).
- Routing Area Code (RAC) of a fixed length code (of 1 octet) identifies a routing area within a location.
- CI or SAC of a fixed length of 2 octets can be coded using a full hexadecimal expression.
- Type Allocation Code (TAC) has a length of 8 digits.
- Serial Number (SNR) is an individual serial number identifying each equipment within each TAC. SNR has a length of 6 digits.
- Software Version Number (SVN) identifies the software version number of the mobile equipment. SVN has a length of 2 digits.

You cannot add an advanced filtering rule when creating a new profile. You must add it after the profile has been created and you are editing the profile.

### Information Element (IE) removal policy options

In some roaming scenarios, the unit is installed on the border of the PLMN and the GRX. In this configuration, the unit supports information element (IE) removal policies to remove any combination of R6 IEs (RAT, RAI, ULI, IMEI-SV and APN restrictions) from the types of messages described in “[Advanced filtering options](#)”, prior to forwarding the messages to the HGGSN (proxy mode).

<b>IE removal policy</b>	
<b>Enable</b>	Select to enable this option.

<b>SGSN address of message IE</b>	The firewall address or address group that contains the SGSN addresses.
<b>IEs to be removed</b>	The IE types that will be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.
<b>Add</b>	Adds an IE removal policy. When you select <b>Add</b> , the New window appears, which allows you to configure the IE policy.
<b>Edit</b>	Modifies settings from within the IE removal policy. When you select <b>Edit</b> , the Edit window appears, which allows you to modify the settings within the policy.
<b>Delete</b>	Removes the IE removal policy from the list.
<b>New IE policy page</b>	
<b>SGSN address</b>	Select a firewall address or address group that contains SGSN addresses.
<b>IEs to be removed</b>	Select one or more IE types to be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.

### Encapsulated IP traffic filtering options

You can use encapsulated IP traffic filtering to filter GTP sessions based on information contained in the data stream. to control data flows within your infrastructure. You can configure IP filtering rules to filter encapsulated IP traffic from mobile stations by identifying the source and destination policies. For more information, see When to use encapsulated IP traffic filtering.

Expand **Encapsulated IP Traffic Filtering** in the GTP profile to reveal the options.

<b>Encapsulated IP Traffic Filtering</b>	
<b>Enable IP Filter</b>	Select to enable encapsulated IP traffic filtering options.
<b>Default IP Action</b>	Select the default action for encapsulated IP traffic filtering. If you select <b>Allow</b> , all sessions are allowed except those blocked by individual encapsulated IP traffic filters. If you select <b>Deny</b> , all sessions are blocked except those allowed by individual encapsulated IP traffic filters.
<b>Source</b>	Select a source IP address from the configured firewall IP address or address group lists. Any encapsulated traffic originating from this IP address will be a match if the destination also matches.
<b>Destination</b>	Select a destination IP address from the configured firewall IP address or address group lists. Any encapsulated traffic being sent to this IP address will be a match if the destination also matches.

<b>Action</b>	The type of action that will be taken.  Select to <b>Allow</b> or <b>Deny</b> encapsulated traffic between this source and Destination.
<b>Edit</b>	Modifies the source, destination or action settings.
<b>Add IP Policy</b>	Adds a new encapsulated IP traffic filter. When you select <b>Add IP Policy</b> , the New window appears which allows you to configure IP policy settings.
<b>New (window)</b>	
<b>Source</b>	Select the source firewall address or address group.
<b>Destination</b>	Select the destination firewall address or address group.
<b>Action</b>	Select <b>Allow</b> or <b>Deny</b> .

### Encapsulated non-IP end user traffic filtering options

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications list only PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the "Assigned PPP DLL Protocol Numbers" sections of RFC1700. The PDP types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

Encapsulated Non-IP End User Address Filtering	
<b>Enable Non-IP Filter</b>	Select to enable encapsulated non-IP traffic filtering.
<b>Default Non-IP Action</b>	Select the default action for encapsulated non-IP traffic filtering. If you select <b>Allow</b> , all sessions are allowed except those blocked by individual encapsulated non-IP traffic filters. If you select <b>Deny</b> , all sessions are blocked except those allowed by individual encapsulated non-IP traffic filters.
<b>Type</b>	The type chosen, <b>AESTI</b> or <b>IETF</b> .
<b>Start Protocol</b>	The beginning protocol port number range.
<b>End Protocol</b>	The end of the protocol port number range.
<b>Action</b>	The type of action that will be taken.

<b>Edit</b>	Modify a non-IP filter's settings in the list. When you select <b>Edit</b> , the Edit window appears, which allows you to modify the Non-IP policy settings.
<b>Delete</b>	Remove a non-IP policy from the list.
<b>Add Non-IP Policy</b>	Add a new encapsulated non-IP traffic filter. When you select <b>Add Non-IP Policy</b> , you are automatically redirected to the New page.
<b>New (window)</b>	
<b>Type</b>	Select <b>AESTI</b> or <b>IETF</b> .
<b>Start Protocol</b> <b>End Protocol</b>	Select a start and end protocol from the list of protocols in RFC 1700. Allowed range includes 0 to 255 (0x00 to 0xff). Some common protocols include: <ul style="list-style-type: none"> <li>• 33 (0x0021) Internet Protocol</li> <li>• 35 (0x0023) OSI Network Layer</li> <li>• 63 (0x003f) NETBIOS Framing</li> <li>• 65 (0x0041) Cisco Systems</li> <li>• 79 (0x004f) IP6 Header Compression</li> <li>• 83 (0x0053) Encryption</li> </ul>
<b>Action</b>	Select <b>Allow</b> or <b>Deny</b> .

### Protocol Anomaly prevention options

Use protocol anomaly detection options to detect or deny protocol anomalies according to GTP standards and tunnel state. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of the protocol specifications. Packets cannot pass through if they fail the sanity check.

Protocol Anomaly	
<b>Invalid Reserved Field</b>	GTP version 0 (GSM 09.60) headers specify a number of fields that are marked as "Spare" and contain all ones (1). GTP packets that have different values in these fields are flagged as anomalies. GTP version 1 (GSM 29.060) makes better use of the header space and only has one, 1-bit, reserved field. In the first octet of the GTP version1 header, bit 4 is set to zero.
<b>Reserved IE</b>	Both versions of GTP allow up to 255 different Information Elements (IE). However, a number of Information Elements values are undefined or reserved. Packets with reserved or undefined values will be filtered.
<b>Miss Mandatory IE</b>	GTP packets with missing mandatory Information Elements (IE) will not be passed to the GGSN.

<b>Out of State Message</b>	<p>The GTP protocol requires a certain level of state to be kept by both the GGSN and SGSN. Some message types can only be sent when in a specific GTP state. Packets that do not make sense in the current state are filtered or rejected</p> <p>Both versions of GTP allow up to 255 different message types. However, a number of message type values are undefined or reserved.</p> <p>Best practices dictate that packets with reserved or undefined values will be filtered.</p>
<b>Out of State IE</b>	GTP Packets with out of order Information Elements are discarded.
<b>Spoofed Source Address</b>	<p>The End User Address Information Element in the PDP Context Create &amp; Response messages contain the address that the mobile station (MS) will use on the remote network. If the MS does not have an address, the SGSN will set the End User Address field to zero when sending the initial PDP Context Create message. The PDP Context Response packet from the GGSN will then contain an address to be assigned to the MS. In environments where static addresses are allowed, the MS will relay its address to the SGSN, which will include the address in the PDP Context Create Message. As the MS address is negotiated within the PDP Context creation handshake, any packets originating from the MS that contain a different source address are detected and dropped.</p>

## Anti-Overbilling options

You can configure the FortiOS Carrier firewall to prevent over billing subscribers for traffic over the. To enable anti-overbilling, you must configure both the Gn/Gp firewall and the Gi firewall.

Expand **Anti-Overbilling** in the GTP profile to reveal these settings.

<b>Anti-Overbilling</b>	
<b>Gi Firewall IP Address</b>	The IP address of the unit's interface configured as a Gi gateway.
<b>Port</b>	The SG security port number. The default port number is port 21123. Change this number if your system uses a different SG port.
<b>Interface</b>	Select the unit interface configured as a Gi gateway.
<b>Security Context ID</b>	Enter the security context ID. This ID must match the ID entered on the server Gi firewall. The default security context ID is 696.

## Log options

All the GTP logs are treated as a subtype of the event logs. To enable GTP logging, you must:

- configure the GTP log settings in a GTP profile

<b>Log</b>	
<b>Log Frequency</b>	<p>Enter the number of messages to drop between logged messages.</p> <p>An overflow of log messages can sometimes occur when logging rate-limited GTP packets exceed their defined threshold. To conserve resources on the syslog server and the Carrier-enabled FortiGate unit, you can specify that some log messages are dropped. For example, if you want only every twentieth message to be logged, set a logging frequency of 20. This way, 20 messages are skipped and the next logged.</p> <p>Acceptable frequency values range from 0 to 2147483674. When set to '0', no messages are skipped.</p>
<b>Forwarded Log</b>	Select to log forwarded GTP packets.
<b>Denied Log</b>	Select to log GTP packets denied or blocked by this GTP profile.
<b>Rate Limited Log</b>	Select to log rate-limited GTP packets.
<b>State Invalid Log</b>	Select to log GTP packets that have failed stateful inspection.
<b>Tunnel Limit Log</b>	Select to log packets dropped because the maximum limit of GTP tunnels for the destination GSN is reached.
<b>Extension Log</b>	<p>Select to log extended information about GTP packets. When enabled, this additional information will be included in log entries:</p> <ul style="list-style-type: none"> <li>• IMSI</li> <li>• MSISDN</li> <li>• APN</li> <li>• Selection Mode</li> <li>• SGSN address for signaling</li> <li>• SGSN address for user data</li> <li>• GGSN address for signaling</li> <li>• GGSN address for user data</li> </ul>

**Traffic count Log**

Select to log the total number of control and user data messages received from and forwarded to the GGSNs and SGSNs that the unit protects.

The unit can report the total number of user data and control messages received from and forwarded to the GGSNs and SGSNs it protects. Alternately, the total size of the user data and control messages can be reported in bytes. The unit differentiates between traffic carried by each GTP tunnel, and also between GTP-User and GTP-Control messages.

The number of messages or the number of bytes of data received from and forwarded to the SGSN or GGSN are totaled and logged if a tunnel is deleted.

When a tunnel is deleted, the log entry contains:

- Timestamp
- Interface name (if applicable)
- SGSN IP address
- GGSN IP address
- TID
- Tunnel duration time in seconds
- Number of messages sent to the SGSN
- Number of messages sent to the GGSN

## Specifying logging types

You can configure the unit to log GTP packets based on their status with GTP traffic logging.

The status of a GTP packet can be any of the following 5 states:

- **Forwarded** - a packet that the unit transmits because the GTP policy allows it
- **Prohibited** - a packet that the unit drops because the GTP policy denies it
- **Rate-limited** - a packet that the unit drops because it exceeds the maximum rate limit of the destination GSN
- **State-invalid** - a packet that the unit drops because it failed stateful inspection
- **Tunnel-limited** - a packet that the unit drops because the maximum limit of GTP tunnels for the destination GSN is reached.

The following information is contained in each log entry:

- Timestamp
- Source IP address
- Destination IP address
- Tunnel Identifier (TID) or Tunnel Endpoint Identifier (TEID)
- Message type
- Packet status: forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited
- Virtual domain ID or name
- Reason to be denied if applicable.

## GTP performance

There are independent Receive and Transmit queues for `gtp-u` process. These queues are and their associated resources are initialized when the `ftp-enhance-mode` is enabled.

### CLI changes under system npu

#### gtp-enhance-mode

```
config system npu
  set gtp-enhance-mode [enable|disable]
end
```

This configuration requires a reboot of the device to initialize the changes.

#### gtp-enhance-cpu-range

This is used to set the CPUs which can process the GTP-U packet inspection.

```
config system npu
  set gtp-enhance-cpu-range [0|1|2]
end
```

Option	Description
0	Inspect GTPU packets by all CPUs
1	Inspect GTPU packets by Master CPUs
2	Inspect GTPU packets by Slave CPUs

### Diagnose commands

```
diagnose npu np6 hbq-stats [all|np xx]
```

Used to see the GTP-U packet counter by all NP or the corresponding np.

```
diagnose npu np6 hbq-stats-clear all /np xx
```

Used to clear the GTP-U packet counter by all NP or the corresponding np.

### Verifying the enhance-mode is disabled

Before execute the test or enable/disable the gtp enhance, first check the `gtp-enhance-mode` status as in the example below:

```
config system npu
  get
  gtp-enhance-mode: disable
  gtp-enhance-cpu-range: 0
end
```

If the `gtp-enhance-mode` is `disable`, use the command `diagnose npu np6 hbq-stats all`.

The output will be similar to below:

```
# diagnose npu np6 hbq-stats all
Total :0
```

If the `gtp-enhance-mode` is enable, use the command `diagnose npu np6 hbq-stats all`

The output will be similar to below:

```
# diagnose npu np6 hbq-stats all
cpu_ 0:0
cpu_ 1:0
cpu_ 2:0
cpu_ 3:0
cpu_ 4:0
cpu_ 5:0
cpu_ 6:0
cpu_ 7:0
cpu_ 8:0
cpu_ 9:0
cpu_10:0
cpu_11:0
cpu_12:0
cpu_13:0
cpu_14:0
cpu_15:0
cpu_16:0
cpu_17:0
cpu_18:0
cpu_19:0
cpu_20:0
cpu_21:0
cpu_22:0
cpu_23:0
cpu_24:0
cpu_25:0
cpu_26:0
cpu_27:0
cpu_28:0
cpu_29:0
cpu_30:0
cpu_31:0
cpu_32:0
cpu_33:0
cpu_34:0
cpu_35:0
cpu_36:0
cpu_37:0
cpu_38:0
cpu_39:0
Total :0
```

Sometimes, when loading the new configure file, and the new configure file does not match the old configure file, the `gtp-enhance-mode` status will be confused.

You can see :

```
#config system npu
#get
gtp-enhance-mode: enable
```

but you can also see that

```
diagnose npu np6 hbq-stats all
Total :0
```

This means the `gtp-enhance-mode` is actually set to `disable`.

The inverse is also possible, when you see

```
#config system npu
#get
gtp-enhance-mode: disable
```

but you also see that

```
# diagnose npu np6 hbq-stats all
cpu_ 0:0
...
cpu_39:0
Total :0
```

This means the `gtp-enhance-mode` is actually set to `enable`.

If these combinations occur, just run the command below:

```
config system npu
  set gtp-enhance-mode enable
end
```

or

```
config system npu
  set gtp-enhance-mode disable
end
```

Once this is done, reboot the device to let the 2 statuses match.

## Configuring GTP on FortiOS Carrier

Configuring GTP support on FortiOS Carrier involves configuring a number of areas of features.

### GTP support on the Carrier-enabled FortiGate unit

The FortiCarrier unit needs to have access to all traffic entering and exiting the carrier network for scanning, filtering, and logging purposes. This promotes one of two configurations — hub and spoke, or bookend.

A hub and spoke configuration with the Carrier-enabled FortiGate unit at the hub and the other GPRS devices on the spokes is possible for smaller networks where a lower bandwidth allows you to divide one unit into multiple virtual domains to fill multiple roles on the carrier network. It can be difficult with a single FortiOS Carrier as the hub to ensure all possible entry points to the carrier network are properly protected from potential attacks such as relayed network attacks.

A bookend configuration uses two Carrier-enabled FortiGate units to protect the carrier network between them with high bandwidth traffic. One unit handles traffic from mobile stations, SGSNs, and foreign carriers. The other handles GGSN and data network traffic. Together they ensure the network is secure.

The Carrier-enabled FortiGate unit can access all traffic on the network. It can also verify traffic between devices, and verify that the proper GPRS interface is being used. For example there is no reason for a Gn interface to be used to communicate with a mobile station — the mobile station will not know what to do with the data — so that traffic is blocked.

When you are configuring your Carrier-enabled FortiGate unit's GTP profile, you must first configure the APN. It is critical to GTP communications — no traffic will flow without the APN.

---

The Carrier-enabled FortiGate unit does more than just forward and route GTP packets over the network. It also performs:

- [GTP support on the Carrier-enabled FortiGate unit](#)
- [GTP support on the Carrier-enabled FortiGate unit](#)
- [GTP support on the Carrier-enabled FortiGate unit](#)
- [GTP support on the Carrier-enabled FortiGate unit](#)
- [GTP support on the Carrier-enabled FortiGate unit](#)

## Packet sanity checking

The FortiOS Carrier firewall checks the following items to determine if a packet confirms to the UDP and GTP standards:

- GTP release version number — must be 0, 1, or 2
- Settings of predefined bits
- Protocol type
- UDP packet length

If the packet in question does not confirm to the standards, the FortiOS Carrier firewall drops the packet, so that the malformed or forged traffic will not be processed.

## GTP stateful inspection

Apart from the static inspection (checking the packet header), the FortiOS Carrier firewall performs stateful inspection.

Stateful inspection provides enhanced security by keeping track of communications sessions and packets over a period of time. Both incoming and outgoing packets are examined. Outgoing packets that request specific types of incoming packets are tracked; only those incoming packets constituting a proper response are allowed through the firewall.

The FortiOS Carrier firewall can also index the GTP tunnels to keep track of them.

Using the enhanced Carrier traffic policy, the FortiOS Carrier firewall can block unwanted encapsulated traffic in GTP tunnels, such as infrastructure attacks. Infrastructure attacks involve attempts by an attacker to connect to restricted machines, such as GSN devices, network management systems, or mobile stations. If these attempts to connect are detected, they are to be flagged immediately by the firewall .

## Protocol anomaly detection and prevention

The FortiOS Carrier firewall detects and optionally drops protocol anomalies according to GTP standards and specific tunnel states. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of protocol specifications. These packets are not seen on a production network. Protocol anomaly attacks exploit poor programming practices when decoding packets, and are typically used to maliciously impair system performance or elevate privileges.

FortiOS Carrier also detects IP address spoofing inside GTP data channel.

See [Protocol anomaly detection and prevention](#).

## HA

FortiOS Carrier active-passive HA provides failover protection for the GTP tunnels. This means that an active-passive cluster can provide FortiOS Carrier firewall services even when one of the cluster units encounters a problem that would result in complete loss of connectivity for a stand-alone FortiOS Carrier firewall. This failover protection provides a backup mechanism that can be used to reduce the risk of unexpected downtime, especially for mission-critical environments.

FortiOS HA synchs TCP sessions by default, but UDP sessions are not synchronized by default. However synchronizing a session is only part of the solution if the goal is to continue GTP processing on a synchronized session after a HA switch. For that to be successful we also need to synch the GTP tunnel state. So, once the master completes tunnel setup then the GTP tunnel is synchronized to the slave.

GTP traffic will only flow without interruption on a HA switch if bidirectional GTP policies have been configured: an internal (GTP server) to external (all) UDP port GTP policy, and an external (all) to internal (GTP server) UDP port GTP policy. If either policy is missing then traffic may be interrupted until traffic flows in the opposite direction.

For more information on HA in FortiOS, see the High Availability (HA) Guide or the FortiOS Administration Guide.

## Virtual domain support

FortiOS Carrier is suited to both large and smaller carriers. A single Carrier-enabled FortiGate unit can serve either one large carrier, or several smaller ones through virtual domains. As with any FortiGate unit, Carrier-enabled units have the ability to split their resources into multiple virtual units. This allows smaller carriers to use just the resources that they need without wasting the extra. For more information on HA in FortiOS, see the Virtual Domains (VDOMs) Guide.

## Configuring General Settings on the Carrier-enabled FortiGate unit

To configure the GTP General Settings, go to **Security Profiles > GTP Profile**, and edit a GTP profile. Expand **General Settings** to configure settings. See General settings options.

## GTP Monitor Mode

The `monitor-mode` setting is part of the GTP profile. The setting shows on all GTP profiles and works for all GTP versions.

When this setting is enabled, if a GTP packet is to be dropped due to a GTP deny case such as:

- GTP\_DENY
- GTP\_RATE\_LIMIT
- GTP\_STATE\_INVALID
- GTP\_TUNNEL\_LIMIT

instead of being dropped, it will be forwarded and logged with the original deny log message and a "-monitor" suffix (e.g., state-invalid-monitor).

This setting is found in the CLI.

```
config firewall gtp
  edit profile_name
    ...
    set monitor-mode [disable*|enable]
    ...
  end
```

end

## Configuring Encapsulated Filtering in FortiOS Carrier

Encapsulated traffic on the GPRS network can come in a number of forms as it includes traffic that is “wrapped up” in another protocol. This detail is important for firewalls because it requires “unwrapping” to properly scan the data inside. If encapsulated packets are treated as regular packets, that inside layer will never be scanned and may allow malicious data into your network.

On Carrier-enabled FortiGate units, GTP related encapsulated filtering falls under encapsulated IP traffic filtering, and encapsulated non-IP end user address filtering.

### Configuring Encapsulated IP Traffic Filtering

Generally there are a very limited number of IP addresses that are allowed to encapsulate GPRS traffic. For example GTP tunnels are a valid type of encapsulation when used properly. This is the GTP tunnel which uses the Gp or Gn interfaces between SGSNs and GGSNs. However, a GTP tunnel within a GTP tunnel is not accessible — FortiOS Carrier will either block or forward the traffic, but is not able to open it for inspection.

The ability to filter GTP sessions is based on information contained in the data stream and provides operators with a powerful mechanism to control data flows within their infrastructure. You can also configure IP filtering rules to filter encapsulated IP traffic from Mobile Stations.

To configure the Encapsulated IP Traffic Filtering, go to **Security Profiles > GTP Profile**, and edit a GTP profile. Expand **Encapsulated IP Traffic Filtering** to configure settings. See Encapsulated IP traffic filtering options.

### When to use encapsulated IP traffic filtering

The following are the typical cases that need encapsulated IP traffic filtering:

#### Mobile station IP pools

In a well-designed network, best practices dictate that the mobile station address pool is to be completely separate from the GPRS network infrastructure range of addresses. Encapsulated IP packets originating from a mobile station will not contain source or destination addresses that fall within the address range of GPRS infrastructures. In addition, traffic originating from the users handset will not have destination/source IP addresses that fall within any Network Management System (NMS) or Charging Gateway (CG) networks.

#### Communication between mobile stations

Mobile stations on the same GPRS network are not able to communicate with other mobile stations. Best practices dictate that packets containing both source and destination addresses within the mobile station's range of addresses are to be dropped.

#### Direct mobile device or internet attacks

It may be possible for attackers to wrap attack traffic in GTP protocols and submit the resulting GTP traffic directly to a GPRS network element from their mobile stations or a node on the Internet. It is possible that the receiving SGSN or GGSN would then strip off the GTP header and attempt to route the underlying attack. This underlying attack could have any destination address and would probably have a source address spoofed as if it were valid from that PLMN.

You cannot add an IE removal policy when you are creating a new profile.

### Relayed network attacks

Depending on the destination the attack could be directly routed, such as to another node of the PLMN, or re wrapped in GTP for transmission to any destination on the Internet outside the PLMN depending on the routing table of the GSN enlisted as the unwitting relay.

The relayed attack could have any source or destination addresses and could be any of numerous IP network attacks, such as an attack to hijack a PDP context, or a direct attack against a management interface of a GSN or other device within the PLMN. Best practices dictate that any IP traffic originating on the Internet or from an MS with a destination address within the PLMN is to be filtered.

### Configuring Encapsulated Non-IP End User Address Filtering

Much of the traffic on the GPRS network is in the form of IP traffic. However some parts of the network do not use IP based addressing, so the Carrier-enabled FortiGate unit is unable to perform Encapsulated IP Traffic Filtering.

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications only list PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the "Assigned PPP DLL Protocol Numbers" sections of RFC 1700. The PDP types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

To configure the Encapsulated Non-IP End User Address Filtering, go to **Security Profiles > GTP Profile**, and edit a GTP profile. Expand **Encapsulated Non-IP End User Address Filtering** to configure settings. See Encapsulated non-IP end user traffic filtering options.

### Configuring the Protocol Anomaly feature in FortiOS Carrier

When anomalies do happen, it is possible for the anomaly to interrupt network traffic or consume network resources — if precautions are not taken. Anomalies can be generated by accident or maliciously, but both methods can have the same results — degrading the performance of the carrier network, or worse.

To configure GTP protocol anomalies, go to **Security Profiles > GTP Profile**, and edit a GTP profile. Expand the **Protocol Anomaly** option. See Protocol Anomaly prevention options.

The following are some examples:

- The GTP header specifies the length of the packet excluding the mandatory GTP header. In GTP version 0 (GSM 09.60), the mandatory GTP header size is 20 bytes, whereas GTP version 1 (GSM 29.060) specifies that the minimum length of the GTP header is 8 bytes. The GTP packet is composed of the header, followed by Information Elements typically presented in a Type-Length-Value format. It is possible for an attacker to create a GTP packet with a GTP header field length that is incompatible with the length of the necessary information elements.

- The same concepts are true for GTP version 2 headers even though there are different fields in them.
- It is similarly possible for an attacker to create a packet with an invalid IE length. Invalid lengths may cause protocol stacks to allocate incorrect amounts of memory, and thereby cause crashes or buffer overflows.

By default the FortiOS Carrier firewall detects these problems, as well as other protocol anomalies, and drops the packets. All protocol anomaly options are set to **Deny** by default. However, you can change the policy to allow them.

## Configuring Anti-overbilling in FortiOS Carrier

GPRS over billing attacks can be prevented with a properly configured Carrier-enabled FortiGate unit.

Over billing can occur when a subscriber returns his IP address to the IP pool. Before the billing server closes it, the subscriber's session is still open and vulnerable. If an attacker takes control of the subscriber's IP address, he can send or receive data and the subscriber will be billed for the traffic.

Over billing can also occur when an available IP address is reassigned to a new mobile station (MS). Subsequent traffic by the previous MS may be forwarded to the new MS. The new MS would then be billed for traffic it did not initiate.

### Anti-overbilling with FortiOS Carrier

The Carrier-enabled FortiGate unit can be configured to assist with anti-overbilling measures. These measures ensure that the customer is only billed for connection time and data transfer that they actually use.

Anti-overbilling on the Carrier-enabled FortiGate unit involves:

- the administrator configuring the over billing settings in the GTP profile to notify the Gi firewall when a GTP tunnel is deleted
- the unit clearing the sessions when the Gi firewall receives a notification from the Gn/Gp firewall about a GTP tunnel being deleted This way, the Gi firewall prevents over billing by blocking traffic initiated by other users.

The three locations to configure anti-overbilling options include:

- **Network > Interface** — Edit a specific interface. Towards the bottom of the **Edit Interface** page, in the **Status** section, you can toggle **Gi Gatekeeper**.
- **System > Settings** — In the **Gi Gatekeeper Settings** section, set the **Context ID** and **Port** that anti-overbilling will take place on.
- **Security Profiles > GTP Profile** — Edit a specific GTP Profile. In the **Anti-Overbilling** section, edit the **Gi Firewall IP address**, **Port**, **Interface** and **Security Context ID**, to use for anti-overbilling measures.

For detailed options, see [Anti-Overbilling options](#).

## Logging events on the Carrier-enabled FortiGate unit

Logging on the Carrier-enabled FortiGate unit is just like logging on any other FortiOS unit. The only difference with FortiOS Carrier is that there are a few additional events that you can log beyond the regular ones. These additional events are covered here.

To change FortiOS Carrier specific logging event settings, go to **Security Profiles > GTP Profile** and edit a GTP profile. Expand the **Log** section to change the settings. For detailed options, see Log options.

The following information is contained in each log entry:

<b>Timestamp</b>	The time and date when the log entry was recorded
<b>Source IP address</b>	The sender's IP address.
<b>Destination IP address</b>	The receiver's IP address. The sender-receiver pair includes a mobile phone on the GPRS local network, and a device on a network external to the GPRS network, such as the Internet.
<b>Tunnel Identifier (TID)</b> <b>Tunnel Endpoint Identifier (TEID)</b>	An identifier for the start and endpoints of a GTP tunnel. This information uniquely defines all tunnels. It is important for billing information based on the length of time the tunnel was active and how much data passed over the tunnel.
<b>Message type</b>	For available message types, see Common message types on carrier networks.
<b>Packet status</b>	<p>What action was performed on the packet. This field matches the logging options while you are configuring GTP logging. See <a href="#">Logging events on the Carrier-enabled FortiGate unit on page 722</a>.</p> <p>The status can be one of forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited</p>
<b>Virtual domain ID or name</b>	A Carrier-enabled FortiGate unit can be divided into multiple virtual units, each being a complete and self-contained virtual FortiCarrier unit. This field indicates which virtual domain (VDOM) was responsible for the log entry. If VDOMs are not enabled on your unit, this field will be <code>root</code> .
<b>Reason to be denied if applicable</b>	If the packet that generated this log entry was denied or blocked, this field will include what part of FortiOS denied or blocked that packet. Such as firewall, antivirus, webfilter, or spamfilter.

An example of the above log message format is for a Tunnel deleted log entry. When a tunnel is deleted, the log entry contains the following information:

- Timestamp
- Interface name (if applicable)
- SGSN IP address (source IP)
- GGSN IP address (destination IP)
- Tunnel ID
- Tunnel duration time in seconds
- Number of messages sent to the SGSN
- Number of messages sent to the GGSN

## GTP message type filtering

FortiOS Carrier supports message filtering in GTP by the type of message.

This section includes:

### Common message types on carrier networks

Carrier networks include many types of messages — some concern the network itself, others are content moving across the network, and still others deal with handshaking, billing, or other administration based issues.

GTP contains two major parts GTP for the control plane (GTP-C) and GTP for user data tunnelling (GTP-U). Outside of those areas there are only unknown message types.

### GTP-C messages

GTP-C contains the networking layer messages. These address routing, versioning, and other similar low level issues.

When a subscriber requests a Packet Data Protocol (PDP) context, the SGSN will send a create PDP context request GTP-C message to the GGSN giving details of the subscriber's request. The GGSN will then respond with a create PDP context response GTP-C message which will either give details of the PDP context actually activated or will indicate a failure and give a reason for that failure. This is a UDP message on port 212.

GTP-C message types include Path Management Messages, Location Management Messages, and Mobility Management Messages.

#### Path Management Messages

Path management is used by one GSN to detect if another GSN is alive, or if it has restarted after a failure.

The path management procedure checks if a given GSN is alive or has been restarted after a failure. In case of SGSN restart, all MM and PDP contexts are deleted in the SGSN, since the associated data is stored in a volatile memory. In the case of GGSN restart, all PDP contexts are deleted in the GGSN.

#### Tunnel Management Messages

The tunnel management procedures are used to create, update, and delete GTP tunnels in order to route IP PDUs between an MS and an external PDN via the GSNs.

The PDP context contains the subscriber's session information when the subscriber has an active session. When a mobile wants to use GPRS, it must first attach and then activate a PDP context. This allocates a PDP context data structure in the SGSN that the subscriber is currently visiting and the GGSN serving the subscriber's access point.

Tunnel management procedures are defined to create, update, and delete tunnels within the GPRS backbone network. A GTP tunnel is used to deliver packets between an SGSN and a GGSN. A GTP tunnel is identified in each GSN node by a TEID, an IP address, and a UDP port number.

#### Location Management Messages

The location-management procedure is performed during the network-requested PDP context activation procedure if the GGSN does not have an SS7 MAP interface (i.e., Gc interface). It is used to transfer location

messages between the GGSN and a GTP-MAP protocol-converting GSN in the GPRS backbone network.

Location management subprocedures are used between a GGSN that does not support an SS7 MAP interface (i.e., Gc interface) and a GTP-MAP protocol-converting GSN. This GSN supports both Gn and Gc interfaces and is able to perform a protocol converting between GTP and MAP.

### Mobility Management Messages

The MM procedures are used by a new SGSN in order to retrieve the IMSI and the authentication information or MM and PDP context information in an old SGSN. They are performed during the GPRS attach and the inter-SGSN routing update procedures.

The MM procedures are used between SGSNs at the GPRS-attach and inter-SGSN routing update procedures. An identity procedure has been defined to retrieve the IMSI and the authentication information in an old SGSN. This procedure may be performed at the GPRS attach. A recovery procedure enables information related to MM and PDP contexts in an old SGSN to be retrieved. This procedure is started by a new SGSN during an inter-SGSN RA update procedure.

### GTP-U messages

GTP-U is focused on user related issues including tunneling, and billing. GTP-U message types include MBMS messages, and GTP-U and Charging Management Messages

### MBMS messages

Multimedia Broadcast and Multicast Services (MBMS) have recently begun to be offered over GSM and UMTS networks on UTRAN and GERAN radio access technologies. MBMS is mainly used for mobile TV, using up to four GSM timeslots for one MBMS connection. One MBMS packet flow is replicated by GGSN, SGSN and RNCs.

MBMS is split into the MBMS Bearer Service and the MBMS User Service. The MBMS User Service is basically the MBMS Service Layer and offers a Streaming- and a Download Delivery Method. The Streaming Delivery method can be used for continuous transmissions like Mobile TV services. The Download Method is intended for "Download and Play" services.

### GTP-U and Charging Management Messages

SGSNs and GGSNs listen for GTP-U messages on UDP port 2152.

GTP' (GTP prime) is used for billing messages. It uses the common GTP messages (GTP Version Not Supported, Echo Request and Echo Response) and adds additional messages related to billing procedures.

### Unknown Action messages

If the system doesn't know what type of message it is, it falls into this category. This is an important category of message because malformed messages may appear and need to be handled with security in mind.

Fortinet best practices dictate that you set **Unknown Action messages** to deny for security reasons.

---

## Configuring message type filtering in FortiOS Carrier

GPRS Tunneling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) traffic within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over their network via tunneling.

In the CLI, there is a keyword for each type of GTP message for both message filtering, and for message rate limiting.

GTP message rate limiting is only accessible from the CLI using the command `configure firewall gtp`.

### To configure GTP message type filtering - web-based manager

1. Go to **Security Profiles > GTP Profile**.
2. Select **Create New**.
3. Enter a name for this profile such as `msg_type_filtering`.
4. Select **Message Type Filtering** to expand it.
5. For each type of message in the list, select Allow or Deny. All messages are set to Allow by default.

Fortinet best practices dictate that the unknown message action should be set to **Deny** for security reasons as this will block malformed messages.

6. Optionally select and configure any other GTP features for this profile, such as logging.
7. Select **OK** to save the profile.
8. Apply the `msg_type_filtering` profile a security policy configured for GTP tunnel traffic.

### To configure GTP message filtering and block Unknown Message Action messages- CLI

```
config firewall gtp
  edit msg_type_filtering
    config message-filter
      set unknown-message-action deny
    next
  end
end
```

## Message Type Fields

Each of the following message types can be allowed or denied by your Carrier-enabled FortiGate unit depending on your carrier network and GTP traffic.

### Unknown Message Action

Set this message type to deny.

Many attempts to hack into a carrier network will result in this unknown message type and therefore it is denied for security reasons.

### Path Management Messages

Message Type	Used by	Description
Echo Request/Response	GTP-C, GTP-U, GTP'	Echo Request is sent on a path to another GSN to determine if the other node is alive. Echo Response is the reply.
Version not Supported	GTP-C, GTP-U, GTP'	There are multiple versions of GTP. Both devices communicating must use the same version of GTP, or this message will be the response.
Support Extension Headers Notification		Extensions are optional parts that a device can choose to support or not. If a device includes these extensions, it must include headers for the extensions to sure ensure proper formatting.

### Tunnel Management Messages

Message Type	Used by	Description
Create PDP Context Request/ Response	GTP-C	Sent from an SGSN to a GGSN node as part of a GPRS PDP Context Activation procedure or the Network-Requested PDP Context Activation procedure. A valid request initiates the creation of a tunnel.
Update PDP Context Request/ Response	GTP-C	Used when PDP Context information changes, such as when a mobile device changes location.
Delete PDP Context Request/ Response	GTP-C	Used to terminate a PDP Context, and confirm the context has been deleted.
Create AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS Anonymous Access PDP Context Activation. It is used to create a tunnel between a context in the SGSN and a context in the GGSN.
Delete AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS PDP Anonymous Access Context Deactivation procedure to deactivate an activated PDP Context. It contains Cause and Private Extension Information Elements

Message Type	Used by	Description
Error Indication	GTP-U	<p>Sent to the GGSN when a tunnel PDU is received for the following conditions:</p> <ul style="list-style-type: none"> <li>— No PDP context exists</li> <li>— PDP context is inactive</li> <li>— No MM context exists</li> <li>— GGSN deletes its PDP context when the message is received.</li> </ul>
PDU Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	<p>When receiving a Tunneled PDU (T-PDU), the GGSN checks if a PDP context is established for the given PDP address. If no PDP context has been established, the GGSN may initiate the Network-requested PDP Context Activation procedure by sending a PDU Notification Request to the SGSN.</p> <p><b>Reject Request</b> - Sent when the PDP context requested by the GGSN cannot be established.</p>

### Location Management Messages

Message Type	Used By	Description
Send Routing Information for GPRS Request/ Response	GTP-C	Sent by the GGSN to obtain location information for the MS. This message type contains the IMSI of the MS and Private Extension.
Failure Report Request/ Response	GTP-C	<p>Sent by the GGSN to the HLR when a PDU reject message is received.</p> <p>The GGSN requests the HLR to set the flag and add the GGSN to the list of nodes to report to when activity from the subscriber that owns the PDP address is detected.</p> <p>The message contains the subscriber IMSI and Private Extension</p>
Note MS GPRS Present Request/ Response	GTP-C	<p>When the HLR receives a message from a mobile with MDFG set, it clears the MDFG and sends the Note MS Present message to all GGSN's in the subscriber's list.</p> <p>This message type contains subscriber IMSI, GSN Address and Private Extension</p>

**Mobility Management Messages**

Message Type	Used By	Description
Identification Request/Response	GTP-C	Sent by the new SGSN to the old SGSN to request the IMSI for a MS when a GPRS Attach is done with a P-TMSI and the MS has changed SGSNs since the GPRS Detach was done.
SGSN context Request/ Response/ Acknowledge	GTP-C	Sent by the new SGSN to the old SGSN to request the MM and PDP Contexts for the MS.
Forward Relocation Request/ Response/ Complete/ Complete Acknowledge	GTP-C	Indicates mobile activation/deactivation within a Routing Area. This prevents paging of a mobile that is not active (visited VLR rejects calls from the HLR or applies Call Forwarding). Note that the mobile station does not maintain an attach/detach state.  SRNS contexts contain for each concerned RAB the sequence numbers of the GTP-PDUs next to be transmitted in uplink and downlink directions.
Relocation Cancel Request/ Response	GTP-C	Send to cancel the relocation of a connection.
Forward SRNS Context/ Context Acknowledge	GTP-C	This procedure may be used to trigger the transfer of SRNS contexts from RNC to CN (PS domain) in case of inter system forward handover.
RAN Information Relay	GTP-C	Forward the Routing Area Network (RAN) information.  A Routing Area (RA) is a subset of a GSM Location Area (LA). A RA is served by only one SGSN. Ensures that regular radio contact is maintained by the mobile

**MBMS messages**

Message Type	Used By	Description
MBMS Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	Notification of the radio access devices.
Create MBMS Context Request/ Response	GTP-C	Request to create an active MBMS context. The context will be pending until the response is received.  Once active, the MBMS context allows the MS to receive data from a specific MBMS source

Message Type	Used By	Description
Update MBMS Context Request/ Response	GTP-C	
Delete MBMS Context Request/ Response	GTP-C	Request to deactivate the MBMS context. When the response is received, the MBMS context will be inactive.

### GTP-U and Charging Management Messages

Message Type	Used By	Description
G-PDU	GTP-C, GTP-U	GPRS Packet data unit delivery message.
Node Alive Request/Response	GTP-C, GTP-U	Used to inform rest of network when a node starts service.
Redirection Request/Response	GTP-C, GTP-U	Used to divert the flow of CDRs from the CDFs to another CGF when the sender is being removed, or they are used when the CGF has lost its connection to a downstream system.
Data Record Transfer Request/Response	GTP-C, GTP-U	Used to reliably transport CDRs from the point of generation (SGSN/GGSN) to non-volatile storage in the CGF

## GTP identity filtering

FortiOS Carrier supports a number of filtering methods based on subscriber identity such as APN filtering, IMSI filtering, and advanced filtering.

This section includes:

### IMSI on carrier networks

The International Mobile Subscriber Identity (IMSI) number is central to identifying users on a carrier network. It is a unique number that is assigned to a cell phone or mobile device to identify it on the GSM or UTM network.

Typical the IMSI number is stored on the SIM card of the mobile device and is sent to the network as required.

An IMSI number is 15 digits long, and includes the Mobile Country Code (MCC), Mobile Network Code (MNC), and Mobile Station Identification Number (MSIN).

#### IMSI codes

The Home Network Identity (HNI) is made up of the MCC and MNC. The HNI is used to fully identify a user's home network. This is important because some large countries have more than one country code for a single carrier. For example a customer with a mobile carrier on the East Coast of the United States would have a different MCC than a customer on the West Coast with the same carrier because even though the MNC would be the same the MCC would be different — the United States uses MCCs 310 to 316 due to its size.

If an IMSI number is not from the local carrier's network, IMSI analysis is performed to resolve the number into a Global Title which is used to access the user's information remotely on their home carrier's network for things like billing and international roaming.

### Other identity and location based information elements

IMSI focuses on the user, their location, and carrier network. There are other numbers used to identify different user related Information Elements (IE).

These identity and location based elements include:

- Access Point Number (APN)
- Mobile Subscriber Integrated Services Digital Network (MSISDN)
- Radio Access Technology (RAT) type
- User Location Information (ULI)
- Routing Area Identifier (RAI)
- International Mobile Equipment Identity (IMEI)

### Access Point Number (APN)

The Access Point Number (APN) is used in GPRS networks to identify an IP packet data network that a user wants to communicate with. The Network Identifier describes the network and optionally the service on that network that the GGSN is connected to. The APN also includes the MCC and MCN, which together locate the network the GGSN belongs to. An example of an APN in the Barbados using Digicel as the carrier that is connecting to the Internet is `internet.mcc342.mnc750.gprs`.

When you are configuring your Carrier-enabled FortiGate unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

The access point can then be used in a DNS query to a private DNS network. This process (called APN resolution) gives the IP address of the GGSN which serves the access point. At this point a PDP context can be activated.

### Mobile Subscriber Integrated Services Digital Network (MSISDN)

This is a 15-digit number that, along with the IMSI, uniquely identifies a mobile user. Normally this number includes a 2-digit country code, a 3-digit national destination code, and a 10-digit subscriber number or the phone number of the mobile device, and because of that may change over time if the user changes their phone number. The MSISDN number follows the ITU-T E.164 numbering plan.

### Radio Access Technology (RAT) type

The RAT type represents the radio technology used by the mobile device. This can be useful in determining what services or content can be sent to a specific mobile device. FortiOS Carrier supports:

- **UMTS Terrestrial Radio Access Network (UTRAN)**, commonly referred to as 3G, routes many types of traffic including IP traffic. This is one of the faster types.
- **GSM EDGE Radio Access Network (GERAN)** is a key part of the GSM network which routes both phone calls and data.
- **Wireless LAN (WLAN)** is used but not as widely as the other types. It is possible for the mobile device to move from one WLAN to another such as from an internal WLAN to a commercial hot spot.
- **Generic Access Network (GAN)** can also be called unlicensed mobile access (UMA). It routes voice, data, and SIP over IP networks. GAN is commonly used for mobile devices that have a dual-mode and can hand-off between GSM and WLANs.
- **High Speed Packet Access (HSPA)** includes two other protocols High Speed Downlink and Uplink Packet Access protocols (HSDPA and HSUPA respectively). It improves on the older WCDMA protocols by better using the radio bandwidth between the mobile device and the radio tower. This results in an increased data transfer rate for the user.

RAT type is part of advanced filtering configuration. See [Configuring advanced filtering in FortiOS Carrier](#).

### User Location Information (ULI)

Gives Cell Global Identity/Service Area Identity (CGI/SAI) of where the mobile station is currently located. The ULI and the RAI are commonly used together to identify the location of the mobile device.

ULI is part of advanced filtering configuration. See [Configuring advanced filtering in FortiOS Carrier](#).

### Routing Area Identifier (RAI)

Routing Areas (RAs) divide the carrier network and each has its own identifier (RAI). When a mobile device moves from one routing area to another, the connection is handled by a different part of the network. There are normally multiple cells in a routing area. There is only one SSGN per routing area. The RAI and ULI are commonly used to determine a user's location.

RAI is part of advanced filtering configuration. See [Configuring advanced filtering in FortiOS Carrier](#).

### International Mobile Equipment Identity (IMEI)

IMEI is a unique 15-digit number used to identify mobile devices on mobile networks. It is very much like the MAC address of a TCP/IP network card for a computer. It can be used to prevent network access by a stolen phone — the carrier knows the mobile phone's IMEI, and when it is reported stolen that IMEI is blocked from accessing the carrier network no matter if it has the same SIM card as before or not. It is important to note that the IMEI stays with the mobile phone or device where the other information is either location based or stored on the removable SIM card.

IMEI type is part of advanced filtering configuration. See [Configuring advanced filtering in FortiOS Carrier](#).

### When to use APN, IMSI, or advanced filtering

At first glance APN, IMSI, and advanced filtering have parts in common. For example two can filter on APN, and another two can filter on IMSI. The difficulty is knowing when to use which type of filtering.

### Identity filtering comparison

Filtering type	Filter on the following data:	When to use this type of filtering
APN	APN	Filter based on GTP tunnel start or destination
IMSI	IMSI, MCC-MNC	Filter based on subscriber information
Advanced	PDP context, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI	When you want to filter based on: <ul style="list-style-type: none"> <li>• user phone number (MSISDN)</li> <li>• what wireless technology the user employed • to get on the network (RAT type)</li> <li>• user location (ULI and RAI)</li> <li>• handset ID, such as for stolen phones (IMEI)</li> </ul>

APN filtering is very specific — the only identifying information that is used to filter is the APN itself. This will always be present in GTP tunnel traffic, so all GTP traffic can be filtered using this value.

IMSI filtering can use a combination of the APN and MCC-MNC numbers. The MCC and MNC are part of the APN, however filtering on MCC-MNC separately allows you to filter based on country and carrier instead of just the destination of the GTP Tunnel.

Advanced filtering can go into much deeper detail covering PDP contexts, MSISDN, IMEI, and more not to mention APN, and IMSI as well. If you can't find the information in APN or IMSI that you need to filter on, then use Advanced filtering.

## Configuring APN filtering in FortiOS Carrier

To configure APN filtering go to **Security Profiles > GTP Profile**. Select a profile or create a new one, and expand **APN filtering**.

When you are configuring your Carrier-enabled FortiGate unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

<b>Enable APN Filter</b>	Select to enable filtering based on APN value.
<b>Default APN Action</b>	Select either Allow or Deny for all APNs that are not found in the list. The default is Allow.
<b>Value</b>	Displays the APN value for this entry. Partial matches are allowed using wildcard. For example <code>*.mcc333.mcn111.gprs</code> would match all APNs from country 333 and carrier 111 on the gprs network.
<b>Mode</b>	<p>Select one or more of the methods used to obtain APN values.</p> <p>Mobile Station provided - The APN comes from the mobile station where the mobile device connected. This is the point of entry into the carrier network for the user's connection.</p> <p>Network provided - The APN comes from the carrier network.</p> <p>Subscription Verified - The user's subscription has been verified for this APN. This is the most secure option.</p>
<b>Action</b>	One of allow or deny to allow or block traffic associated with this APN.
<b>Delete icon</b>	Select to remove this APN entry from the list.
<b>Edit icon</b>	Select to change the information for this APN entry.
<b>Add APN</b>	<p>Select to add an APN to the list. Not active while creating GTP profile, only when editing an existing GTP profile.</p> <p>Save all changes before adding APNs. A warning to this effect will be displayed when you select the <b>Add APN</b> button.</p>

The Add APN button is not activated until you save the new GTP profile. When you edit that GTP profile, you will be able to add new APNs.

## Configuring IMSI filtering in FortiOS Carrier

In many ways the IMSI on a GPRS network is similar to an IP address on a TCP/IP network. Different parts of the number provide different pieces of information. This concept is used in IMSI filtering on FortiOS Carrier.

To configure IMSI filtering go to **Security Profiles > GTP Profile** and expand **IMSI filtering**.

While both the APN and MCC-MCN fields are optional, without using one of these fields the IMSI entry will not be useful as there is no information for the filter to match.

<b>Enable IMSI Filter</b>	Select to turn on IMSI filtering.
<b>Default IMSI Action</b>	<p>Select Allow or Deny. This action will be applied to all IMSI numbers except as indicated in the IMSI list that is displayed.</p> <p>The default value is Allow.</p>
<b>APN</b>	<p>The Access Point Number (APN) to filter on.</p> <p>This field is optional.</p>
<b>MCC-MNC</b>	<p>The Mobile Country Code (MCC) and Mobile Network Code (MNC) to filter on. Together these numbers uniquely identify the carrier and network of the GGSN being used.</p> <p>This field is optional.</p>
<b>Mode</b>	<p>Select the source of the IMSI information as one or more of the following:</p> <p><b>Mobile Station provided</b> - the IMSI number comes from the mobile station the mobile device is connecting to.</p> <p><b>Network provided</b> - the IMSI number comes from the GPRS network which could be a number of sources such as the SGSN, or HLR.</p> <p><b>Subscription Verified</b> - the IMSI number comes from the user's home network which has verified the information.</p> <p>While Subscription Verified is the most secure option, it may not always be available. Selecting all three options will ensure the most complete coverage.</p>
<b>Action</b>	Select the action to take when this IMSI information is encountered. Select one of Allow or Deny.
<b>Delete Icon</b>	Select the delete icon to remove this IMSI entry.
<b>Edit Icon</b>	Select the edit icon to change information for this IMSI entry.
<b>Add IMSI</b>	<p>Select to add an IMSI to the list. Not active while creating GTP profile, only when editing an existing GTP profile.</p> <p>Save all changes before adding IMSIs. A warning to this effect will be displayed when you select the <b>Add IMSI</b> button.</p>

## Configuring advanced filtering in FortiOS Carrier

Compared to ADN or IMSI filtering, advanced filtering is well named. Advanced filtering can be viewed as a catch-all filtering option — if ADN or IMSI filtering doesn't do what you want, then advanced filtering will. The advanced filtering can use more information elements to provide considerably more granularity for your filtering.

<b>Enable</b>	Select to turn on advanced filtering.
<b>Default Action</b>	Select Allow or Deny as the default action to take when traffic does not match an entry in the advanced filter list .
<b>Messages</b>	<p>Optionally select one or more types of messages this filter applies to:</p> <p>Create PDP Context Request, Create PDP Context Response, Update PDP Context Request, or Update PDP Context Response.</p> <p>Selecting <b>Create PDP Context Response</b> or <b>Update PDP Context Response</b> limits RAT type to only GAN and HSPA, and disables the APN, APN Mode, IMSI, MSISDN, ULI, RAI, and IMEI fields.</p> <p>To select <b>Update PDP Context Request</b>, APN Restriction must be set to <b>all</b>. Selecting <b>Update PDP Context Request</b> disables the APN, MSISDN, and IMEI fields.</p> <p>if all message types are selected, only the RAT Types of GAN and HSPA are available to select.</p>
<b>APN Restriction</b>	APN Restriction either allows all APNs or restricts the APNs to one of four categories — Public-1, Public-2, Private-1, or Private-2. This can also be combined with a specific APN or partial APN as well as specifying the APN mode.
<b>RAT Type</b>	Select one or more of the Radio Access Technology Types listed. These fields control how a user accesses the carrier's network. You can select one or more of UTRAN, GERAN, WLAN, GAN, HSPA, or any.
<b>ULI</b>	<p>The user location identifier. Often the ULI is used with the RAI to locate a user geographically on the carrier's network.</p> <p>The ULI is disabled when <b>Create PDP Context Response</b> or <b>Update PDP Context Response</b> messages are selected.</p>
<b>RAI</b>	<p>The router area identifier. There is only one SGSN per routing area on a carrier network. This is often used with ULI to locate a user geographically on a carrier network.</p> <p>The RAI is disabled when <b>Create PDP Context Response</b> or <b>Update PDP Context Response</b> messages are selected.</p>

<b>IMEI</b>	<p>The International Mobile Equipment Identity. The IMEI uniquely identifies mobile hardware, and can be used to block stolen equipment.</p> <p>The IMEI is only available when <b>Create PDP Context Request</b> or no messages are selected.</p>
<b>Action</b>	<p>Select <b>Allow</b> or <b>Deny</b> as the action when this filter matches traffic.</p> <p>The default is Allow.</p>
<b>Delete Icon</b>	Select to delete this entry from the list.
<b>Edit Icon</b>	Select to edit this entry.
<b>Add</b>	<p>Select to add an advanced filter to the list. Not active while creating GTP profile, only when editing an existing GTP profile.</p> <p>Save all changes before adding advanced filters. A warning to this effect will be displayed when you select the <b>Add</b> button.</p>

## SCTP Concepts

As of FortiOS version 5.0, the FortiGate natively handles SCTP (Stream Control Transport Protocol) traffic, as an alternative to TCP and UDP for use in Carrier networks. The FortiGate handles SCTP as if it would any other traffic.

### Overview

SCTP is a connection-oriented transport protocol that overcomes some of the limitations of both TCP and UDP that prevent reliable transfer of data over IP-based networks (such as those used by telephony systems and carrier networks). The 'Stream' in SCTP refers to the sequence of user messages or packets that are considered at the same time to be individual objects and also treated as a whole by networked systems. SCTP is less vulnerable to congestion and flooding due to more advanced error handling and flood protection built into the protocol.

### SCTP features as compared to TCP and UDP

Feature	SCTP	TCP	UDP
State required at each endpoint	yes	yes	no
Reliable data transfer	yes	yes	no
Congestion control and avoidance	yes	yes	no
Message boundary conservation	yes	no	yes

Feature	SCTP	TCP	UDP
Path MTU discovery and message fragmentation	yes	yes	no
Message bundling	yes	yes	no
Multi-homed hosts support	yes	no	no
Multi-stream support	yes	no	no
Unordered data delivery	yes	no	yes
Security cookie against SYN flood attack	yes	no	no
Built-in heartbeat (reachability check)	yes	no	N/A

All of these features are built into the design of the Protocol, and the structure of SCTP packets and networks. The FortiGate unit interprets the traffic and provides the necessary support for maintenance and verification features, but the features are not FortiGate specific. These features are documented in greater detail below.

### State required at each endpoint

Constant back and forth acknowledgement and content verification messages are sent between all SCTP peer endpoints, and all endpoints' state machine actions must be synchronized for traffic to flow.

### Reliable data transfer

SCTP places data and control information (eg. source, destination, verification) into separate messages, both sharing the same header in the same SCTP packet. This allows for constant verification of the contained data at both ends and along the path, preventing data loss or fragmentation. As well, data is not sent in an interruptible stream as in TCP.

### Congestion control and avoidance

Built-in, constantly updating path detection and monitoring automatically redirect packets along alternate paths in case of traffic congestion or inaccessible destinations. For deliberate/malicious congestion control, see the below section on [Security cookie against SYN flood attack](#).

### Message boundary conservation

SCTP is designed in such a way that no matter how messages are divided, redirected, or fragmented, the message boundaries will be maintained within the packets, and all messages cannot be appended without tripping verification mechanisms.

### Path MTU discovery and message fragmentation

SCTP is capable of Path Maximum Transmission Unit discovery, as outlined in RFC4821. Two specific alterations have been made to how SCTP handles MTU. First, that endpoints will have separate MTU estimates for each possible multi-homed endpoint. Second, that bundled message fragments (as explained below) will be directed based on MTU calculations, so that retransmissions (if necessary) will be sent without delay to alternate addresses.

### Message bundling

SCTP is a message-oriented protocol, which means that despite being a streaming data protocol, it transports a sequence of specific messages, rather than transporting a stream of bytes (like TCP). Since some data transmissions are small enough to not require a complete message's worth of content, so multiple pieces of content will be transmitted simultaneously within the messages.

### Multi-homed hosts support

SCTP supports multi-homing, which is a network structure in which one or multiple sources/destinations has more than one IP address. SCTP can adapt to multi-homing scenarios and redirect traffic to alternate IP addresses in case of failure.

### Multi-stream support

Due to the message bundling feature allowing for multiple pieces of content to be sent in messages at once, SCTP can 'multi-stream' content, by deliberately dividing it among messages at a fixed rate, so that multiple types of content (eg. both images and text) can be loaded at once, at the same pace.

### Unordered data delivery

With control messages in every packet to provide verification of any packet's data and its place in the stream, the data being transmitted can actually arrive in any order, and verify that all has arrived or that some is missing.

### Security cookie against SYN flood attack

Since every packet contains verification of its place in the stream, it makes it easy for the protocol to detect when redundant, corrupted or malicious packets flood the path, and they are automatically dropped when necessary.

### Built-in heartbeat (reachability check)

Endpoints automatically send specific control chunks among the other SCTP packet information to peer endpoints, to determine the reachability of the destination. Heartbeat acknowledgement packets are returned if the destination is available.

## SCTP Firewall

FortiGate stateful firewalls will protect and inspect SCTP traffic, according to RFC4960. SCTP over IPsec VPN is also supported. The FortiGate device is inserted as a router between SCTP endpoints. It checks SCTP Syntax for the following information:

- Source and destination port
- Verification Tag
- Chunk type, chunk flags, chunk length
- Sequence of chunk types
- Associations

The firewall also oversees and maintains several SCTP security mechanisms:

- SCTP four-way handshake
- SCTP heartbeat
- NAT over SCTP

The firewall has IPS DoS protection against known threats to SCTP traffic, including INIT/ACK flood attacks, and SCTP fuzzing.

## Troubleshooting

This section offers troubleshooting options for Carrier-related issues.

This section includes:

### FortiOS Carrier diagnose commands

This section includes diagnose commands specific to FortiOS Carrier features such as GTP.

#### GTP related diagnose commands

This CLI command allows you to gain information on GTP packets, logs, statistics, and other information.

```
diag firewall gtp <command>
```

apn list <gtp_profile>	The APN list entries in the specified GTP profile
auth-ggsns show <gtp_profile>	The authorized GGSNs entries for the specified GTP profile. Any GGSNs not on this list will not be recognized.
auth-sgsns show <gtp_profile>	The authorized SGSNs list entries for the specified GTP profile. Any SGSNs not on this list will not be recognized.
handover-grp show <gtp_profile>	The handover group showing the range of allowed handover group IP addresses. The handover group acts like a white list of allowed GTP addresses with a default deny at the end — if the GTP address is not on the list, it is denied.
ie-remove-policy list <gtp_profile>	List of IE policies in the IE removal policy for this GTP profile. The information displayed includes the message count for this policy, the length of the SGSN, the list of IEs, and list of SGSN IP addresses.
imsi list <gtp_profile>	IMSI filter entries for this GTP profile. The information displayed includes the message count for this filter, length of the IMSI, the length of the APN and IMSI, and of course the IMSI and APN values.
invalid-sgsns-to-long list <gtp_profile>	List of SGSNs that do not match the filter criteria. These SGSNs will be logged.
ip-policy list <gtp_profile>	List the IP policies including message count for each policy, the action to take, the source and destination IP addresses or ranges, and masks.
noip-policy <gtp_profile>	List the non-IP policies including the message count, which mode, the action to take, and the start and end protocols to be used by decimal number.

	Select list or flush.
path {list   flush}	List the GTP related paths in FortiOS Carrier memory.  Flush the GTP related paths from memory.
policy list <gtp_policy>	The GTP advanced filter policy information for this GTP profile. The information displayed for each entry includes a count for messages matching this filter, a hexadecimal mask of which message types to match, the associated flags, action to take on a match, APN selection mode, MSISDN, RAT types, RAI, ULI, and IMEI.
profile list	Displays information about the configured GTP profiles.  You will not be able to see the bulk of the information if you do not log the output to a file.
runtime-stat flush	Select to flush the GTP runtime statistics from memory.
stat	Display the GTP runtime statistics — details on current GTP activity. This information includes how many tunnels are active, how many GTP profiles exist, how many IMSI filter entries, how many APN filter entries, advanced policy filter entries, IE remove policy filter entries, IP policy filter entries, clashes, and dropped packets.
tunnel {list   flush}	Select one of list or flush.  List lists all the GTP tunnels currently active.  Flush clears the list of active GTP tunnels. This does not clear the clash counter displayed in the <code>stat</code> command.

## Applying IPS signatures to IP packets within GTP-U tunnels

GTP-U (GTP user data tunnelling) tunnels carry user data packets, signaling messages and error information. GTP-U uses UDP port 2152. Carrier-enabled FortiGate units can apply IPS intrusion protection and detection to GTP-U user data sessions.

To apply IPS to GTP-U user data sessions, add an IPS Sensor to a profile and add the profile to a security policy that accepts GTP-U tunnels. The security policy Service field must be set to GTP or ANY to accept GTP-U packets.

The Carrier-enabled FortiGate unit intercepts packets with destination port 2152, removes the GTP header and handles the packets as regular IP packets. Applying an IPS sensor to the IP packets, the Carrier-enabled FortiGate unit can log attacks and pass or drop packets depending on the configuration of the sensor.

If the packet is GTP-in-GTP, or a nested tunnel, the packets are passed or blocked without being inspected.

### To apply an IPS sensor to GTP-U tunnels

1. Go to **Security Profiles > Intrusion Protection** and select Create New (+) to add an IPS Sensor.
2. Configure the IPS Sensor to detect attacks and log, drop, or pass attack packets.

See the Intrusion Protection section of the [FortiOS UTM Guide](#).

3. Go to **Policy & Objects > IPv4 Policy** and apply the IPS sensor to the security policy.
4. Go to **Policy & Objects > IPv4 Policy** and select Create New to add a security policy or select a security policy.
5. Configure the security policy to accept GTP traffic.  
In the security policy configure the source and destination settings to match the GTP traffic. Service to GTP or ANY so that the security policy accepts GTP traffic.
6. Select the GTP profile within the security policy.
7. Configure any other required security policy settings.
8. Select **OK** to save the security policy.

## GTP packets are not moving along your network

When GTP packets are not getting to their destination, this could be caused by any one of a number of issues. General troubleshooting principals apply here.

The following sections provide some suggestions on how to troubleshoot this issue:

- [Attempt to identify the section of your network with the problem](#)
- [Ensure you have an APN configured](#)
- [Check the logs and adjust their settings if required](#)
- [Check the routing table](#)
- [Perform a sniffer trace](#)
- [Generate specific packets to test the network](#)

### Attempt to identify the section of your network with the problem

The first step is to determine how widespread this problem is. Does it affect the whole GPRS network, or just one or two devices?

If the entire network is has this problem, the solution is likely a more general one such as ensuring the security policies allow GTP traffic to pass, the GTP profile specifies SSGNs and GSGNs, or ensuring the GTP general settings are not overly limiting.

If one part of the network is affected, the problem is more likely centered around configurations with those network devices specified such as the handover group, or authorized SGSNs/GGSNs. It is also possible that small portions of the network may have hardware related issues such as cabling or faulty hardware. This section does not address those issues, and assumes hardware is not the problem.

The handover group is a white list of GTP addresses allowed to handle GTP messages. If a device's address is not on this list, it will be denied.

### Ensure you have an APN configured

When you configure your GTP profile, ensure you first configure the APN. Without it, there will be no flow of traffic. The APN is used in nearly all GTP communications and without it, the Carrier-enabled FortiGate unit doesn't have the information it needs.

## Check the logs and adjust their settings if required

During normal operation, the log settings will show any problems on the network but may not provide the level of details required to fully troubleshoot the problem. The reason for this is that the level of detail required for troubleshooting would quickly overwhelm the daily logs without any real benefit.

GTP related events in the event log will have message IDs in the range 41216 to 41222. For more information on GTP log messages, see the Log Message Reference. For more information on logging in general, see the Logging and Reporting guide.

Once there is a problem to troubleshoot, check the logs to trace the traffic patterns and narrow down the possible sources of the problem. There may be enough detail for you to locate and fix the problem without changing the log settings.

Remember to set any changes you made to the log settings back to their original values when you are done troubleshooting. Otherwise, the amount of detail will overwhelm your logging.

However, if more detail is required you can change settings such as:

- Lower the Log Frequency number in GTP Profiles so fewer or no log messages are dropped. This will allow a more accurate picture of everything happening on the network, where you may have had only a partial picture before.
- Ensure all the GTP log events are enabled to provide you with a complete picture.
- Ensure that all relevant event types are enabled under **Log & Report > Log Config > Log Settings**.

For more information on GTP related logging, see Logging events on the Carrier-enabled FortiGate unit.

General information to look for in the logs includes:

- Are all packets having problems or just certain types?
- Are all devices on the network having problem, or just certain devices?
- Is it just GTP traffic that is having problems or are all types of traffic having the same problem?

## Check the routing table

On any network, the routing table determines how packets reach their destination. This is also true on a carrier network.

If the Carrier-enabled FortiGate unit is running in NAT mode, verify that all desired routes are in the routing table — local subnets, default routes, specific static routes, and dynamic routing protocols. For complete information, it is best to check the routing table in the CLI. This method provides more complete information.

If VDOMs are enabled on your Carrier-enabled FortiGate unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

### To check the routing table using the CLI

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
```

```
* - candidate default

S* 0.0.0.0/0 [10/0] via 192.168.183.254, port2
S 1.0.0.0/8 [10/0] via 192.168.183.254, port2
S 2.0.0.0/8 [10/0] via 192.168.183.254, port2
C 10.142.0.0/23 is directly connected, port3
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C 192.168.182.0/23 is directly connected, port2
```

Examining an entry from the routing table above:

```
B 10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

<b>B</b>	BGP. The routing protocol used.
<b>10.160.0.0/23</b>	The destination of this route including netmask.
<b>[20/0]</b>	20 indicates administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF
<b>10.142.0.74</b>	The gateway, or next hop.
<b>port3</b>	The interface used by this route.
<b>2d18h02m</b>	How old this route is, in this case almost three days old.

## Perform a sniffer trace

When troubleshooting network traffic, it helps to look inside the headers of packets to determine if they are traveling along the route you expect. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your Carrier-enabled FortiGate unit has NP interfaces that are offloading traffic, this will change the sniffer trace. Before performing a trace on any NP interfaces, disable offloading on those interfaces.

## What can sniffing packets tell you

If you are running a constant traffic application such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the Carrier-enabled FortiGate unit, if the ARP resolution is correct, and if the traffic is being sent back to the source as expected.

Sniffing packets can also tell you if the Carrier-enabled FortiGate unit is silently dropping packets for reasons such as RPF (Reverse Path Forwarding), also called Anti Spoofing. This prevents an IP packet from being forwarded if its source IP address either does not belong to a locally attached subnet (local interface), or be a hop on the routing between the FortiOS Carrier and another source (static route, RIP, OSPF, BGP). Note that RPF can be disabled by turning on asymmetric routing in the CLI (`config system setting, set asymmetric enable`), however this will disable stateful inspection on the Carrier-enabled FortiGate unit and consequently cause many features to be turned off.

If you configure virtual IP addresses on your Carrier-enabled FortiGate unit, the unit will use those addresses in preference to the physical IP addresses. If not configured properly, secondary IP addresses can cause a broadcast storm. You will notice the secondary address being preferred when you are sniffing packets because all the traffic will be using the virtual IP addresses. This is due to the ARP update that is sent out when the VIP address is configured.

### How to sniff packets

The general form of the internal FortiOS packet sniffer command is:

```
diag sniffer packet <interface_name> <'filter'> <verbose> <count>
```

To stop the sniffer, type `CTRL+C`.

<b>&lt;interface_name&gt;</b>	The name of the interface to sniff, such as <code>port1</code> or <code>internal</code> . This can also be <code>any</code> to sniff all interfaces.
<b>&lt;'filter'&gt;</b>	What to look for in the information the sniffer reads. <code>none</code> indicates no filtering, and all packets will be displayed as the other arguments indicate.  The filter must be inside single quotes (').
<b>&lt;verbose&gt;</b>	The level of verbosity as one of:  <ul style="list-style-type: none"> <li><b>1</b> - print header of packets</li> <li><b>2</b> - print header and data from IP of packets</li> <li><b>3</b> - print header and data from Ethernet of packets</li> </ul>
<b>&lt;count&gt;</b>	The number of packets the sniffer reads before stopping. If you don't put a number here, the sniffer will run forever until you stop it with <code>&lt;CTRL C&gt;</code> .

For a simple sniffing example, enter the CLI command `diag sniffer packet port1 none 1 3`. This will display the next 3 packets on the `port1` interface using no filtering, and using verbose level 1. At this verbosity level you can see the source IP and port, the destination IP and port, action (such as `ack`), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets, and 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diag sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]
0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh 3177924955 ack 1854307757

0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh 1854307757 ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh 4225311614 ack 3314279933
```

### Generate specific packets to test the network

If some packets are being delivered as expected while others are not, or after you believe you have fixed the problem, it is a good idea to generate specific traffic to test your network.

For example if you discover through log messages and packet sniffing that Create PDP Context Request messages are not being delivered between two SGSNs, you can generate those specific messages on your network to confirm they are the problem, and later that you have solved the problem and they are now being delivered as expected.

This step requires a third party traffic generation tool, either hardware or software. This is not supported by Fortinet.

## Chapter 6 - PCI DSS Compliance

This FortiOS Handbook chapter contains the following sections:

[Configuring FortiGate units for PCI DSS compliance on page 749](#) explains the Payment Card Industry Data Security Standard (PCI DSS). It provides information about configuring your network and FortiGate unit to help you comply with PCI DSS requirements.

### FortiOS 5.4 PCI DSS compliance new features

()

## Configuring FortiGate units for PCI DSS compliance

This chapter provides information about configuring your network and FortiGate unit to help you comply with PCI DSS requirements. There is also some description of other Fortinet products that can help you with PCI DSS compliance.

### Introduction to PCI DSS

The primary source of information for your PCI DSS compliance program is the Payment Card Industry (PCI) Data Security Standard itself. [Version 3.1](#) of the standard was published in April 2015. The following is a brief summary of PCI DSS.

#### What is PCI DSS?

The Payment Card Industry Data Security Standard (PCI DSS) sets data handling requirements for organizations that hold, process, or exchange cardholder information.

#### What is the Cardholder Data Environment

Throughout the PCI DSS requirements, there are references to the Cardholder Data Environment (CDE). The CDE is the computer environment wherein cardholder data is transferred, processed, or stored, and any networks or devices directly connected to that environment.

#### PCI DSS objectives and requirements

PCI DSS consists of 7 control objectives and 12 requirements.

#### PCI DSS Control Objectives and Requirements

Control Objective	Requirement	Fortinet Solution
<b>Build and Maintain a Secure Network and Systems</b>	<b>1.</b> Install and maintain a firewall configuration to protect cardholder data	FortiGate firewall functionality. See <a href="#">Security policies for the CDE network on page 755</a>
	<b>2.</b> Do not use vendor - supplied defaults for system passwords and other security parameters	FortiDB vulnerability assessment and auditing  FortiWeb web application password checking  See <a href="#">Password complexity and change requirements on page 761</a>

Control Objective	Requirement	Fortinet Solution
<b>Protect Cardholder Data</b>	<b>3.</b> Protect stored cardholder data	FortiDB vulnerability assessment and monitoring  FortiWeb web application firewall  See <a href="#">Protecting stored cardholder data on page 758</a>
	<b>4.</b> Encrypt transmission of cardholder data across open, public networks	FortiGate IPsec VPN. See <a href="#">Protecting communicated cardholder data on page 758</a>
<b>Maintain a Vulnerability Management Program</b>	<b>5.</b> Protect all systems against malware and regularly update antivirus software or programs	FortiGate integrated AV  FortiClient integrated AV  FortiMobile integrated AV  FortiMail integrated AV  FortiGuard automated AV updates  See <a href="#">Protecting the CDE network from viruses on page 759</a>
	<b>6.</b> Develop and maintain secure systems and applications	FortiDB vulnerability assessment, auditing and monitoring  FortiWeb web application security  FortiGate Application Control
<b>Implement Strong Access Control Measures</b>	<b>7.</b> Restrict access to cardholder data by business need-to-know	FortiDB vulnerability assessment, auditing and monitoring.  See <a href="#">Restricting access to cardholder data on page 760</a>
	<b>8.</b> Identify and authenticate access to system components	FortiGate integrated database or hooks to Active Directory. See <a href="#">Controlling access to the CDE network on page 761</a>
	<b>9.</b> Restrict physical access to cardholder data	Fortinet professional services in partnership with partner solutions

Control Objective	Requirement	Fortinet Solution
<b>Regularly Monitor and Test Networks</b>	<b>10.</b> Track and monitor all access to network resources and cardholder data	FortiDB auditing and monitoring  FortiAnalyzer event reporting  See <a href="#">Monitoring the network for vulnerabilities</a> .
	<b>11.</b> Regularly test security systems and processes	FortiDB vulnerability assessment  See <a href="#">Monitoring the network for vulnerabilities</a> .
<b>Maintain an Information Security Policy</b>	<b>12.</b> Maintain a policy that addresses information security for all personnel	FortiManager security policy management appliance

This chapter describes how the FortiGate's features can help your organization to be compliant with PCI DSS. Requirements that the FortiGate cannot enforce need to be met through organization policies with some means determined for auditing compliance.

Be sure to read the following wireless guidelines. Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that wireless networking has not been introduced into the CDE.

### Wireless guidelines

While wired networks usually connect fixed known workstations, wireless networks are more dynamic, introducing a different set of security concerns.

Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that unauthorized wireless networking has not been introduced into the CDE. Wireless networking could be introduced quite casually by adding a wireless device to a PC on the CDE network.

For all PCI DSS networks, whether they use wireless technology or not, the following requirement applies:

- Test for the presence of wireless access points by using a wireless analyzer at least quarterly or deploying a wireless IDS/IPS to identify all wireless devices in use. (11.1)

If your organization uses wireless networking outside the CDE network and the firewall prevents communication with the CDE network, the wireless network is outside the PCI DSS scope, but the firewall configuration must meet PCI DSS requirements.

If your organization uses wireless networking inside the CDE network, the wireless network is within the PCI DSS scope. For information about wireless network requirements, see [Wireless network security on page 756](#).

## Running PCI DSS compliance checks

FortiOS 5.4 allows you to run a compliance check either on demand or according to a schedule that automatically checks PCI DSS compliance at the global and/or VDOM level. The compliance check determines whether the FortiGate is compliant with each PCI DSS requirement by displaying an 'X' next to the non-compliant entries in the GUI logs.

The FortiGate runs at least 50 compliance checks that report on the status of a number of things including:

- Checking that out of stet ICMP packets are dropped
- The TCP end timeout is set
- SSH and SSL deep inspection with web filtering drops traffic from servers with invalid server certificates
- Verifying that IPS signatures, Application Control signatures, and Antivirus signatures are up to date
- Determining if Spyware/Malicious sites are being blocked by a web filtering policy
- Verifying that administrators are locked out after 3 login failures

For a complete list of compliance checks go to **Log & Report > Compliance Events**.

## Configuring PCI DSS compliance checking

Go to **System > Advanced > Compliance**, turn on compliance checking and configure a daily time to run the compliance check. Or you can select **Run Now** to run the compliance check on demand.

### Compliance

Run a series of compliance checks 

Daily Schedule

16:00:00.000

 Run Now

 Review results in Log & Report > Event Log -> Compliance

Go to **Log & Report > Compliance Events** to view compliance checking log messages that show the results of running compliance checks.

  <input type="text" value="Add Filter"/>				Log location: Disk	 Details
#	Date/Time	Level	Messages	Log Details 	
1	13:14:38		Check SSH-SSL deep inspection with WF enabled drops traffic from servers with invalic	<div> <div>General</div> <div> Date 05/16/2016  Time 13:14:38  Virtual Domain root  Log Description PCI DSS compliance check failed </div> </div> <div> <div>Action</div> <div> Action comp-check  Status high  Result   Reason FTNT-050142 </div> </div> <div> <div>Security</div> <div> Level  </div> </div> <div> <div>Compliance</div> <div> Module WF </div> </div>	
2	13:14:38		Check that Spyware / Malicious sites are being blocked by a WF policy		
3	13:14:38		Check that Phishing-related sites are being blocked by a WF policy		
4	13:14:38		Check that Bot net-related sites are being blocked by a WF policy		
5	13:14:38		Check that proxy related sites are being blocked by a WF policy		
6	13:14:38		Check that Hacking-related sites are being blocked by a WF policy		
7	13:14:38		Check that Spam-related sites are being blocked by a WF policy		
8	13:14:38		Check that P2P file sharing sites-related sites are being blocked by a WF policy		
9	13:14:38		Check that the IPS module has an updated IPS signature package		
10	13:14:38		Check that FGT performs IPS inspection on all traffic		
11	13:14:38		Check that there are no general exclusions to the activated IPS protections		
12	13:14:38		Check that the IPS Profile includes Protocol Anomalies protections		
13	13:14:38		Check the Severity-based Protections in the IPS Policy		
14	13:14:38		Check the IPS protection is enabled on Firewall policy		
15	13:14:38		Check the default IPS profiles have the default action set to block		

You can also configure compliance checking and set up the schedule from the CLI:

```
config system global
    set compliance-check {disable| enable}
    set compliance-check-time <time>
end
```

Use the following command to run on-demand compliance checking:

```
execute dsscc
```

## Per-VDOM compliance checking

If you have multiple VDOMs enabled compliance checking can be run separately for each VDOM.

Begin from the Global view by going to **System > Advanced > Compliance** and turning on compliance checking and configuring a daily time to run the compliance check. This compliance check daily schedule will be used to run compliance checks on individual VDOMs where compliance checking is enabled them.

You can also enable global compliance checking from the CLI:

```
config global
  config system global
    set compliance-check {disable| enable}
    set compliance-check-time <time>
  end
```

Then log onto each VDOM for which to enable compliance checking and go to **System > Advanced > Compliance**, and turn on compliance checking . You can also select **Run Now** to run a compliance check on that VDOM on demand.

From the CLI edit a VDOM and use the following command to enable compliance checking for that VDOM. The following example shows how to enable compliance checking for the root VDOM:

```
config vdom
  edit root
    config system settings
      set compliance-check enable
    end
```

From the CLI you can also log into a VDOM and use the following command to run on-demand compliance checking:

```
execute dsscc
```

From a VDOM GUI go to **Log & Report > Compliance Events** to view compliance checking log messages that show the results of running compliance checks.

## Compliance checking diagnose command

Use the following command to display diagnostic information about compliance checking:

```
diagnose debug application dssccd <debug_level>
```

## Network topology

The cardholder data environment must be protected against unauthorized access from the Internet and from other networks in your organization. FortiGate unit firewall functionality provides tight control over the traffic that can pass between the following network interfaces:

- Internet
- CDE wired LAN
- CDE wireless LAN
- Other internal networks

The figure below shows how the Cardholder Data Environment can be delineated in a typical network.

### Enterprise network with a cardholder data environment

#### Internet

The FortiGate unit has at least one network interface connected to the Internet. If your organization uses more than one Internet service provider, there could be additional network interfaces that function as a route to the Internet.

#### The CDE wired LAN

The CDE network typically contains point-of-sale (POS) terminals, databases, and servers. The only security policies between the CDE network and the Internet should be for encrypted connections. For remote point-of-sale terminals or off-site databases, VPN connections are required and they should use strong encryption. For a web server that handles online purchases, only HTTPS (SSL or TLS) connections can be permitted. The security

policies that enable these connections should have the narrowest possible definitions for source address, destination address and service.

PCI DSS does not require the CDE network to be isolated from the rest of your corporate LAN. But isolating the CDE network reduces the scope of required data protection measures and may reduce the scope of PCI DSS assessments that are periodically required.

### The CDE wireless LAN

Wireless networking is a special issue. Even if you do not use wireless technology you must monitor to ensure that unauthorized wireless access has not been added to the CDE network. For this purpose, the figure above shows a FortiAP device in the CDE. The FortiAP device can provide dedicated wireless monitoring, an access point, or both.

A small retail outlet could reduce costs by using a FortiWiFi unit, a FortiGate unit with integrated wireless networking. The FortiWiFi unit would have to be located where it could provide sufficient wireless monitoring (or access point) coverage for the entire premises.

### Other internal networks

Other internal networks such as your office LAN, unless they provide connection to the CDE, are not subject to PCI DSS requirements.

## Security policies for the CDE network

The FortiGate unit's firewall functionality is ideally suited to PCI DSS requirement 1.2.1, "Restrict inbound and outbound traffic to that which is necessary for the cardholder data environment, and specifically deny all other traffic." Security policies control the source, destination, and type of traffic passing between networks.

The PCI DSS standard includes requirements to document your network topology and configuration. As part of that requirement, and to assist the auditing of your network, make use of the **Comment** field available in FortiGate security policies. Describe the purpose of each policy.

### Controlling the source and destination of traffic

The source and destination are the first parameters you specify in a security policy. (Go to **Policy & Objects > IPv4 Policy** and select **Create New**.)

Name	<input type="text"/>
Incoming Interface	<input type="text" value="+"/>
Outgoing Interface	<input type="text" value="+"/>
Source	<input type="text" value="+"/>
Destination Address	<input type="text" value="+"/>

The **Interface** settings depend on network topology. The **Source** and **Destination Address** settings define the IP addresses to which the policy applies. These should be as narrow as possible, so that only the appropriate hosts are included. For example, if the destination is a server with a single IP address, the named **Destination Address** should be defined as that single address, not the entire subnet on which the server resides.

Addresses are defined in **Policy & Objects > Addresses**. Some addresses will be used in several security policies, so it is best to plan ahead and define the addresses first.

### Controlling the types of traffic in the CDE

The **Policy & Objects > Service** setting determines which types of traffic can pass based on protocol.

You can select a single protocol from the **Service** drop-down list. To add another protocol, select the green “+” button to access the **Service** drop-down list again. If several security policies will need the same list of services, consider creating a named service group. (Go to **Firewall Objects > Service > Groups**.) In the security policy, service groups are available at the bottom of the **Service** drop-down list.

### The default deny policy

All traffic not specifically allowed by a security policy that you create is blocked by the Implicit policy listed at the bottom of the **Policy & Objects > IPv4 Policy** page.

Implicit (2 - 2)						
2	Implicit Deny	all	all	always	ALL	Deny

You cannot delete this policy and you can edit the policy only to enable or disable logging of the traffic that it handles.

## Wireless network security

Scanning for rogue access points is the minimum requirement for wireless security. Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that wireless networking has not been introduced into the CDE.

If you use wireless networking, the wireless network is only within the PCI DSS scope if it can connect to the CDE.

### On-wire detection of rogue APs

FortiGate units include an “on-wire” detection technique that correlates the SSID MAC addresses of the unknown access points with MAC addresses detected on your wired networks. This helps to differentiate unrelated neighboring APs from security-compromising unauthorized APs connected to your network.

### Setting up rogue access point scanning

A FortiGate unit with a connected FortiAP unit can perform wireless scanning. Each of the FortiAP radios can act as a dedicated monitor or can perform scanning in the background while acting as a wireless access point.

Radio 1 operates in the 2.4GHz band and Radio 2 operates in the 5GHz band. Both bands should be monitored. The FortiAP unit(s) used for scanning must be located within the coverage area that would result if an access point were added to the CDE.

### To configure rogue AP scanning in a FortiAP profile

1. Go to **WiFi & Switch Controller > WIDS Profiles**.  
On some models, the menu is **WiFi & Switch Controller**.
2. Select an existing WIDS profile and edit it, or select **Create New**.
3. Make sure that **Enable Rogue AP Detection** is selected.

4. Select **Enable On-Wire Rogue AP Detection**.
5. Optionally, enable **Auto Suppress Rogue APs in Foreground Scan**.
6. Select **OK**.

### Viewing the results of rogue AP scanning

Go to **Monitor > Rogue AP Monitor** to view information about detected rogue wireless access points.

### Logging the results of rogue AP scanning

To ensure that detection of rogue access points is logged, go to **Log & Report > Log Settings**, enable **Event Logging** and select **WiFi activity event**.

### Securing a CDE network wireless access point

If your wireless network is within PCI DSS scope, it must meet the following requirements:

- Default settings such as SSID and passphrases must be changed.
- Use WPA/WPA2 security.
- Log wireless activity.

### Setting wireless security

On FortiGate units, go to **WiFi & Switch Controller > SSID** to configure wireless security settings for either a new or existing virtual access point.

#### WiFi Settings

SSID	<input type="text" value="fortinet"/>	
Security Mode	<input type="text" value="WPA2 Personal"/>	▼
Pre-shared Key	<input type="text"/>	(8 - 63 characters)
Broadcast SSID	<input checked="" type="checkbox"/>	
Schedule ⓘ	<input type="text" value="always"/>	▼

The default SSID for the FortiAP is “fortinet”. You must change this.

The **Security Mode** must be set to one of the WPA2 modes. Both WPA or WPA2 clients can be served. In the CLI, you can optionally select exclusively WPA or WPA2 operation.

WPA/WPA2-Enterprise **Authentication** uses separate logon credentials for each user. Either FortiGate user group security or an external RADIUS server performs the authentication. Optionally, certificate-based security can also be applied. WPA/WPA2-Personal authentication requires a single pre-shared key that is used by all clients and is thus less secure.

For detailed information about wireless access points, see the Deploying Wireless Networks chapter of the FortiOS Handbook.

### Logging wireless network activity

To ensure that wireless network activity is logged, go to **Log & Report > Log Settings**, enable **Event Logging** and select **WiFi activity event**.

### Protecting stored cardholder data

The Fortinet FortiDB and FortiWeb products can provide security for your sensitive cardholder data.

The Fortinet Database Security (FortiDB) device provides vulnerability assessment, database activity monitoring, auditing and monitoring.

The Fortinet FortiWeb Web Application Firewall deployed in front of public-facing web applications protects Web applications, databases, and the information exchanged between them. In particular, it addresses the PCI DSS requirements 6.5 and 6.6 regarding web application vulnerabilities such as cross-site scripting, SQL injection, and information leakage.

FortiGates support some web application firewall security features and allow you to offload selected HTTP and HTTPS traffic to an external FortiWeb device. To offload HTTP traffic to go **Security Fabric > Settings**, enable **HTTP service** and select FortiWeb.

### Protecting communicated cardholder data

If cardholder data must be communicated over an untrusted network, such as the Internet, use the FortiGate unit's IPsec VPN capability to exchange the data securely. If you support customer online transactions, use HTTPS (SSL or TLS encryption) for security. The relevant PCI DSS requirement is:

- Use strong cryptography and security protocols (for example, SSL/TLS, IPSEC, SSH, etc.) to safeguard sensitive cardholder data during transmission over open, public networks. (4.1)

This does not prescribe particular cryptography, but it can be interpreted as a requirement to follow industry best practices.

### Configuring IPsec VPN security

The security considerations for IPsec VPNs are encryption and authentication.

#### Encryption

Go to **VPN > IPsec Tunnels** to configure an IPsec VPN. In both Phase 1 and Phase 2 parts of the configuration, you select the encryption to use.

Encryption	3DES	Authentication	SHA256
Encryption	AES128	Authentication	SHA256

These are advanced settings, overriding defaults that are not necessarily the strongest algorithms. VPNs negotiate over standards, so you can list multiple proposed algorithms. The VPN will use the strongest encryption that both ends support.

Choose strong encryption. The available encryption algorithms in descending order of strength are AES256, AES192, AES128, 3DES, DES. DES encryption is the weakest with only a 64-bit key and does not meet the 80-bit key length minimum that PCI DSS requires.

The message digest (authentication) algorithms in descending order of strength are SHA512, SHA384, SHA256, SHA1 and MD5. MD5 is particularly weak and should be avoided.

## Authentication

VPN peers authenticate each other before establishing a tunnel. FortiGate units support two different authentication methods: pre-shared key and RSA signature (certificate). Certificates provide the best security. PCI DSS does not prohibit pre-shared keys, but you should limit access to the keys to the personnel who are responsible for the FortiGate units or other equipment at either end of the VPN.

## Configuring SSL VPN security

The SSL VPN configuration includes a choice of encryption algorithm. You can only configure encryption key algorithms for SSL VPN in the CLI:

```
config vpn ssl settings
    set algorithm {low | medium | high}
end
```

The default option of Medium at RC4 (128 bits) is acceptable, but the High option, AES (128/256 bits) and 3DES is more secure. The Low option, RC4 (64 bits), DES and higher does not meet PCI DSS requirements.

## Protecting the CDE network from viruses

PCI DSS requires the use of regularly updated antivirus protection. The antivirus functionality of the FortiGate unit protects both the FortiGate unit and the networks it manages. Workstations on these networks can be protected using FortiClient Endpoint Security. Both FortiGate and FortiClient antivirus protection can receive updates from Fortinet's FortiGuard service. Workstations can also use third-party antivirus applications with update services.

The FortiGate unit can enforce the use of antivirus software, denying unprotected workstations access to the network.

## Enabling FortiGate antivirus protection

The antivirus profile must apply AV scanning to all protocols. You also need to enable SSL inspection to include secure protocols in antivirus scanning. The extended AV database contains the largest number of virus signatures.

### To enable SSL inspection

1. Go to **Security Profiles > SSL/SSH Inspection**.
2. Set **Inspection Method** to **Full SSL Inspection**.
3. Set each listed protocol to **On** and then select **Apply**.

### To select the extended antivirus database

The antivirus database is selectable using the CLI:

```
config antivirus settings
    set default-db extended
```

end

For detailed information about the Antivirus feature, see the Security Profiles chapter of the FortiOS Handbook.

## Configuring antivirus updates

On the dashboard, check the **License Information** widget. The **Support Contract** section should indicate that the FortiGate is registered and show future expiry dates for the FortiGuard Antivirus license. If your FortiGate unit is not registered, you can register it from the License Information widget.

In the **FortiGuard Services** section, check the **Antivirus** field. If the service is unreachable, see the online Help for information about troubleshooting your connectivity to FortiGuard Services.

## Enforcing firewall use on endpoint PCs

PCI DSS requires you to “install personal firewall software on any mobile and/or employee-owned devices that connect to the Internet when outside the network (for example, laptops used by employees), and which are also used to access the network. (1.4)” Consider using the Endpoint Control feature of the FortiGate unit to enforce use of this software.

## Monitoring the network for vulnerabilities

There are several tools that can assist you in monitoring your network for vulnerabilities and provide evidence to the PCI DSS auditor of such monitoring.

### FortiGate logs

FortiGate units can be configured to send logs to FortiAnalyzer unit. In a larger network, this enables you to collect log information in a central location from several FortiGate units. You can also send logs to FortiCloud and to multiple syslog servers.

### Monitoring with other Fortinet products

In addition to your FortiGate unit and its FortiOS firmware, there are several other Fortinet products that can assist your organization to comply with PCI DSS requirements.

#### Fortinet Database Security (FortiDB)

A FortiDB appliance or FortiDB software can provide vulnerability scanning and activity monitoring for your databases. For more information about this product, see the Fortinet website, [www.fortinet.com](http://www.fortinet.com).

#### FortiWeb Web Application Security

If your organization engages in e-Commerce, you can use FortiWeb Application Security to protect your web servers against attack. The FortiWeb application protects against HTTP and XML-based attacks, guards against attempts to deface your websites, and scans web servers for vulnerabilities. For more information about this product, see the Fortinet website, [www.fortinet.com](http://www.fortinet.com).

## Restricting access to cardholder data

In addition to security policies and authentication governing access to the CDE, you can deploy the Fortinet Database Security (FortiDB) device, which provides vulnerability assessment, database activity monitoring, auditing and monitoring. You can also deploy FortiAuthenticator to increase authentication options.

## Controlling access to the CDE network

PCI DSS requires each user to be uniquely identified and authenticated. On the FortiGate unit, this applies to administrators and to users of SSL VPN and IPsec VPNs.

### Password complexity and change requirements

By default, the FortiGate unit admin account has no password. Be sure to define a password.

PCI DSS password requirements are:

- Require a minimum length of at least seven characters. (8.2.3)
- Contain both numeric and alphabetic characters. (8.2.3)
- Change user passwords/passphrases at least every 90 days. (8.2.4)

To facilitate creation of compliant administrator passwords, you can set a password policy. Go to **System > Settings** Select **Enable Password Policy**, enter the following and then select **Apply**.

The password policy does not apply to user passwords. Both password complexity and password expiry for users would need to be addressed by making them a policy in your organization.

#### ☒ Enable Password Policy

Minimum Length	<input type="text" value="8"/>	(8-128 characters)
Must Contain at Least	<input checked="" type="checkbox"/>	
	<input type="text" value="1"/>	Upper Case Letters
	<input type="text" value="0"/>	Lower Case Letters
	<input type="text" value="1"/>	Numbers (0-9)
	<input type="text" value="0"/>	Special Characters
Apply Password Policy to	<input checked="" type="checkbox"/> Administrator Password	<input type="checkbox"/> IPsec Pre-shared Key
Enable Password Expiration	<input checked="" type="checkbox"/> <input type="text" value="90"/>	(days)

<b>Minimum Length</b>	8 or more. (Field does not accept a value less than 8.)
<b>Must Contain</b>	At minimum, set a required number of <b>Numerical Digits</b> and either <b>Upper Case Letters</b> or <b>Lower Case Letters</b> .  Also setting a required number of <b>Non-alphabetic Letters</b> is acceptable.
<b>Apply Password Policy to</b>	Select <b>Administrator Password</b> .
<b>Enable Password Expiration</b>	Set to 90 days or less. The default is 90 days.

### Password non-reuse requirement

PCI DSS requires that passwords are not re-used to satisfy the change requirement:

- Do not allow an individual to submit a new password/phrase that is the same as any of the last four passwords/phrases he or she has used. (8.2.5)

FortiGate users don't set their own passwords. The super\_admin administrators can and so can admins with appropriate access. There is, however, no FortiGate-based mechanism to limit re-use of passwords.

### Administrator lockout requirement

PCI DSS requires a user account lockout for administrators to guard against unauthorized access attempts:

- Limit repeated access attempts by locking out the administrator after not more than six attempts. (8.1.6),
- Set the lockout duration to a minimum of 30 minutes or until an administrator enables the user ID. (8.1.7)

You can meet these requirements with the following CLI commands:

```
config system global
    set admin-lockout-threshold 6
    set admin-lockout-duration 1800
end
```

The threshold can be less than 6 and the lockout duration can be more than 1800.

### Administrator timeout requirement

PCI DSS requires:

- If a session has been idle for more than 15 minutes, require the user to re-authenticate to re-activate the terminal or session. (8.1.8)

By default, the idle timeout is five minutes. You can go to **System > Settings** and change the **Idle Timeout** timeout to any value up to the permitted value of 15 minutes.

### Administrator access security

To accommodate the requirement for unique identification of each user, the generic admin account should either be assigned to only one administrator or not used at all. You can create an administrator account for each administrator in **System > Administrators**.

You can also rename the admin administrator account to something that attackers are less likely to guess. To rename the admin administrator account you must go to **System > Administrators** and create a new administration account with the super\_admin administrator profile and then login with this new account and change the name of the admin administrator account.

If an administrator always works from the same workstation, consider using the Trusted Host feature. The administrator will be able to log in only from a trusted IP address. You can define up to three trusted IP addresses per administrator.

Administrative access must also be enabled per network interface. Go to **Network > Interfaces** to edit the interface settings. Enable administrative access only on interfaces where you would expect the administrator to connect. Allow only secure connection protocols, HTTPS for web-based access, SSH for CLI access.

### Remote access security

For remote access, PCI DSS requires two-factor authentication: a password and some other authentication, such as a smart token or certificate. This applies to employees, administrators, and third parties.

For remote access from the Internet, if possible you should also use the trusted hosts feature to limit the source addresses from which administrators can log into the FortiGate.

### SSL VPN users

For SSL VPN users, implement two-factor authentication by requiring users to have a certificate in addition to the correct password. Go to **VPN > SSL-VPN Settings**, enable **Require Client Certificate**.

### IPsec VPN users

If remote Users access your network using an IPsec VPN, you can implement two-factor authentication by adding a user group to a Remote Access IPsec VPN tunnel that requires two-factor authentication with FortiToken. This adds extended authentication (XAUTH) to the VPN and requires the user to use two-factor authentication in addition to the VPN authentication provided by the certificate or pre-shared key. As PCI DSS requires each user to have a unique identifier, you should already have user accounts and user groups defined.

# Chapter 7 - Firewall

This guide contains a number of different topics that, at its simplest, can be grouped into fundamental firewall topics such as policies, objects and network defense and topics that have to do with the optimization of the firewall such as WAN optimization, proxies and caching.

## Fundamentals

"[Firewall concepts](#)" on [page 787](#) explains the ideas behind the components, techniques and processes that are involved in setting up and running a firewall in general and the FortiGate firewall in particular. The premise here is that regardless of how experienced someone is with firewalls as they go through the process of configuring a firewall that is new to them they are likely to come across a term or setting that they may not be familiar with even if it is only in the context of the setting they are working in at the moment. FortiGate firewalls are quite comprehensive and can be very granular in the functions that they perform, so it makes sense to have a consistent frame of reference for the ideas that we will be working with.

Some examples of the concepts that will be addressed here are:

- "What is a Firewall?"
- "NAT"
- "IPv6"

"Firewall objects" describes the following firewall objects:

- Addressing
- Services
- Firewall Policies

"[Network defense](#)" on [page 872](#) describes various methods of defending your Network using the abilities of the FortiGate Firewall.

"[Object Configuration](#)" on [page 910](#) is similar to a cookbook in that it will refer to a number of common tasks that you will likely perform to get the full functionality out of your FortiGate firewall. Because of the way that firewalls are designed, performing many of the tasks requires that firewall components be set up in a number of different sections of the interface and be configured to work together to achieve the desired result. This section will bring those components all together as a straight forward series of instructions.

## FortiGate Firewall Components

The FortiGate firewall is made up of a number of different components that are used to build an impressive list of features that have flexibility of scope and granularity of control that provide protection that is beyond that provided by the basic firewalls of the past.

Some of the components that FortiOS uses to build features are:

- Interfaces
- VLANs
- Soft Switches

- Zones
- Predefined Addresses
- IP address based
- FQDN based
- Geography based
- Access Schedules
- Authentication
- Local User based
- Authentication Server based (Active Directory, Radius, LDAP)
- Device Based
- Configureable Services
- IPv4 and IPv6 protocol support

The features of FortiOS include but are not limited to:

- Security profiles, sometimes referred to as Unified Threat Management (UTM) or Next Generation Firewall (NGFW)
- Predefined firewall addresses (this includes IPv4 and IPv6, IP pools, . wildcard addresses and netmasks, and geography-based addresses)
- Monitoring traffic
- Traffic shaping and per-IP traffic shaping (advanced)
- Firewall schedules
- Services (such as AOL, DHCP and FTP)
- Logging traffic
- Quality of Service (QoS)
- Identity-based policies
- Endpoint security

## Firewall Optimization

There are a few different methodologies of optimization and most of these methodologies has been divided into:

- Concepts section - This will have the basic ideas behind the how and why of the topic. Because the number of topics is larger, the ideas are not as pervasive and the content is not so extensive as in the Fundamental section, some of the topics will include instructions on the configuration for that individual topic in order to keep the information fo granular topics together.
- Configuration section- Just like the Configuration section of the Fundamentals, this will be a cookbook style of documentation showing how to configure something that achieves a specific functionality from the FortiGate.

The optimization topics include:

- [Secure Web Gateway, WAN Optimization, Web Caching and WCCP](#)
- [Example topologies relevant to WAN Optimization](#)
- [Inside FortiOS: WAN Optimization](#)
- [WAN Optimization Concepts](#)
- [WAN Optimization Configuration](#)

- [Peers and authentication groups](#)
- [Web Cache Concepts](#)
- [Web Cache Configuration](#)
- [WCCP Concepts](#)
- [WCCP Configuration](#)
- [Web Proxy Concepts](#)
- [Web Proxy Configuration](#)
- [Explicit Proxy Concepts](#)
- [Explicit Proxy Configuration](#)
- [Transparent Proxy Concepts](#)
- [Transparent Proxy Configuration](#)
- [FTP Proxy Concepts](#)
- [FTP Proxy Configuration](#)
- [Diagnose commands for WAN Optimization](#)

## How does a FortiGate Protect Your Network?

The FortiGate firewall protects your network by taking the various components and using them together to build a kind of wall or access control point so that anyone that is not supposed to be on your network is prevented from accessing your network in anyway other than those approved by you. It also protects your network from itself by keeping things that shouldn't happen from happening and optimizing the flow of traffic so that the network is protected from traffic congestion that would otherwise impede traffic flow.

Most people have at one time or another played with the children's toy system that is made up of interlocking blocks. The blocks come in different shapes and sizes so that you can build structures to suit your needs and in your way. The components of the FortiGate firewall are similar. You are not forced to use all of the blocks all of the time. You mix and match them to get the results that you are looking for. You can build a very basic structure that's only function is to direct traffic in and out to the correct subnets or you can build a fortress that only allows specific traffic to specific hosts from specific hosts at specific times of day and that is only if they provide the credentials that have been pre-approved and all of the traffic is encrypted so that even when the traffic is out on the Internet it is private from the world. Just like the interlocking blocks, what you build is up to you, but chances are if you put them together the right way there isn't much that can't be built.

Here is one example of how the components could be put together to support the requirements of a network infrastructure design.

- Off the Internal interface you could have separate VLANs. One for each for the departments of Sales, Marketing and Engineering so that the traffic from the users on one VLAN does not intrude upon the hosts of the other VLANs and the department are isolated from one another for security reasons.
- To ease in the administration each of the VLAN sub-interfaces is made a member of a zone so that security policies that apply to all of the hosts on all of the VLANs can be applied to all of them at once.
- Using the addresses component each of the IP address ranges could be assigned a user friendly name so that they could be referred to individually and then for policies that would refer to them all as a whole the individual ranges to be made members of an address group.
- Firewall schedules could be created to address the differing needs of each of the groups so that Sales and Marketing could be allowed access to the Internet during regular business hours and the Engineering department could be allowed access during the lunch break.

- By setting up the outgoing policies to use FortiGuard Web-filtering the employees could be prevented from visiting inappropriate sites and thus enforcing the policies of the HR department.
- A couple of virtual IP addresses with port forwarding could be configured to allow users on the Internet to access a web server on the DMZ subnet using the company's only Public IP address without affecting the traffic that goes to the company's mail server that is hosted on a complete different computer.
- Even though the Web server on the same DMZ has an FTP service to allow for the uploading of web pages to the web server from the Marketing and Engineer teams, by placing a DENY policy on any FTP traffic from the Internet malicious users are prevented from abusing the FTP service.
- By monitoring the traffic as it goes through the policies you can verify that the policies are in working order.
- By using a combination of ALLOW and DENY policies and placing them in the correct order you could arrange for an outside contractor to be allowed to update the web site as well

These set of configurations is not extensive but it does give an idea of how different components can be mixed and matched to build a configuration that meets an organization's needs but at the same time protect it from security risks.

## What's new for Firewall in 5.6

### New Firewall Features in 5.6.4

The following list contains new firewall features added in FortiOS 5.6.4. Click on a link to navigate to that section for further information.

- [Using a FortiCache as a cache service on page 1027](#)

#### Using a FortiCache as a cache service

Some FortiGate devices don't have sufficient memory or disk space to run a cache service. This feature allows a FortiGate to connect to a FortiCache that has a higher cache capability than most FortiGates.

### New Firewall Features in 5.6.3

#### Multi-port support for Explicit Proxy (402775)

Support has been added for the use of multiple ports and port range in the explicit FTP or Web proxies. These changes have been added in both CLI and GUI.

CLI changes:

```
set http-incoming-port <port_low>[-<port_high>]
```

Where:

- `port_low` - the low value of the port
- `port_high` - the high value of the port

The `port_high` value can be omitted if `port_low` and `port_high` are the same.

## Nturbo support CAPWAP traffic and fix IPsec IPv6 firewall policy code typo (290708) (423323)

NTurbo is used for IPSEC+IPS case. The IPSEC SA info is passed to NTURBO as part of VTAG for control packet and will be used for the xmit.

If the packets need to go through IPSEC interface, the traffic will be always offloaded to Nturbo. But for the case that SA has not been installed to NP6 because of hardware limitation or SA offload disable, the packets will be sent out through raw socket by IPS instead of Nturbo, since the software encryption is needed in this case.

### CLI Changes:

Previously, NTurbo could only be enabled or disabled globally. The setting of np-acceleration has been added to the firewall policy context instead of just the global context.

Add: Added a CLI command in the firewall policy to enable/disable NTurbo acceleration.

```
config firewall policy
edit 1
set np-acceleration [enable|disable]
end
```

When IPS is enabled for VPN IPsec traffic, the data can be accelerated by NTurbo now.

## Toggling SNAT in Central SNAT policies (434981)

The central NAT feature is not enabled by default. When `central-nat` is enabled, `nat` option under IPv4 policies is skipped and SNAT must be done via `central-snat-map`.

- Info messages and redirection links have been added to IPv4 policy list and dialog to indicate the above
- If NGFW mode is policy-based, then it is assumed that central-nat (specifically SNAT) is enabled implicitly
- The option to toggle NAT in central-snat-map policies has been added (previously it was only shown in NGFW policy-based mode).
- In central-snat policy dialog, the port-mapping fields for the original port have been updated to accept ranges.
- Nat will be skipped in firewall policy if per vdom central nat is enabled.

### Example scenarios to show changes in how CLI treats central-nat

**Change: make nat available regardless of NGFW mode.**

```
config firewall central-snat-map
edit 1
set orig-addr "192-86-1-86"
set srcintf "port23"
set dst-addr "192-96-1-96"
set dstintf "port22"
set nat-ippool "pool1"
set protocol 17
set orig-port 2896-2897
set nat enable
end
```

**Change: hide nat-port if nat-ippool is not set or NAT is disabled.**

```
config firewall central-snat-map
edit 1
```

```

set orig-addr "192-86-1-86"
set srcintf "port23"
set dst-addr "192-96-1-96"
set dstintf "port22"
set nat-ippool "pool1"
set protocol 17
set orig-port 2896-2897
set nat disable
end

```

### Change:change orig-port to accept range

```

config firewall central-snat-map
edit 1
set orig-addr "192-86-1-86"
set srcintf "port23"
set dst-addr "192-96-1-96"
set dstintf "port22"
set nat-ippool "pool1"
set protocol 17
set orig-port 2896-2897 (help text changed to: Original port or port range).
set nat-port 35804-35805
end

```

### Improved wildcard support for firewall fqdn (444646)

The following wildcard character instances are now supported in wildcard FQDN addresses:

- "?" character
- "\*" character in the middle of a phrase
- The "?\*" combination

### Policy Matching based on Referrer Headers and Query Strings (446257)

Web proxy policies support creating web proxy addresses to match referrer headers and query strings.

#### Matching referrer headers

For example, to create a web proxy address to match the referrer header to block access to the following YouTube URL <http://youtube.com/user/test321>. The http request will have the following format:

```

GET /user/test321 HTTP/1.1
Host: www.youtube.com
User-Agent: curl/7.52.1
Accept: */*

```

Create the following web proxy addresses to match this page:

```

config firewall proxy-address
edit youtube
set type host-regex
set host-regex ".*youtube.com"
next
edit test321
set host "youtube"
set path "/user/test321"
set referrer enable

```

end

Then create two proxy policies, one that allows access to all traffic and a second one that blocks access to the page that matches the referrer header:

```
config firewall proxy-policy
edit 1
    set uuid 92273e4e-8c53-51e7-a7bd-f26e6e15fc98
    set proxy explicit-web
    set dstintf "wan2"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy-connect"
    set action accept
    set schedule "always"
    set utm-status enable
    set profile-protocol-options "test"
    set ssl-ssh-profile "test"
next
edit 2
    set uuid d35ad06a-8c53-51e7-8511-17200f682a4a
    set proxy explicit-web
    set dstintf "wan2"
    set srcaddr "all"
    set dstaddr "test321"
    set service "webproxy"
    set action accept
    set schedule "always"
    set utm-status enable
    set av-profile "default"
    set profile-protocol-options "test"
    set ssl-ssh-profile "test"
end
```

### Matching query strings

To match the video with URL `youtube.com/watch?v=XXXXXXXXXX`, (where `XXXXXXXXXX` is an example YouTube query string) you need to match an HTTP request with the following format:

```
GET /user/watch?v=GLCHldlwQsg HTTP/1.1
Host: www.youtube.com
User-Agent: curl/7.52.1
Accept: */*
```

Create the following web proxy addresses to match this video or query string:

```
config firewall proxy-address
edit "youtube"
    set uuid 4ad63880-971e-51e7-7b2e-c69423ac6314
    set type host-regex
    set host-regex ".*youtube.com"
next
edit "query-string"
    set uuid 7687a8c0-9727-51e7-5063-05edda03abbf
    set host "youtube"
    set path "/watch"
    set query "v=XXXXXXXXXX"
end
```

Then create two proxy policies, one that allows access to all traffic and a second one that blocks access to the page that matches the query string

```
config firewall proxy-policy
edit 1
set uuid 92273e4e-8c53-51e7-a7bd-f26e6e15fc98
set proxy explicit-web
set dstintf "wan2"
set srcaddr "all"
set dstaddr "all"
set service "webproxy-connect"
set action accept
set schedule "always"
set utm-status enable
set profile-protocol-options "test"
set ssl-ssh-profile "test"
next
edit 2
set uuid d35ad06a-8c53-51e7-8511-17200f682a4a
set proxy explicit-web
set dstintf "wan2"
set srcaddr "all"
set dstaddr "query-string"
set service "webproxy"
set action accept
set schedule "always"
set utm-status enable
set av-profile "default"
set profile-protocol-options "test"
set ssl-ssh-profile "test"
next
end
```

## New Firewall Features in 5.6.1

### Improvement to NAT column in Policy List Display (305575)

The NAT column in the listing of Policy can provide more information than before.

Previously the field for the policy in the column only showed whether NAT was **Enabled** or **Disabled**.

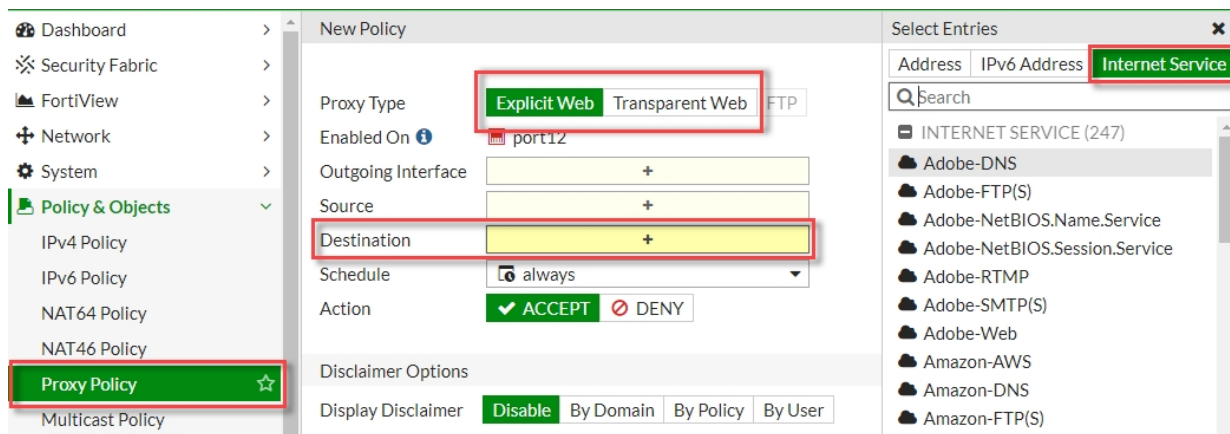

With the new improvements, not only does the field show the name of the Dynamic Pool, if one is being used, but the tool-tip feature is engaged if you hover the cursor over the icon in the field and provides even more specific information.

### GUI support for adding Internet-services to proxy-policies (405509)

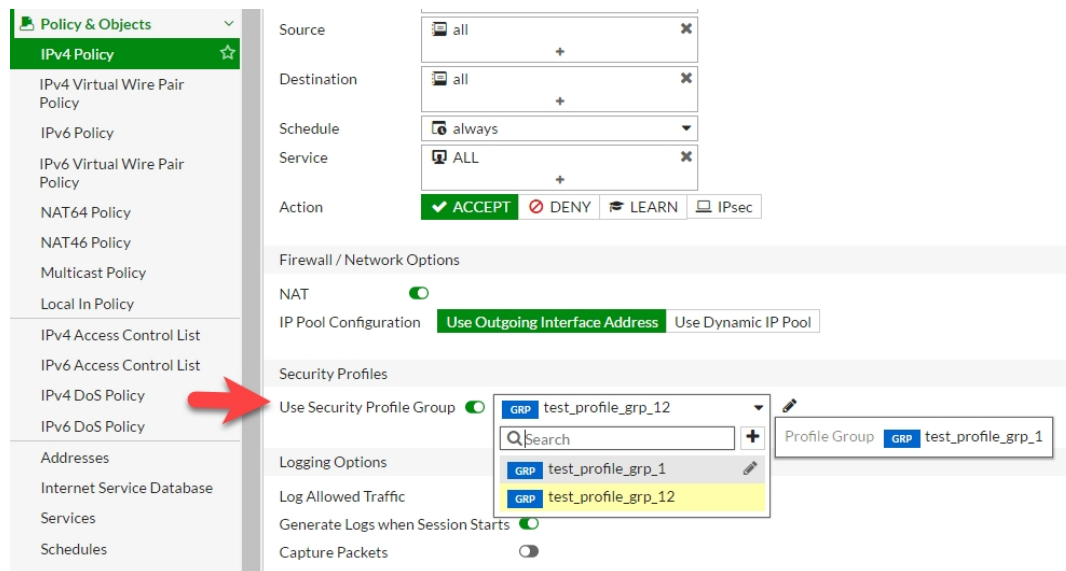

There is now GUI support for the configuration of adding Internet services to proxy policies. When choosing a destination address for a Proxy Policy, the Internet Service tab is visible and the listed objects can be selected.

By choosing an **Internet Service** object as the **Destination**, this sets `internet-service` to enable and specifying either an **Address** or **IPv6 Address** object will set `internet-service` to disable.

### Inline editing of profile groups on policy (409485)

There can now be editing to the profile groups within the policy list display window. Before, you had to go into the edit window of the policy, such as in the image below:

However, now the editing can be done from the list display of policies and clicking on the GRP icon. Right clicking on the icon will slide a window out from the left and left clicking will give you a drop-down menu.

### Rename "action" to "nat" in firewall.central-snat-map (412427)

The `action` field option in the context of `firewall central-snat-map` in the CLI was considered by some to be a little ambiguous, so it has been renamed to `nat`, an option that can either be enabled or disabled.

### Explicit proxy supports session-based Kerberos authentication (0437054)

- Explicit proxy supports session-based Kerberos authentication
- Transparent proxy will create an anonymous user if the attempt to create a NTLM connection fails.
- When FSSO authentication fails for the explicit FTP proxy, the FortiGate responds with the error message "match policy failed".

## New Firewall Features in 5.6.0

### Optimization of the firewall Service cache (355819)

In order to improve the efficiency and performance of the firewall Service cache, the following improvements have been made:

- The logic behind the structure of the cache has been simplified. Instead of storing ranges of port numbers, we store each individual port number in the cache
- Separate caches are created for each VDOM so that cache searches are faster.
- The performance of more frequently used cases has been increased
- Hash tables are used to improve the performance of complex cases. These could include such instances as:
  - service names tied to specific IP Ranges
  - redefinition (one port number with multiple service names)

### **New CLI option to prevent packet order problems for sessions offloaded to NP4 or NP6 (365497)**

In order to prevent the issue of a packet, on FortiGate processing a heavy load of traffic, from being processed out of order, a new setting has been added to better control the timing of pushing the packets being sent to NP units.

The new option, `delay-tcp-npc-session`, has been added into the context of config firewall policy within the CLI

```
config firewall policy
  edit <Integer for policy ID>
    set delay-tcp-npc-session
  end
```

Policy may not be available on units not using NP units.

### **GUI changes to Central NAT (371516)**

The Central NAT configuration interface prevents the accidental occurrence of being able to select “all” and “none” as two objects for the same field. It only allows the selecting of a single IP pool, though it is still possible to select multiple IP pools within the CLI.

### **Max value for Firewall User authentication changed (378085)**

Previously, the maximum time that a member of a firewall user group could remain authenticated without any activity was 24 hours (1440 minutes). The maximum value for this setting has been changed to 72 hours (4320 minutes). This allow someone to log in but not be kicked off the system due to inactivity over the course of a weekend.

The syntax in the CLI for configuring this setting is:

```
config user group
  edit <name of user group>
    set authtimeout 4320
  end
```

### **Changes to default SSL inspection configuration (380736)**

SSL is such a big part of normal traffic that SSL certificate inspection is no longer disabled by default. SSL inspection is now mandatory in firewall policies whenever a policy includes a security profile. The default setting is the Certificate Inspection level. As a result there have been a few changes within the CLI and the GUI.

#### **CLI**

The setting `SSL-SSH-Profile`, is a required option, with the default value being “certificate-inspection”, when it is applicable in the following tables:

- firewall.profile-group
- firewall.policy
- firewall.policy6,
- firewall.proxy-policy

The following default profiles are read-only:

- certificate-inspection
- deep-ssl-inspection

## GUI

### IPv4/IPv6 Policy and Explicit Proxy Policy edit window

- The configuration and display set up for SSL/SSH Inspection is now similar to "profile-protocol-option" option
- The disable/enable toggle button is no longer available for the Profile Protocol Option
- The default profile is set to "certificate-inspection"

### IPv4/IPv6 Policy, Explicit Proxy Policy list page

- There is validation for SSL-SSH-Profile when configuring UTM profiles

### SSL/SSH Inspection list page

- There is no delete menu on GUI for default ssl profiles
- The "Edit" menu has been changed to "View" for default SSL profiles
- The default SSL profile entries are considered an implicit class and are grayed out

### SSL/SSH Inspection edit window

- The only input for default SSL profiles is now download/view trusted certificate links
- To return to the List page from default SSL profiles, the name of the button is now "Return"

### Profile Group edit window

- There is no check box for SSL-SSH-Profile. It is always required.

## Name change conventions due to upgrade

Starting in 5.6, the profiles "certificate-inspection" and "deep-inspection" are set up by the firmware as default read-only profiles. If you have profiles with these names that were configured in a previous version of FortiOS, rather than overwrite the firmware's default profile, profiles with these names will be upgraded to reflect the configuration conventions of the new firmware but the profile names will be changed by adding a prefix of "\_upg\_".

## Add firewall policy comment field content to log messages (387865)

There has been a need by some customer to have some information in the logs that includes specific information about the traffic that produced the log. The rather elegant solution is that when the log-policy-comment option is enabled, the comment field from the policy will be included in the log. In order to make the logs more useful regarding the traffic just include a customized comment in the policy and enable this setting.

## Syntax

```
config system settings
    set log-policy-comment [enable | disable]
```

```
end
```

- This setting is for all traffic and security logs.
- It can be select on a per VDOM basis

### Learning mode changes profile type to single (387999)

The Learning mode does not function properly when it is applied to a policy that has a UTM profile group applied to it. The logging that should be taking place from the Learning Mode profiles does not occur as intended, and the

Automatically switching the profile type to single on a policy with Learning mode enabled prevents it from being affected by the UTM policy groups.

### MAC address authentication in firewall policies and captive portals (391739)

When enabled, a MAC authentication request will be sent to `fnbamd` on any traffic. If the authentication receives a positive response, login becomes available. If the response is negative the normal authentication process takes over.

## CLI

### New option in the firewall policy setting

```
config firewall policy
  edit <policy ID>
    set radius-mac-auth-bypass [enable |disable]
  end
```

### New option in the interface setting

```
config system interface
  edit <interface>
    set security-mode captive-portal
    set security-mac-auth-bypass
  end
```

### Display resolved IP addresses for FQDN in policy list (393927)

If a FQDN address object is used in a policy, hovering the cursor over the icon for that object will show a tool tip that lists the parameters of the address object. This tool tip now includes the IP address that the FQDN resolves to.

### Added comment for acl-policy, interface-policy and DoS-policy (396569)

A comment field has been added to the following policy types:

- `acl-policy`
- `interface-policy`
- `DoS-policy`

Comments of up to 1023 characters can be added through the CLI.

## Examples:

### DoS policy

```
config firewall DoS-policy
  edit 1
    set comment "you can put a comment here(Max 1023)."
    set interface "internal"
    set srcaddr "all"
    set dstaddr "all"
    set service "ALL"
    config anomaly
      edit "tcp_syn_flood"
        set threshold 2000
      next
    end
  end
```

### Interface policy

```
config firewall interface-policy
  edit 1
    set comment "you can put a comment here(max 1023)."
    set interface "dmz2"
    set srcaddr "all"
    set dstaddr "all"
    set service "ALL"
  end
```

### Firewall ACL

```
config firewall acl
  edit 1
    set status disable
    set comment "you can put a comment here(max 1023)."
    set interface "port5"
    set srcaddr "all"
    set dstaddr "all"
    set service "ALL"
  end
```

## Internet service settings moved to more logical place in CLI (397029)

The following settings have moved from the application context of the CLI to the firewall context:

- internet-service
- internet-service-custom

### Example of **internet-service**

```
config firewall internet-service 1245324
  set name "Fortinet-FortiGuard"
  set reputation 5
  set icon-id 140
  set offset 1602565
  config entry
    edit 1
      set protocol 6
```

```

        set port 443
        set ip-range-number 27
        set ip-number 80
        next
    edit 2
        set protocol 6
        set port 8890
        set ip-range-number 27
        set ip-number 80
        next
    edit 3
        set protocol 17
        set port 53
        set ip-range-number 18
        set ip-number 31
        next
    edit 4
        set protocol 17
        set port 8888
        set ip-range-number 18
        set ip-number 31
        next
end

```

#### Example of `internet-service-custom`

```

config firewall internet-service-custom
    edit "custom1"
        set comment "custom1"
        config entry
            edit 1
                set protocol 6
                config port-range
                    edit 1
                        set start-port 30
                        set end-port 33
                        next
                    end
                set dst "google-drive" "icloud"
                next
            end
        next
    end
end

```

#### Example of `get` command:

```

get firewall internet-service-summary
Version: 00004.00002
Timestamp: 201611291203
Number of Entries: 1349

```

### Certificate key size selection (397883)

FortiOS will now support different SSL certificate key lengths from the HTTPS server. FortiOS will select a key size from the two options of 1024 and 2048, to match the key size (as close as possible, rounding up) on the

HTTPS server. If the size of the key from the server is 512 or 1024 the proxy will select a 1024 key size. If the key size from the servers is over 1024, the proxy will select a key size of 2048.

### CLI changes:

In `ssl-ssh-profile` remove:

- `certname-rsa`
- `certname-dsa`
- `certname-ecdsa`

In `vpn certificate` setting, add the following options :

- `certname-rsa1024`
- `certname-rsa2048`
- `certname-dsa1024`
- `certname-dsa2048`
- `certname-ecdsa256`
- `certname-ecdsa384`

### AWS API integration for dynamic firewall address object (400265)

Some new settings have been added to the CLI that will support instance information being retrieved directly from the AWS server. The IP address of a newly launched instance can be automatically added to a certain firewall address group if it meets specific requirements. The new address type is: `ADDR_TYPE_AWS`

### New CLI configuration settings:

#### The AWS settings

```
config aws
  set access-key
  set secret-key
  set region
  set vpc-id
  set update-interval
```

- `access-key` - AWS access key.
- `secret-key` - AWS secret key.
- `region` - AWS region name.
- `vpc-id` - AWS VPC ID.
- `update-interval` - AWS service update interval (60 - 600 sec, default = 60).

#### The AWS address:

```
config firewall address
  edit <address name>
    set type aws
    set filter <filter values>
```

The filter can be a combination of any number of conditions, as long as the total length of filter is less than 2048 bytes. The syntax for the filter is:

```
<key1=value1> [& <key2=value2>] [| <key3=value3>]
```

For each condition, it includes a key and value, the supported keys are:

1. `instanceId`, (e.g. `instanceId=i-12345678`)
2. `instanceType`, (e.g. `instanceType=t2.micro`)
3. `imageId`, (e.g. `imageId=ami-123456`)
4. `keyName`, (e.g. `keyName=aws-key-name`)
5. `architecture`, (e.g. `architecture=x86`)
6. `subnetId`, (e.g. `subnetId=sub-123456`)
7. `placement.availabilityzone`, (e.g. `placement.availabilityzone=us-east-1a`)
8. `placement.groupname`, (e.g. `placement.groupname=group-name`)
9. `placement.tenancy`, (e.g. `placement.tenancy=tenancy-name`)
10. `privateDnsName`, (e.g. `privateDnsName=ip-172-31-10-211.us-west-2.compute.internal`)
11. `publicDnsName`, (e.g. `publicDnsName=ec2-54-202-168-254.us-west-2.compute.amazonaws.com`)
12. AWS instance tag, each tag includes a key and value, the format of tag set is: `tag.Name=Value`, maximum of 8 tags are supported.

### Internet service configuration (405518)

To make the CLI configuration of Internet service configuration more intuitive, the settings for Internet service in Explicit Web proxy are closer to those in the Firewall police. An Internet service enable switch has been added to the Explicit Web proxy with the same text description as the Firewall policy.

CLI:

The relevant options in the firewall policy are:

```
config firewall policy
  edit 1
    set internet-service enable
    set internet-service-id 327681 1572864 917519 393225 1572888 1572877 917505
  next
end
```

The Explicit Web proxy is now has these options:

```
config firewall proxy-policy
  edit 1
    set uuid f68e0426-dda8-51e6-ac04-37fc3f92cadf
    set proxy explicit-web
    set dstintf "port9"
    set srcaddr "all"
    set internet-service 2686980
    set action accept
    set schedule "always"
    set logtraffic all
  next
end
```

## Changes to SSL abbreviate handshake (407544)

The SSL handshake process has changed to make troubleshooting easier.

- In order to better identify which clients have caused SSL errors, the WAD SSL log will use the original source address rather than the source address of packets.
- The return value of `wad_ssl_set_cipher` is checked.
- The `wad_ssl_session_match` has been removed because it will add the connection into bypass cache and bypass further inspection.
- DSA and ECDSA certificates are filtered for `admin-server-cert`
- `cert-inspect` is reset after a WAD match to a Layer 7 policy
- An option to disable the use of SSL abbreviate handshake has been added

## CLI addition

```
config firewall ssl setting
    set abbreviate-handshake [enable|disable]
```

## NGFW mode in the VDOM - NAT & SSL Inspection considerations (407547)

Due to how the NGFW Policy mode works, it can get complicated in the two areas of NAT and SSL Deep Inspection. To match an application against a policy, some traffic has to pass through the FortiGate in order to be properly identified. Once that happens may end up getting mapped to a different policy, where the new policy will be appropriately enforced.

### NAT

In the case of NAT being used, the first policy that is triggered to identify the traffic might require NAT enabled for it to work correctly. i.e., without NAT enabled it may never be identified, and thus not fall through. Let's use a very simple example:

Policy 1: Block Youtube

Policy 2: Allow everything else (with NAT enabled)

Any new session established will never be identified immediately as Youtube, so it'll match policy #1 and let some traffic go to try and identify it. Without NAT enabled to the Internet, the session will never be setup and thus stuck here.

### Solution:

- NAT for NGFW policies must be done via Central SNAT Map
- Central SNAT Map entries now have options for 'srcintf', 'dstintf' and 'action'.
- If no IP-pools are specified in the Central SNAT entry, then the outgoing interface address will be used.
- NGFW policies now must use a single default ssl-ssh-profile. The default ssl-ssh-profile can be configured under the system settings table.

### SSL

In the case of SSL inspection, the issue is a bit simpler. For each policy there are 3 choices:

1. No SSL,
2. Certificate Only
3. Deep Inspection.

For 1. and 2. there is no conflict and the user could enable them inter-changeably and allow policy fallthrough.

The issue happens when:

- The first policy matched, uses **Certificate Only**
- After the application is detected, it re-maps the session to a new policy which has **Deep Inspection** enabled

This switching of behavior is the main cause of the issue.

#### Solution:

- Multiple SSL profiles have been replaced with a single page of settings
- The user can setup exemptions for destination web category, source IP or etc.

## CLI

### Changes

```
config system settings
  set inspection-mode flow
  set policy-mode [standard | ngfw]
```

Has been changed to:

```
config system settings
  set inspection-mode flow
  set ngfw-mode [profile-based | policy-based]
```

- ngfw-mode - Next Generation Firewall mode.
- profile-based - Application and web-filtering is configured using profiles applied to policy entries.
- policy-based - Application and web-filtering is configured as policy match conditions.

### Additions

#### Setting the vdom default ssl-ssh-profile

```
config system settings
  set inspection-mode flow
  set ngfw-mode policy-based
  set ssl-ssh-profile <profile>
```

ssl-ssh-profile - VDOM SSL SSH profile.

#### Setting srcintf, dstintf, action on the central-snat policy

```
config firewall central-snat-map
  edit <id>
    set srcintf <names or any>
    set dstintf <names or any>
    set action (permit | deny)
```

- srcintf - Source interface name.
- dstintf - Destination interface name.

- `action` - Action of central SNAT policy.

## GUI

### System settings, VDOM settings list/dialog:

- A field has been added to show the default `ssl-ssh-profile`

### IPv4/v6 Policy list and dialogs:

- In NGFW policy-based mode, there are added tool tips under NAT columns/fields to indicate that NAT must be configured via Central SNAT Map. Additionally, links to redirect to Central SNAT list were added.
- Default `ssl-ssh-profile` is shown in the policy list and dialog for any policies doing NGFW (`application, application-categories, url-categories`) or UTM (`av-profile etc.`) inspection.
  - Default `ssl-ssh-profile` is disabled from editing in policy list dialog

### Central SNAT Policy list and dialogs:

- In both `profile-based` & `policy-based ngfw-mode`, fields for `srcintf`, `dstintf` were added to Central SNAT policies entries.
- In `policy-based` mode only, a toggle-switch for **NAT Action** was added in Central SNAT policy dialog. The action is also configurable from the **Action** column in Central SNAT policy list.

### SSL/SSH Inspection list:

- In policy-based mode only, the navigation bar link to **SSL/SSH Inspection** redirects to the profiles list
- In policy-based mode only, the **SSL/SSH Inspection** list table indicates which profile is the current VDOM default. Additionally, options are provided in the list menu and context menu to change the current VDOM default.

## Support HTTP policy for flow-based inspection (411666)

It is possible to implement an HTTP-policy in a VDOM that is using the Flow-based inspection mode. Enabling the HTTP-policy causes the traffic to be redirected to WAD so that the traffic can be properly matched and processed.

## Support for CA chain downloading to improve certificate verification (369270)

During certificate verification, if the certificate chain is not complete and CA issuer information exists in the certificate, FortiOS attempts to download intermediate/root CAs from the HTTP server and attempts to perform chain verification. The downloaded CAs are saved in a cache (max 256) to be re-used for future certificate validation. CAs are removed from the cache if they are inactive or not needed for more than 1 hour.

CA chain downloading is used to improve verification results for certificates that are difficult to verify. The CAs are kept in the cache to improve performance.

## New WAN Optimization Features in 5.6

### WAN Optimization GUI changes (283422)

Improvements have been made to the WAN Optimization **Profiles** and **Authentication Group** pages.

## New Proxy Features in 5.6

### Explicit proxy supports multiple incoming ports and port ranges (402775, 398687)

Explicit proxy can now be configured to listen on multiple ports on the same IP as well as listen for HTTP and HTTPS on those same (or different) ports.

Define the IP ranges using a hyphen (-). As shown below, `port_high` is not necessary to specify if `port_low` is equal to `port_high`.

#### CLI syntax

```
config web-proxy explicit
    set http-incoming-port <port_low> [-<port_high>]
end
```

### Explicit proxy supports IP pools (402221)

Added a new command, `poolname`, to `config firewall proxy-policy`. When setting the IP pool name with this command, the outgoing IP will be selected.

#### CLI syntax

```
config firewall proxy-policy
    edit <example>
        set poolname <name>
    end
```

### Option to remove unsupported encoding from HTTP headers (392908)

Added a new command to `config web-proxy profile` that, when enabled, allows the FortiGate to strip out unsupported encoding from request headers, and correctly block banned words. This is to resolve issues when attempting to successfully block content using Google Chrome.

#### CLI syntax:

```
config web-proxy profile
    edit <example>
        set strip-encoding {enable | disable}
    end
```

### New authentication process for explicit web proxying (386474, 404355)

While in Proxy inspection mode, explicit proxy options can be set under **Network > Explicit Proxy**. These settings will affect what options are available for creating proxy policies under **Policy & Objects > Proxy Policy**. From here you may create new policies with **Proxy Type** set to either **Explicit Web**, **Transparent Web**, or **FTP**.

Authentication will be triggered differently when configuring a transparent HTTP policy. Before such a policy can be configured, you must enable **HTTP Policy Redirect** under **Security Profiles > Proxy Options**.

### Added Internet services to explicit proxy policies (386182)

Added two new commands to `config firewall proxy-policy`. FortiOS can use the Internet Service Database (introduced in 5.4.1) as the web-proxy policy matching factor.

#### CLI syntax:

```
config firewall proxy-policy
  edit <example>
    set internet-service <application-id>
    set internet-service-custom <application-name>
```

### Virtual WAN link in an explicit proxy firewall policy (385849, 396780)

Virtual WAN link (VWL) interfaces may now be set as the destination interface in an explicit proxy policy, routing traffic properly using basic virtual WAN link load balance settings. This is now configurable through both the CLI under `firewall proxy-policy` and the GUI.

### Added application ID and category setting on the explicit proxy enabled service (379330)

This feature introduces support for application ID/category in the service of explicit proxy as one policy selection factor. The intent is to identify the application type based on the HTTP request with IPS application type detection function. It is similar to the current firewall explicit address, but it is implemented as a service type, and you can select the application ID/ category to define explicit service. Of course, now it must be an HTTP-based application.

#### CLI syntax

```
config firewall service custom
  edit "name"
    set app-service-type [disable|app-id|app-category]
  next
end
```

### Explicit Proxy - populate pac-file-url in transparent mode (373977)

You can now use `manageip` to populate `pac-file-url` in transparent opmode. Previously, in the CLI, when displaying `pac-file-url`, the code only tries to get interface IP to populate `pac-file-url`.

#### CLI syntax

```
config vdom
  edit root
    config system settings
      set opmode transparent
      set manageip 192.168.0.34/24
    end
    config web-proxy explicit
      set pac-file-server-status enable
      get pac-file-url [url.pac]
    end
```

### SSL deep inspection OCSP support for Explicit Proxy (365843)

OCSP support for SSL deep inspection added for Explicit Proxy.

**CLI syntax**

```
config vpn certificate setting
  set ssl-ocsp-status [enable|disable]
  set ssl-ocsp-option [certificate|server]
end
```

**Timed out authentication requests are now logged (357098)****CLI syntax**

```
config web-proxy explicit
  set trace-auth-no-rsp [enable|disable]
end
```

## Firewall concepts

There are a number of foundational concepts that are necessary to have a grasp of before delving into the details of how the FortiGate firewall works. Some of these concepts are consistent throughout the firewall industry and some of them are specific to more advanced firewalls such as the FortiGate. Having a solid grasp of these ideas and terms can give you a better idea of what your FortiGate firewall is capable of and how it will be able to fit within your networks architecture.

This chapter describes the following firewall concepts:

- [What is a Firewall?](#)
- [FortiGate Modes](#)
- [How Packets are handled by FortiOS](#)
- [Interfaces and Zones](#)

### What is a Firewall?

The term firewall originally referred to a wall intended to confine a fire or potential fire within a building. Later uses refer to similar structures, such as the metal sheet separating the engine compartment of a vehicle or aircraft from the passenger compartment.

A firewall can either be software-based or hardware-based and is used to help keep a network secure. Its primary objective is to control the incoming and outgoing network traffic by analyzing the data packets and determining whether it should be allowed through or not, based on a predetermined rule set. A network's firewall builds a

bridge between an internal network that is assumed to be secure and trusted, and another network, usually an external (inter)network, such as the Internet, that is not assumed to be secure and trusted.

## Network Layer or Packet Filter Firewalls

### Stateless Firewalls

Stateless firewalls are the oldest form of these firewalls. They are faster and simple in design requiring less memory because they process each packet individually and don't require the resources necessary to hold onto packets like stateful firewalls. Stateful firewalls inspect each packet individually and check to see if it matches a predetermined set of rules. According to the matching rule the packet is either be allowed, dropped or rejected. In the case of a rejection an error message is sent to the source of the traffic. Each packet is inspected in isolation and information is only gathered from the packet itself. Simply put, if the packets were not specifically allowed according to the list of rules held by the firewall they were not getting through.

### Stateful Firewalls

Stateful firewalls retain packets in memory so that they can maintain context about active sessions and make judgments about the state of an incoming packet's connection. This enables Stateful firewalls to determine if a packet is the start of a new connection, a part of an existing connection, or not part of any connection. If a packet is part of an existing connection based on comparison with the firewall's state table, it will be allowed to pass without further processing. If a packet does not match an existing connection, it will be evaluated according to the rules set for new connections. Predetermined rules are used in the same way as a stateless firewall but they can now work with the additional criteria of the state of the connection to the firewall.

---

Best Practices Tip for improving performance:

Blocking the packets in a denied session can take more cpu processing resources than passing the traffic through. By putting denied sessions in the session table, they can be kept track of in the same way that allowed session are so that the FortiGate unit does not have to redetermine whether or not to deny all of the packets of a session individually. If the session is denied all packets of that session are also denied.

In order to configure this you will need to use 2 CLI commands

```
config system setting
    set ses-denied-traffic enable
    set block-session-timer <integer 1 - 300> (this determines in
seconds how long, in seconds, the session is kept in the table)
end
```

---

## Application Layer Firewalls

Application layer filtering is yet another approach and as the name implies it works primarily on the Application Layer of the OSI Model.

Application Layer Firewalls actually, for lack of a better term, understand certain applications and protocols. Examples would be FTP, DNS and HTTP. This form of filtration is able to check to see if the packets are actually behaving incorrectly or if the packets have been incorrectly formatted for the protocol that is indicated. This process also allows for the use of deep packet inspection and the sharing of functionality with Intrusion Prevention Systems (IPS).

Application-layer firewalls work on the application level of the TCP/IP stack (i.e., all browser traffic, or all telnet or ftp traffic), and may intercept all packets traveling to or from an application. They block other packets (usually dropping them without acknowledgment to the sender). Application firewalls work much like a packet filter but application filters apply filtering rules (allow/block) on a per process basis instead of filtering connections on a per port basis.

On inspecting all packets for improper content, firewalls can restrict or prevent outright the spread of networked computer worms and trojans. The additional inspection criteria can add extra latency to the forwarding of packets to their destination.

## Proxy Servers

A proxy server is an appliance or application that acts as an intermediary for communicating between computers. A computer has a request for information. The packets are sent to the designated resource but before they can get there they are blocked by the proxy server saying that it will take the request and pass it on. The Proxy Server processes the request and if it is valid it passes onto the designated computer. The designated computer gets the packet and processes the request, sending the answer back to the proxy server. The proxy server sends the information back to the originating computer. It's all a little like a situation with two people who refuse to talk directly with each other using someone else to take messages back and forth.

From a security stand point a Proxy Server can serve a few purposes:

- Protects the anonymity of the originating computer
- The two computers never deal directly with each other
- Packets that are not configured to be forwarded are dropped before reaching the destination computer.
- If malicious code is sent it will affect the Proxy server with out affecting the originating or sending computer.

Proxies can perform a number of roles including:

- Content Filtering
- Caching
- DNS proxy
- Bypassing Filters and Censorship
- Logging and eavesdropping
- Gateways to private networks
- Accessing service anonymously

## UTM/ NGFW

Unified Threat Management and Next Generation Firewall are terms originally coined by market research firms and refer to the concept of a comprehensive security solution provided in a single package. It is basically combining of what used to be accomplished by a number of different security technologies all under a single umbrella or in this case, a single device. On the FortiGate firewall this is achieved by the use of Security Profiles and optimized hardware.

In effect it is going from a previous style of firewall that included among its features:

- Gateway Network Firewall
- Routing
- VPN

To a more complete system that includes:

- Gateway Network Firewall
- Routing
- VPN
- Traffic Optimization
- Proxy Services
- Content Filtering
- Application Control
- Intrusion Protection
- Denial of Service Attack Protection
- Anti-virus
- Anti-spam
- Data Leak Prevention
- Endpoint Control of Security Applications
- Load Balancing
- WiFi Access Management
- Authentication Integration into Gateway Security
- Logging
- Reporting

### Advantages of using Security Profiles

- Avoidance of multiple installations.
- Hardware requirements are fewer.
- Fewer hardware maintenance requirements.
- Less space required.
- Compatibility - multiple installations of products increase the probability of incompatibility between systems.
- Easier support and management.
- There is only one product to learn therefore a reduced requirement of technical knowledge.
- Only a single vendor so there are fewer support contracts and Service Level Agreements.
- Easier to incorporated into existing security architecture.
- Plug and play architecture.
- Web based GUI for administration.

## FortiGate Modes

The FortiGate unit has a choice of modes that it can be used in, either NAT/Route mode or Transparent mode. The FortiGate unit is able to operate as a firewall in both modes, but some of its features are limited in Transparent mode. It is always best to choose which mode you are going to be using at the beginning of the set up. Once you start configuring the device, if you want to change the mode you are going to lose all configuration settings in the change process.

### NAT/Route Mode

NAT/Route mode is the most commonly used mode by a significant margin and is thus the default setting on the device. As the name implies the function of NAT is commonly used in this mode and is easily configured but there

is no requirement to use NAT. The FortiGate unit performs network address translation before IP packets are sent to the destination network.

These are some of the characteristics of NAT/Route mode:

- Typically used when the FortiGate unit is a gateway between private and public networks.
- Can act as a router between multiple networks within a network infrastructure.
- When used, the FortiGate unit is visible to the networks that it is connected to.
- Each logical interface is on a distinct subnet.
- Each Interface needs to be assigned a valid IP address for the subnet that it is connected to it.

## Transparent Mode

Transparent mode is so named because the device is effectively transparent in that it does not appear on the network in the way that other network devices show as a nodes in the path of network traffic. Transparent mode is typically used to apply the FortiOS features such as Security Profiles etc. on a private network where the FortiGate unit will be behind an existing firewall or router.

These are some of the characteristics of Transparent mode:

- The FortiGate unit is invisible to the network.
- All of its interfaces are on the same subnet and share the same IP address.
- The FortiGate unit uses a Management IP address for the purposes of Administration.
- Still able to use NAT to a degree, but the configuration is less straightforward

In Transparent mode, you can also perform NAT by creating a security policy or policies that translates the source addresses of packets passing through the FortiGate unit as well as virtual IP addresses and/or IP pools.

## How Packets are handled by FortiOS

To give you idea of what happens to a packet as it makes its way through the FortiGate unit here is a brief overview. This particular trip of the packet is starting on the Internet side of the FortiGate firewall and ends with the packet exiting to the Internal network. An outbound trip would be similar. At any point in the path if the packet is going through what would be considered a filtering process and if fails the filter check the packet is dropped and does not continue any further down the path.

This information is covered in more detail in other in the Troubleshooting chapter of the FortiOS Handbook in the Life of a Packet section.

The incoming packet arrives at the external interface. This process of entering the device is referred to as **ingress**.

### Step #1 - Ingress

1. Denial of Service Sensor
2. IP integrity header checking
3. IPsec connection check
4. Destination NAT
5. Routing

**Step #2 - Stateful Inspection Engine**

1. Session Helpers
2. Management Traffic
3. SSL VPN
4. User Authentication
5. Traffic Shaping
6. Session Tracking
7. Policy lookup

**Step #3 - Security Profiles scanning process**

1. Flow-based Inspection Engine
2. IPS
3. Application Control
4. Data Leak Prevention
5. Email Filter
6. Web Filter
7. Anti-virus
8. Proxy-based Inspection Engine
9. VoIP Inspection
10. Data Leak Prevention
11. Email Filter
12. Web Filter
13. Anti-virus
14. ICAP

**Step #4 - Egress**

1. IPsec
2. Source NAT
3. Routing

**Interfaces and Zones**

A Firewall is a gateway device that may be the nexus point for more than 2 networks. The interface that the traffic is coming in on and should be going out on is a fundamental concern for the purposes of routing as well as security. Routing, policies and addresses are all associated with interfaces. The interface is essentially the connection point of a subnet to the FortiGate unit and once connected can be connected to other subnets.

The following types of interfaces are found on a FortiGate:

- Interface , this can refer to a physical or virtual interface
- Zone
- Virtual Wired Pair

## Interfaces

Physical interfaces or not the only ones that need to be considered. There are also virtual interfaces that can be applied to security policies. VLANs are one such virtual interface. Interfaces if certain VPN tunnels are another.

Policies are the foundation of the traffic control in a firewall and the Interfaces and addressing is the foundation that policies are based upon. Using the identity of the interface that the traffic connects to the FortiGate unit tells the firewall the initial direction of the traffic. The direction of the traffic is one of the determining factors in deciding how the traffic should be dealt with. You can tell that interfaces are a fundamental part of the policies because, by default, this is the criteria that the policies are sorted by.

## Zones

Zones are a mechanism that was created to help in the administration of the firewalls. If you have a FortiGate unit with a large number of ports and a large number of nodes in your network the chances are high that there is going to be some duplication of policies. Zones provide the option of logically grouping multiple virtual and physical FortiGate firewall interfaces. The zones can then be used to apply security policies to control the incoming and outgoing traffic on those interfaces. This helps to keep the administration of the firewall simple and maintain consistency.

For example you may have several floors of people and each of the port interfaces could go to a separate floor where it connects to a switch controlling a different subnet. The people may be on different subnets but in terms of security they have the same requirements. If there were 4 floors and 4 interfaces a separate policy would have to be written for each floor to be allowed out on to the Internet off the WAN1 interface. This is not too bad if that is all that is being done, but now start adding the use of more complicated policy scenarios with Security Profiles, then throw in a number of Identity based issues and then add the complication that people in that organization tend to move around in that building between floors with their notebook computers.

Each time a policy is created for each of those floors there is a chance of an inconsistency cropping up. Rather than make up an additional duplicate set of policies for each floor, a zone can be created that combines multiple interfaces. And then a single policy can be created that uses that zone as one side of the traffic connection.

You cannot add physical interfaces associated with VLANs to zones.

---

## Virtual Wire Pair

The simplified explanation is that two interfaces are set up so that whatever traffic goes through one of the pair is replicated on the other. They are most commonly used when scanning is needed on an interface without interfering with the traffic. On interface "A", everything goes through unaffected. The replicated traffic on interface "B" is sent to an analyzer of some kind and the traffic can be thoroughly scanned without worry of impacting performance.

When two physical interfaces are setup as a Virtual Wire Pair, they will have no IP addressing and are treated similar to a transparent mode VDOM. All packets accepted by one of the interfaces in a virtual wire pair can only exit the FortiGate through the other interface in the virtual wire pair and only if allowed by a virtual wire pair firewall policy. Packets arriving on other interfaces cannot be routed to the interfaces in a virtual wire pair. A FortiGate can have multiple virtual wire pairs.

You cannot add VLANs to virtual wire pairs. However, you can enable wildcard VLANs for a virtual wire pair. This means that all VLAN-tagged traffic can pass through the virtual wire pair if allowed by virtual wire pair firewall policies.

## Access Control Lists

Access Control Lists (ACLs) in the FortiOS firmware could be considered a granular or more specifically targeted blacklist. These ACLs drop IPv4 or IPv6 packets at the physical network interface before the packets are analyzed by the CPU. On a busy appliance this can really help the performance.

The ACL feature is available on FortiGates with NP6-accelerated interfaces. ACL checking is one of the first things that happens to the packet and checking is done by the NP6 processor. The result is very efficient protection that does not use CPU or memory resources.

## Incoming Interfaces

The configuration of the Access Control List allow you to specify which in interface the ACL will be applied to. There is a hardware limitation that needs to be taken into account. The ACL is a Layer 2 function and is offloaded to the ISF hardware, therefore no CPU resources are used in the processing of the ACL. It is handled by the inside switch chip which can do hardware acceleration, increasing the performance of the FortiGate. The drawback is that the ACL function is only supported on switch fabric driven interfaces. It also cannot be applied to hardware switch interfaces or their members. Ports such as WAN1 or WAN2 that are found on some models that use network cards that connect to the CPU through a PCIe bus will not support ACL.

## Addresses

Because the address portion of an entry is based on a FortiGate address object, it can be any of the address types used by the FortiGate, including address ranges. There is further granularity by specifying both the source and destination addresses. The traffic is blocked not on an either or basis of these addresses but the combination of the two, so that they both have to be correct for the traffic to be denied. Of course, if you want to block all of the traffic from a specific address all you have to do is make the destination address "all".

Because the blocking takes place at the interface based on the information in the packet header and before any processing such as NAT can take place, a slightly different approach may be required. For instance, if you are trying to protect a VIP which has an external address of x.x.x.x and is forwarded to an internal address of y.y.y.y, the destination address that should be used is x.x.x.x, because that is the address that will be in the packet's header when it hits the incoming interface.

## Services

Further granulation of the filter by which the traffic will be denied is done by specifying which service the traffic will use.

## Firewall policies

The firewall policy is the axis around which most of the other features of the FortiGate firewall revolve. A large portion of the settings in the firewall at some point will end up relating to or being associated with the firewall policies and the traffic that they govern. Any traffic going through a FortiGate unit has to be associated with a policy. These policies are essentially discrete compartmentalized sets of instructions that control the traffic flow going through the firewall. These instructions control where the traffic goes, how it's processed, if it's processed and even whether or not it's allowed to pass through the FortiGate.

When the firewall receives a connection packet, it analyzes the packet's source address, destination address, and service (by port number). It also registers the incoming interface, the outgoing interface it will need to use and the time of day. Using this information the FortiGate firewall attempts to locate a security policy that matches the packet. If it finds a policy that matches the parameters it then looks at the action for that policy. If it is **ACCEPT**

the traffic is allowed to proceed to the next step. If the Action is **DENY** or a match cannot be found the traffic is not allowed to proceed.

The 2 basic actions at the initial connection are either **ACCEPT** or **DENY**:

- If the **Action** is **ACCEPT**, the policy action permits communication sessions. There may be other packet processing instructions, such as requiring authentication to use the policy or restrictions on the source and destination of the traffic.
- If the **Action** is **DENY**, the policy action blocks communication sessions, and you can optionally log the denied traffic. If no security policy matches the traffic, the packets are dropped. A **DENY** security policy is needed when it is required to log the denied traffic, also called “violation traffic”.

There are two other Actions that can be associated with the policy:

- **LEARN** - This is a specialized variation on the **ACCEPT** action. That is set up to allow traffic but to keep traffic logs so that the administrator can go through them to learn what kind of traffic has to be dealt with.
- **IPsec** - This is an **ACCEPT** action that is specifically for IPsec VPNs.

There can also be a number of instructions associated with a FortiGate firewall in addition to the **ACCEPT** or **DENY** actions, some of which are optional. Instructions on how to process the traffic can also include such things as:

- Logging Traffic
- Authentication
- Network Address Translation or Port Address Translation
- Use Virtual IPs or IP Pools
- Caching
- Whether the source of the traffic is based on address, user, device or a combination
- Whether to treat as regular traffic or IPsec traffic
- What certificates to use
- Security profiles to apply
- Proxy Options
- Traffic Shaping

## Firewall policy parameters

As mentioned before, for traffic to flow through the FortiGate firewall there must be a policy that matches its parameters:

### Incoming Interface(s)

This is the interface or interfaces that the traffic is first connection to the FortiGate unit by. The exception being traffic that the FortiGate generates itself. This is not limited to the physical Ethernet ports found on the device. The incoming interface can also be a logical or virtual interface such as a VPN tunnel, a Virtual WAN link or a wireless interface.

### Outgoing Interface(s)

After the firewall has processed the traffic it needs to leave a port to get to its destination and this will be the interface or interfaces that the traffic leaves by. This interface, like the **Incoming Interface** is not limited to only physical interfaces.

## Source Address(es)

The addresses that a policy can receive traffic from can be wide open or tightly controlled. For a public web server that the world at large should be able to access, the best choice will be “all”. If the destination is a private web server that only the branch offices of a company should be able to access or a list of internal computers that are the only ones allowed to access an external resource then a group of preconfigured addresses is the better strategy.

Additional parameters under the Source Address, though they are not mandatory are:

- **Source User(s)**

This parameter is based on a user identity that can be from a number of authentication authorities. It will be an account or group that has been set up in advance that can be selected from the drop down menu. The exception to this is the feature that allows the importing of LDAP Users. When the feature is used, a small wizard window will appear to guide the user through the setup. The caveat is that the LDAP server object in the **User and Device > Authentication > LDAP Servers** section has to be already configured to allow the use of this import feature.

- **Source Device Type**

This parameter is for narrowing down the traffic sending devices to those that the FortiGate is familiar with. Again the contents of this parameter need to be a preconfigured object and these are defined at **User and Device > Custom Devices & Groups**. This parameter can limit the devices that can connect to this policy to those specific MAC addresses that are already known by the FortiGate and are approved for the policy.

## Destination Address(es)

In the same way that the source address may need to be limited, the destination address can be used as a traffic filter. When the traffic is destined for internal resources the specific address of the resource can be defined to better protect the other resources on the network. One of the specialized destination address options is to use a Virtual IP address. The destination address doesn't need to be internal you can define policies that are only for connecting to specific addresses on the Internet.

## Internet service(s)

In this context, an Internet service is a combination of one or more addresses and one or more services associated with a service found on the Internet such as an update service for software.

## Schedule

The time frame that is applied to the policy. This can be something as simple as a time range that the sessions are allowed to start such as between 8:00 am and 5:00 pm. Something more complex like business hours that include a break for lunch and time of the session's initiation may need a schedule group because it will require multiple time ranges to make up the schedule.

## Service

The service or service chosen here represent the TCP/IP suite port numbers that will most commonly be used to transport the named protocols or group of protocols. This will be a little different than Application Control which looks more closely at the packets to determine the actual protocol used to create them.

Without all six (possibly 8) of these things matching, the traffic will be declined. Each traffic flow requires a policy and the direction is important as well. Just because packets can go from point A to point B on port X does not mean that the traffic can flow from point B to point A on port X. A policy must be configured for each direction.

When designing a policy there is often reference to the traffic flow, but most communication is a two way connection so trying to determine the direction of the flow can be somewhat confusing. If traffic is HTTP web traffic the user sends a request to the web site, but most of the traffic flow will be coming from the web site to the user. Is the traffic flow considered to be from the user to the web site, the web site to the user or in both directions? For the purposes of determining the direction for a policy the important factor is the direction of the initiating communication. The user is sending a request to the web site so this is the initial communication and the web site is just responding to it so the traffic will be from the users network to the Internet.

A case where either side can initiate the communication like between two internal interfaces on the FortiGate unit would be a more likely situation to require a policy for each direction.

### What is not expressly allowed is denied

One of the fundamental ideas that can be found in just about any firewall is the rule than anything that is not expressly allowed is by default denied. This is the foundation for any strategy of protecting your network. Right out of the box, once you have your FortiGate device connected into your network and hooked up with your ISP your network is protected. Nothing is getting out or in so it is not very convenient, but you don't have to worry that between the time you hooked it up and the point that you got all of the policies in place that someone could have gotten in and done something to your resources. The reason that this needs to be kept in mind when designing policies is because you cannot assume that any traffic will be allowed just because it makes sense to do so. If you want any kind of traffic to make it past the FortiGate firewall you need to create a policy that will allow that traffic. To maintain the protection of the network should also make sure that the any policy you create allows only the traffic you intend to go only to where you specifically want it to go and when you want it to go there.

### Example

You have a web server on your network that is meant to provide a collaborative work environment web site for your employees and a partner company for a project over the course of the next 3 months.

It is theoretically possible to allow connections into your network to any device on that network for any service and at any time. The problem with this is that we might not want just anybody looking at those resources. Sadly, no matter how much it is wished otherwise, not everybody on the Internet can be trusted. Which means we now have to be very specific in our instructions as to what traffic to allow into the network. Each step that we take towards being more specific as to what we allow means that there is that much more that is not allowed and the level of protection of a resources is directly proportional to the amount of traffic that is not allowed. If somebody can't get at it they can't damage or steal it.

Limiting where the traffic is allowed to go to means that other computers on your network besides the web-server are protected.

- Limiting where the traffic is allowed to come from means that, if feasible, you can limit the systems that can access the web server to just employees or the partner company computers.
- Limiting the services to just web traffic means that a malicious person, even if they were connection from a computer at the partner organization could only use the features of web traffic to do anything malicious.
- Limiting the policy to the time span of the project would mean that even if the IT department forgot to remove the policy after the end of the project than no computer from the other company could be used to do anything malicious through the policy that allowed the traffic.

This is just a very basic example but it shows the underlying principles of how the idea that anything not expressly allowed is by default denied can be used to effectively protect your network.

## Policy order

Another important factor in how firewall policies work is the concept of precedence of order or if you prefer a more recognizable term, “first come, first served”.

It is highly likely that even after only a relatively small number of policies have been created that there will be some that overlap or are subsets of the parameters that the policies use to determine which policy should be matched against the incoming traffic. When this happens there has to be a method to determine which policy should be applied to the packet. The method which is used by most firewalls is based on the order of the sequence of the policies.

If all of the policies were placed in a sequential list the process to match up the packet would start at the top of the list and work its way down. It would compare information about the packet, specifically these points of information:

1. The interface the packet connected to the FortiGate firewall
2. The source of the packet. This can include variations of the address, user credentials or device
3. The destination of the packet. This can include address or Internet service
4. The interface the packet would need to use to get to the destination address based on the routing table
5. The service or port the packet is destined for
6. The time that the packet connected to the FortiGate

As soon as the a policy is reached that matches all of the applicable parameters, the instructions of that policy are applied and the search for any other matching policies is stopped. All subsequent policies are disregarded. Only 1 policy is applied to the packet.

If there is no matching policy among the policies that have been configured for traffic the packet finally drops down to what is always the last policy. It is an implicit policy. One of a few that are referred to by the term “policy0”. This policy denies everything.

The implicit policy is made up of the following settings:

- Incoming Interface: any
- Source Address: any
- Outgoing Interface: any
- Destination Address: any
- Action: DENY

The only setting that is editable in the implicit policy is the logging of violation traffic.

A logical best practice that comes from the knowledge of how this process works is to make sure that the more specific or specialized a policy is, the closer to the beginning of the sequence it should be. The more general a policy is the higher the likelihood that it could include in its range of parameters a more specifically targeted policy. The more specific a policy is, the higher the probability that there is a requirement for treating that traffic in a specific way.

## Example

For security reasons there is no FTP traffic allowed out of a specific subnet so there is a policy that states that any traffic coming from that subnet is denied if the service is FTP, so the following policy was created:

**Policy #1**

<b>Source Interface</b>	Internal1
<b>Source Address</b>	192.168.1.0/24
<b>Source User(s)</b>	<left at default setting>
<b>Source Device Type</b>	<left at default setting>
<b>Outgoing Interface</b>	WAN1
<b>Destination Address</b>	0.0.0.0/0.0.0.0
<b>Service</b>	FTP
<b>Schedule</b>	always
<b>Action</b>	deny

Now as these things usually go it turns out that there has to be an exception to the rule. There is one very secure computer on the subnet that is allowed to use FTP and once the content has been checked it can then be distributed to the other computer on the subnet. So a second firewall policy is created.

**Policy #2**

<b>Source Interface</b>	Internal1
<b>Source Address</b>	192.168.1.38/32
<b>Source User(s)</b>	<left at default setting>
<b>Source Device Type</b>	<left at default setting>
<b>Outgoing Interface</b>	WAN1
<b>Destination Address</b>	0.0.0.0/0.0.0.0
<b>Service</b>	FTP
<b>Schedule</b>	always
<b>Action</b>	Allow

By default, a policy that has just been created will be placed last in the sequence so that it is less likely to interfere with existing policies before it can be moved to its intended position. If you look at Policy #2 you will notice that it is essentially the same as Policy #1 exempt for the Source Address and the Action. You will also notice that the Source Address of the Policy #2 is a subset of the Source address in policy #1. This means that if nothing further is done, Policy #2 will never see any traffic because the traffic will always be matched by Policy #1 and processed before it has a chance to reach the second policy in the sequence. For both policies to work as intended Policy #2 needs to be moved to before Policy #1 in the sequence.

## Policy Identification

There are two ways to identify a policy. The most obvious is the policy name and this is easily read by humans, but with a little effort it is possible to have a policy without a name, therefore every policy has an ID number.

When looking at the policy listing it can appear as if the policies are identified by the sequence number in the far left column. The problem is that this number changes as the position of the policy in the sequence changes. The column that correctly identifies the policy, and the value sticks with the policy is the "ID" column. This column is not shown by default in the listing but can be added to the displayed columns by right clicking on the column heading bar and selecting it from the list of possible columns.

When looking in the configuration file the sequence is based upon the order of the policies as they are in the file just as they are in the list in the GUI. However, if you need to edit the policy in the CLI you must use the ID number.

## UUID Support

Universally Unique Identifier (UUID) attributes have been added to policies to improve functionality when working with FortiManager or FortiAnalyzer units. If required, the UUID can be set manually through the CLI.

CLI Syntax:

```
config firewall {policy/policy6/policy46/policy64}
  edit 1
    set uuid <example uuid: 8289ef80-f879-51e2-20dd-fa62c5c51f44>
  next
end
```

## Nturbo support CAPWAP traffic

NTurbo is used for IPSEC+IPS case. The IPSEC SA info is passed to NTURBO as part of VTAG for control packet and will be used for the xmit.

If the packets need to go through IPSEC interface, the traffic will be always offloaded to Nturbo. But for the case that SA has not been installed to NP6 because of hardware limitation or SA offload disable, the packets will be sent out through raw socket by IPS instead of Nturbo, since the software encryption is needed in this case.

## CLI :

Previously, NTurbo could only be enabled or disabled globally. The setting of np-acceleration has been added to the firewall policy context instead of just the global context.

CLI command in the firewall policy to enable/disable NTurbo acceleration.

```
config firewall policy
  edit 1
    set np-acceleration [enable|disable]
```

```
end
```

When IPS is enabled for VPN IPsec traffic, the data can be accelerated by NTurbo.

## Learning mode for policies

The learning mode feature is a quick and easy method for setting a policy to allow everything but to log it all so that it can later be used to determine what restrictions and protections should be applied. The objective is to monitor the traffic not act upon it while in Learning mode.

Once the **Learn** action is enabled, functions produce hard coded profiles that will be enabled on the policy. The following profiles are set up:

- AntiVirus (av-profile)
- Web Filter ( webfilter-profile)
- Anti Spam( spamfilter-profile )
- Data Leak Prevention (dlp-sensor )
- Intrusion Protection (ips-sensor )
- Application Control (application-list )
- Proxy Options (profile-protocol-options)

- 
- These UTM profiles are all using Flow mode
  - SSL inspection is always disable for the Learn option
  - These profiles are static and cannot be edited.
- 

Profiles that are not being used are:

- DNS Filter (Does not have a Flow mode)
- Web Application Firewall(Does not have a Flow mode)
- CASI(Almost all signatures in CASI require SSL deep inspection. Without SSL inspection, turning on CASI serves little purpose)

The ability to allow policies to be set to a learning mode is enabled on a per VDOM basis.

```
config system settings
    set gui-policy-learning [enable | disable]
end
```

Once the feature is enabled on the VDOM, Learn is an available **Action** option when editing a policy.

---

Because this feature requires a minimum level of logging capabilities, it is only available on FortiGates with hard drives. Smaller models may not be able to use this feature.

---

Once the Learning policy has been running for a sufficient time to collect needed information a report can be looked at by going to **Log & Report > Learning Report**.

The Report can be either a **Full Report** or a **Report Summary**

The time frame of the report can be **5 minutes**, **1 hour**, or **24 hours**.

The Learning Report includes:

### Deployment Methodology

- Test Details
  - Start time
  - End time
  - Model
  - Firmware
- Policy List

### Executive Summary

- Total Attacks Detected
- Top Application Category
- Top Web Category
- Top Web Domain
- Top Host by Bandwidth
- Host with Highest Session Count

### Security and Threat Prevention

- High Risk Applications
- Application Vulnerability Exploits
- Malware, botnets and Spyware/Adware
- At-Risk Devices and Hosts

### User Productivity

- Application Usage
  - Top Application Categories
  - Top Social Media Applications
  - Top Video/Audio Streaming Applications
  - Top Peer to Peer Applications
  - Top Gaming Applications
- Web Usage
  - Top Web Categories
  - Top Web Applications
  - Top Web Domains

## Policy Modes

You can operate your FortiGate or individual VDOMs in **Next Generation Firewall (NGFW) Policy Mode**.

You can enable NGFW policy mode by going to **System > Settings**, setting the **Inspection mode** to **Flow-based** and setting the NGFW mode to **Policy-based**. When selecting **NGFW policy-based** mode you also select the SSL/SSH Inspection mode that is applied to all policies

**Flow-based** inspection with profile-based **NGFW mode** is the default in FortiOS 5.6.

Inspection Mode	<b>Flow-based</b> Proxy
NGFW Mode	Profile-based <b>Policy-based</b>
SSL/SSH Inspection	<b>SSL</b> deep-inspection ▼

Or use the following CLI command:

```
config system settings
  set inspection-mode flow
  set policy-mode {standard | ngfw}
end
```

### NGFW policy mode and NAT

If your FortiGate is operating in NAT mode, rather than enabling source NAT in individual NGFW policies you go to **Policy & Objects > Central SNAT** and add source NAT policies that apply to all matching traffic. In many cases you may only need one SNAT policy for each interface pair. For example, if you allow users on the internal network (connected to port1) to browse the Internet (connected to port2) you can add a port1 to port2 Central SNAT policy similar to the following:

#### New Central SNAT Policy

Incoming Interface	 port1	×
	+	
Outgoing Interface	 port2	×
	+	
Source address	 all	×
	+	
Destination address	 all	×
	+	

☒ NAT

IP Pool Configuration	<b>Use Outgoing Interface Address</b> Use Dynamic IP Pool
Protocol	<b>ANY</b> TCP UDP SCTP Specify 0

### Application control in NGFW policy mode

You configure **Application Control** simply by adding individual applications to security policies. You can set the action to accept or deny to allow or block the applications.

Name 	Block YouTube		
Incoming Interface	 port1	▼	
Outgoing Interface	 port2	▼	
Source	 all	✕	
	+		
Destination	 all	✕	
	+		
Schedule	 always	▼	
Service	 ALL	✕	
	+		
Application	<div>  YouTube ✕         </div> <div>  YouTube_Channel.Access ✕         </div> <div>  YouTube_HD.Streaming ✕         </div> <div>  YouTube_Video.Access ✕         </div> <div>  YouTube_Video.Embedded ✕         </div> <div>+</div>		
URL Category	+		
Action	 ACCEPT  DENY  LEARN		

### Web Filtering in NGFW mode

You configure **Web Filtering** by adding URL categories to security policies. You can set the action to accept or deny to allow or block the applications.

Name 	Block Streaming Websites	
Incoming Interface	 port1	▼
Outgoing Interface	 port2	▼
Source	 all	✕
	+	
Destination	 all	✕
	+	
Schedule	 always	▼
Service	 ALL	✕
	+	
Application	+	
URL Category	Streaming Media and Download	✕
	+	
Action	 ACCEPT  <b>DENY</b>  LEARN	

### Other NGFW policy mode options

You can also combine both application control and web filtering in the same NGFW policy mode policy. Also if the policy accepts applications or URL categories you can also apply Antivirus, DNS Filtering, and IPS profiles in NGFW mode policies as well a logging and policy learning mode.

### Security profiles

Where security policies provide the instructions to the FortiGate unit for controlling what traffic is allowed through the device, the Security profiles provide the screening that filters the content coming and going on the network. Security profiles enable you to instruct the FortiGate unit about what to look for in the traffic that you don't want, or want to monitor, as it passes through the device.

A security profile is a group of options and filters that you can apply to one or more firewall policies. Security profiles can be used by more than one security policy. You can configure sets of security profiles for the traffic types handled by a set of security policies that require identical protection levels and types, rather than repeatedly configuring those same security profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict antivirus protection, traffic between trusted internal addresses might need moderate antivirus protection. To provide the different levels of protection, you might configure two separate profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Security profiles are available for various unwanted traffic and network threats. Each are configured separately and can be used in different groupings as needed. You configure security profiles in the Security Profiles menu and applied when creating a security policy by selecting the security profile type.

There is a separate handbook for the topic of the Security Profiles, but because the Security Profiles are applied through the Firewall policies it makes sense to have at least a basic idea of what the security profile do and how they integrate into the FortiGate's firewall policies. The following is a listing and a brief description of what the security profiles offer by way of functionality and how they can be configured into the firewall policies.

- HTTP
- SMTP
- POP3
- IMAP
- FTP
- NNTP
- MAPI
- DNS
- IM

## AntiVirus

Antivirus is used as a catch all term to describe the technology for protection against the transmission of malicious computer code sometimes referred to as malware. As anyone who has listened to the media has heard that the Internet can be a dangerous place filled with malware of various flavors. Currently, the malware that is most common in the Internet, in descending order, is Trojan horses, viruses, worms, adware, back door exploits, spyware and other variations. In recent years, not only has the volume of malicious software become greater than would have been believed when it first appeared but the level of sophistication has risen as well.

The Antivirus Filter works by inspecting the traffic that is about to be transmitted through the FortiGate. To increase the efficiency of effort it only inspects the traffic being transmitted via the protocols that it has been configured to check. Before the data moves across the FortiGate firewall from one interface to another it is checked for attributes or signatures that have been known to be associated with malware. If malware is detected, it is removed.

## Web Filtering

Malicious code is not the only thing to be wary of on the Internet. There is also the actual content. While the content will not damage or steal information from your computer there is still a number of reasons that would require protection from it.

In a setting where there are children or other sensitive people using the access provided by a connected computer there is a need to make sure that images or information that is not appropriate is not inadvertently displayed to them. Even if there is supervision, in the time it takes to recognize something that is inappropriate and then properly react can expose those we wish to protect. It is more efficient to make sure that the content cannot reach the screen in the first place.

In an organizational setting, there is still the expectation that organization will do what it can to prevent inappropriate content from getting onto the computer screens and thus provoking an Human Resources incident. There is also the potential loss of productivity that can take place if people have unfiltered access to the Internet. Some organizations prefer to limit the amount of distractions available to tempt their workers away from their duties.

The Web filter works primarily by looking at the destination location request for a HTTP(S) request made by the sending computer. If the URL is on a list that you have configured to list unwanted sites, the connection will be disallowed. If the site is part of a category of sites that you have configured to deny connections to the session will also be denied. You can also configure the content filter to check for specific key strings of data on the actual web site and if any of those strings of data appear the connection will not be allowed.

### **The configuration for each of these protocols is handled separately.**

DNS filtering is similar to Web Filtering from the viewpoint of the user. The difference is under the hood. When using regular Web Filtering, the traffic can go through some processing steps before it gets to the point where the web filter determines whether or not the traffic should be accepted or denied. Because the filtering takes place at the DNS level, some sites can be denied before a lot of the additional processing takes place. This can save resource usage on the FortiGate and help performance.

## **Application Control**

Application Control is designed to allow you to determine what applications are operating on your network and to also filter the use of these applications as required. Application control is also for outgoing traffic to prevent the use of applications that are against an organization's policy from crossing the network gateway to other networks. An example of this would be the use of proxy servers to circumvent the restrictions put in place using the Web Filtering.

## **Intrusion Protection (IPS)**

Intrusion Prevention System is almost self explanatory. In the same way that there is malware out on the Internet that the network needs to be protected from there are also people out there that take a more targeted approach to malicious cyber activity. No operating system is perfect and new vulnerabilities are being discovered all of the time. An intrusion prevention system is designed to look for activity or behavior that is consistent with attacks against your network. When attack like behavior is detected it can either be dropped or just monitored depending on the approach that you would like to take.

As new vulnerabilities are discovered they can be added to the IPS database so that the protection is current.

## **Anti-Spam**

Spam or unsolicited bulk email is said to account for approximately 90% of the email traffic on the Internet. Sorting through it is both time consuming and frustrating. By putting an email filter on policies that handle email traffic, the amount of spam that users have to deal with can be greatly reduced.

## **Data Leak Prevention (DLP)**

Data Leak Prevention is used to prevent sensitive information from leaving your network. When people think of security in the cyber-world one of the most common images is that of a hacker penetrating your network and making off with your sensitive information, but the other way that you can lose sensitive data is if someone already on the inside of your network sends it out. This does not have to be an act of industrial espionage. It can just be a case of not knowing the policies of the organization or a lack of knowledge of security or laws concerning privacy.

For instance, a company may have a policy that they will not reveal anyone's Social Security number, but an employee emails a number of documents to another company that included a lengthy document that has a Social Security number buried deep within it. There is not malicious intent but if the information got out there could be repercussions.

If an organization has any information in a digital format that it cannot afford for financial or legal reasons, to leave its network, it makes sense to have Data Leak Prevention in place as an additional layer of protection.

## VoIP

Voice over IP is essentially the protocols for transmitting voice or other multimedia communications over Internet Protocol networks such as the Internet. The Security Profiles VoIP options apply the SIP Application Level Gateway (ALG) to support SIP through the FortiGate unit. The SIP ALG can also be used to protect networks from SIP-based attacks.

## ICAP

Internet Content Adaptation Protocol (ICAP) off loads HTTP traffic to another location for specialized processing. The purpose of this module when triggered is to send the incoming HTTP traffic over to a remote server to be processed thus taking some of the strain off of the resources of the FortiGate unit. The reasons for the specialized process could be anything from more sophisticated Antivirus to manipulation of the HTTP headers and URLs.

Just like other components of the FortiGate, there is the option for different Proxy Option profiles so that you can be very granular in your control of the workings of the FortiGate. In the case of the Proxy Option profiles the thing that you will want to focus on is the matching up of the correct profile to a firewall policy that is using the appropriate protocols. If you are creating a Proxy Option profile that is designed for policies that control SMTP traffic into your network you only want to configure the settings that apply to SMTP. You do not need or want to configure the HTTP components.

The Web Application Firewall performs a similar role as devices such as Fortinet's FortiWeb, though in a more limited fashion. Its function is to protect internal web servers from malicious activity specific to those types of servers. This includes things like SQL injection, Cross site Scripting and trojans. It uses signatures and other straight forward methods to protect the web servers, but it is a case of turning the feature on or off and the actions are limited to **Allow**, **Monitor** or **Block**. To get protection that is more sophisticated, granular and intelligent, as well as having many more features, it is necessary to get a device like the FortiWeb that can devote more resources to the process. However, if your needs are simple, choosing to use the WAF feature built into the FortiGate should provide valuable protection.

The comfort client feature mitigates this potential issue by feeding a trickle of data while waiting for the scan to complete so as to let the user know that processing is taking place and that there hasn't been a failure in the transmission. This slow transfer rate continues until the antivirus scan is complete. Once the file has been successfully scanned without any indication of viruses the transfer will proceed at full speed.

Without prior approval the email should not be forwarded.

Please be environmentally friendly and don't print out emails

## Security Profile Groups

It may seem counter intuitive to have a topic on Security Profile Groups in the Firewall Chapter/Handbook when there is already a chapter/handbook on Security Profiles, but there are reasons.

- Security Profile Groups are used exclusively in the configuration of a firewall policy, which is described in the Firewall Chapter/Handbook.
- The CLI commands for creating and using Security Profile Groups are in the firewall configuration context of the command line structure of settings.

The purpose of Security Profile Groups is just the same as other groups such as Address, Service, and VIP groups. They are used to save time and effort in the administration of the FortiGate when there are a lot of policies with a similar pattern of Security Profile use. In a fairly basic network setup with a handful of policies it doesn't seem like it would be worth the effort to set up groups of security profiles but if you have a large complex configuration with hundreds of policies where many of them use the same security profiles it can definitely save some effort and help prevent missing adding an important profile from a policy. As an added benefit, when it comes time to add or change the profiles for the policies that use the Security Profile Groups, the changes only have to be made to the group, not each policy.

The most difficult part about using Security Profile Groups is making them visible in the GUI.

### Making Security Profile Groups visible in the GUI

By default, the Security Profile Groups are not visible in the GUI. Neither the ability to assign one to a policy nor the ability to configure the members of a group are available by default. You will not find the option to enable Security Profile Groups under **System > Feature Visibility** either. Instead, they only become visible in the GUI once one has been created and assigned to a policy. This must be done the first time through the CLI using the following syntax:

```
config system settings
    set gui-dynamic-profile-display enable
end
```

#### Step 1 - Create a Security Profile Group:

Enter the command:

```
config firewall profile-group
```

Use the edit command to give a name to and create a new Security Profile Group

```
(profile-group) # edit test-group
```

Configure the members of the group by setting the name of the desired profile in the field for the related profile/sensor/list. The options are:

av-profile	Name of an existing Antivirus profile.
webfilter-profile	Name of an existing Web filter profile.
dnsfilter-profile	Name of an existing DNS filter profile.
spamfilter-profile	Name of an existing Spam filter profile.
dlp-sensor	Name of an existing DLP sensor.
ips-sensor	Name of an existing IPS sensor.
application-list	Name of an existing Application list.
voip-profile	Name of an existing VoIP profile.
icap-profile	Name of an existing ICAP profile.

waf-profile	Name of an existing Web application firewall profile.
profile-protocol-options	Name of an existing Protocol options profile.
ssl-ssh-profile	Name of an existing SSL SSH profile.

Example:

```
set av-profile default
set profile-protocol-options default
end
```

Always set the `profile-protocol-options` setting before attempting to save the profile group. If this is not set, you will get the error:

```
node_check_object fail! for profile-protocol-options
Attribute 'profile-protocol-options' MUST be set.
Command fail. Return code -56
```

## Step 2 - Add a Security Profile to a policy

Now that there is group to add to a policy we can configure a policy to allow the use of a Security Policy group. This is also done in the CLI.

In the following example only the command necessary to enable the use and pick of a Security Policy group have been listed.

```
config firewall policy
edit 0
set utm-status enable
set profile-type group
set profile-group test-group
```

## Step 3 - The appearance in the GUI of the Security Profile Group configuration features

- Under **Security Profiles** there is a menu item called **Profile Groups** that can be used to create new and edit existing profile groups.
- In the **Edit Policy** window for **IPv4** and **IPv6** policies there is a **Use Security Profile Group** field to enable or disable the use of the groups.
  - In the window, policy groups can be created or edited by clicking on the appropriate icons next to or in the drop down menu
- In the policy listing window there is a Security Profiles column.
  - Right or left clicking on the icon for the group brings up editing options either via a slide out window or a drop down menu, respectively.

## Proxy Option Components

Any time a security profile that requires the use of a proxy is enabled the Proxy Options field will be displayed. Certain inspections defined in security profiles require that the traffic be held in proxy while the inspection is carried out and so the Proxy Options are there to define the parameters of how the traffic will be processed and to what level the traffic will be processed. In the same way that there can be multiple security profiles of a single type there can also be a number of unique Proxy Option profiles so that as the requirements for a policy differ from one policy to the next you can also configure a different Proxy Option profile for each individual policy or you can use one profile repeatedly.

The Proxy Options refer to the handling of the following protocols:

- HTTP
- SMTP
- POP3
- IMAP
- FTP
- NNTP
- MAPI
- DNS
- IM

The configuration for each of these protocols is handled separately.

It should also be noted that these configurations apply to only the Security Profiles Proxy-based processes and not the Flow-based processes.

## The use of different proxy profiles and profile options

Just like other components of the FortiGate, there is the option for different Proxy Option profiles so that you can be very granular in your control of the workings of the FortiGate. In the case of the Proxy Option profiles the thing that you will want to focus on is the matching up of the correct profile to a firewall policy that is using the appropriate protocols. If you are creating a Proxy Option profile that is designed for policies that control SMTP traffic into your network you only want to configure the settings that apply to SMTP. You do not need or want to configure the HTTP components.

## Oversized File Log

This setting is for those that would like to log the occurrence of oversized files being processed. It does not change how they are processed it only enables the FortiGate unit to log that they were either blocked or allowed through. A common practice is to allow larger files through without antivirus processing. This allows you to get an idea of how often this happens and decide on whether or not to alter the settings relating to the treatment of oversized files.

The setting of the threshold for what is considered to be an oversized file is located in the Oversized File / Email Threshold that is found in some of the protocol options for the Proxy Options.

## Protocol Port Mapping

While each of the protocols listed has a default TCP port that is commonly used, the level of granularity of control on the FortiGate firewall allows that the port used by the protocols can be individually modified in each separate Profile. It can also be set to inspect any port with flowing traffic for that particular protocol. The headers of the

packets will indicate which protocol generated the packet. To optimize the resources of the unit the mapping and inspection of protocols can be enabled or disabled depending on your requirements.

### Comfort Clients

When proxy-based antivirus scanning is enabled, the FortiGate unit buffers files as they are downloaded. Once the entire file is captured, the FortiGate unit begins scanning the file. During the buffering and scanning procedure, the user must wait. After the scan is completed, if no infection is found, the file is sent to the next step in the process flow. If the file is a large one this part of the process can take some time. In some cases enough time that some users may get impatient and cancel the download.

The comfort client feature to mitigates this potential issue by feeding a trickle of data while waiting for the scan to complete so as to let the user know that processing is taking place and that there hasn't been a failure in the transmission. This slow transfer rate continues until the antivirus scan is complete. Once the file has been successfully scanned without any indication of viruses the transfer will proceed at full speed.

If there is evidence of an infection the FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead, the download stops and the user is left with a partially downloaded file. If the user tries to download the same file again within a short period of time, the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting is available for HTTP and FTP traffic. If your FortiGate unit supports SSL content scanning and inspection, you can also configure client comforting for HTTPS and FTPS traffic.

Buffering the entire file allows the FortiGate unit to eliminate the danger of missing an infection due to fragmentation because the file is reassembled before examination. Client comforting can send unscanned and therefore potentially infected content to the client. You should only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

### Oversized File/Email Threshold

This is another feature that is related to antivirus scanning. The FortiGate unit has a finite amount of resources that can be used to buffer and scan a file. If a large file such as an ISO image or video file was to be downloaded this could not only overwhelm the memory of the FortiGate, especially if there were other large files being downloaded at the same time, but could exceed it as well. For this reason, how to treat large files needs to be addressed.

A threshold is assigned to determine what should be considered an oversize file or email. This can be set at any size from 1 MB to 50 MB. Any file or email over this threshold will not be processed by the Antivirus Security Profiles. Once a file is determined to be oversized it must be then determined whether to allow it or to block it.

These settings are not a technical decision but a policy one that will depend on your comfort level with letting files into your network. As there often is, there is a compromise between convenience or ease of use and security. If you want to go for a high peace of mind level you can configure the firewall to block oversized files and thus no files would be coming into the network that have not been scanned. If you are looking for optimizing the memory of the FortiGate unit and making sure that everybody is getting the files they want, you can lower the threshold and allow files that are over the threshold.

It should be noted that in terms of probability that malware is more likely to be found in smaller files than in larger files. A number of administrators take this into account when they lower the default threshold so as to lessen the impact on memory if they see the FortiGate unit going into conserve mode on a regular basis.

### Chunked Bypass

The HTTP section allows the enabling of “Chunked Bypass”. This refers to the mechanism in version 1.1 of HTTP that allows a web server to start sending chunks of dynamically generated output in response to a request before actually knowing the actual size of the content. Where dynamically generated content is concerned this means that there is a faster initial response to HTTP requests. From a security stand point it means that the content will not be held in the proxy as an entire file before proceeding.

### Allow Fragmented Messages

The specifications of RFC 2046 allow for the breaking up of emails and sending the fragments in parallel to be rebuilt and read at the other end by the mail server. It was originally designed to increase the performance over slower connections where larger email messages were involved. It will depend on your mail configuration if this is even possible for your network but outside of Microsoft Outlook and Outlook Express, not many email clients are set up to break up messages like this. The drawback of allowing this feature is that if malware is broken up between multiple fragments of the message the risk is run that it will not be detected by some antivirus configurations because the code may not all be present at the same time to identify.

### Append Email Signature

The Append Email Signature is used when an organization would like to ensure that over and above our in this case underneath the existing personal signatures of the sender, all of the emails going out of their network have the appropriate “boilerplate”, for lack of a better term. These appended emails do not replace existing signatures. They are as the feature states, appended to the email.

Examples could include things like:

- Without prior approval the email should not be forwarded.
- Please be environmentally friendly and don't print out emails
- For questions regarding the purchasing of our products please call...

It can be anything that the organization would like as long as it is in text format. The use of this feature usually works best in an environment where there is some standardization of what goes into the personal signatures of the senders so that there is no duplication or contradiction of information in the signatures.

### SSL/SSH Inspection

While the profile configuration for **SSL/SSH Inspection** is found in the **Security Profiles** section it is enabled in the firewall policy by enabling any of the security profiles. Choosing which of the **SSL/SSH Inspection** profiles is all that can really be done in the policy.

The reason for having this inspection as part of the policy is the wide spread use of encryption by both legitimate and malicious actors. The legitimate users of the Internet use encryption to hide their information from snooping bad guy but the bad guys use encryption to hide their malicious content from being scanned for viruses and other malicious code by security devices.

By using the correct SSL certificates, the FortiGate can open up encrypted traffic and inspect it for malicious content that would otherwise make it past the other profiles because they couldn't read the encrypted traffic.

There are two basic types of inspection:

- Certificate inspection, which only looks at the certificate that encrypted the packets to make sure that it is a recognized and valid certificate.
- Full inspection, or deep inspection, that looks at all of the content of the packet. While more thorough, it also takes up more resources to perform.

### HTTP Strict Transport Security (HSTS) Protocol

HSTS is a protocol used by Google and other web browsers to prevent man-in-the-middle attacks.

When performing deep inspection, the FortiGate intercepts the https traffic and would send its own self-signed CA certificate to the browser. If the browser is configured to use HSTS connections, it would refuse the FortiGate CA certificate since it is not on the trusted list for Google servers.

To keep the CA certificate from being refused, the HSTS settings should be cleared from the browser. Instructions for this vary between browsers.

To gain a deeper understanding read the **SSL/SSH Inspection** section in the **Security Profile** chapter.

### Mirroring SSL inspected traffic

It is possible to "mirror" or send a copy of traffic decrypted by SSL inspection to one or more FortiGate interfaces so that the traffic can be collected by a raw packet capture tool for archiving or analysis. This feature is available if the inspection mode is set to flow-based.

Decryption, storage, inspection, and use decrypted content is subject to local privacy rules. Use of these features could enable malicious users with administrative access to your FortiGate to harvest sensitive information submitted using an encrypted channel.

In this example, the setting enables the policy to send all traffic decrypted by the policy to the FortiGate port1 and port2 interfaces.

```
config firewall policy
  edit 0
    set ssl-mirror enable
    set ssl-mirror-intf port1 port2
  end
```

### RPC over HTTP

How protocol options profiles and SSL inspection profiles handle RPC (Remote Procedure Calls) over HTTP traffic can be configured separately from normal HTTP traffic. The configuration is done in the CLI.

### Configuration in Protocol Options

```
config firewall profile-protocol-options
  edit 0
    set rpc-over-http [disable|enable]
  end
```

## Configuration in SSL/SSH inspection

```
config firewall ssl-ssh-profile
edit deep inspection
set rpc-over-http [disable|enable]
end
```

## IPv6

Internet Protocol version 6 (IPv6) will succeed IPv4 as the standard networking protocol of the Internet. IPv6 provides a number of advances over IPv4 but the primary reason for its replacing IPv4 is its limitation in addresses. IPv4 uses 32 bit addresses which means there is a theoretical limit of 2 to the power of 32. The IPv6 address scheme is based on a 128 bit address or a theoretical limit of 2 to the power of 128.

Possible Addresses:

- IPv4 = 4,294,967,296 (over 4 billion)
- IPv6 = 340,282,366,920,938,463,374,607,431,768,211,456 (over 340 undecillion - We had to look that term up. We didn't know what a number followed by 36 digits was either)

Assuming a world population of approximately 8 billion people, IPv6 would allow for each individual to have approximately 42,535,295,865,117,200,000,000,000,000 devices with an IP address. That's 42 quintillion devices.

There is little likelihood that you will ever need to worry about these numbers as any kind of serious limitation in addressing but they do give an idea of the scope of the difference in the available addressing.

Aside from the difference of possible addresses there is also the different formatting of the addresses that will need to be addressed.

A computer would view an IPv4 address as a 32 bit string of binary digits made up of 1s and 0s, broken up into 4 octets of 8 digits separated by a period “.”

Example:

```
10101100.00010000.11111110.00000001
```

To make number more user friendly for humans we translate this into decimal, again 4 octets separated by a period “.” which works out to:

```
172.16.254.1
```

A computer would view an IPv6 address as a 128 bit string of binary digits made up of 1s and 0s, broken up into 8 octets of 16 digits separated by a colon “:”

```
1000000000000001:0000110110111000:101011000001000:1111111000000001:0000000000000000
0:0000000000000000:0000000000000000:0000000000000000
```

To make number a little more user friendly for humans we translate this into hexadecimal, again 8 octets separated by a colon “:” which works out to:

```
8001:0DB8:AC10:FE01:0000:0000:0000:0000:
```

Because any four-digit group of zeros within an IPv6 address may be reduced to a single zero or altogether omitted, this address can be shortened further to:

```
8001:0DB8:AC10:FE01:0:0:0:0
```

or

8001:0DB8:AC10:FE01::

Some of the other benefits of IPv6 include:

- More efficient routing
- Reduced management requirement
- Stateless auto-reconfiguration of hosts
- Improved methods to change Internet Service Providers
- Better mobility support
- Multi-homing
- Security
- Scoped address: link-local, site-local and global address space

## IPv6 in FortiOS

From an administrative point of view IPv6 works almost the same as IPv4 in FortiOS. The primary differences are the use of IPv6 format for addresses and fewer address types for IPv6. There is also no need for NAT if the FortiGate firewall is the interface between IPv6 networks. If the subnets attached to the FortiGate firewall are IPv6 and IPv4 NAT can be configured between the 2 different formats. This will involve either configuring a dual stack routing or IPv4 tunneling configuration. The reason for this is simple. NAT was developed primarily for the purpose of extending the number of usable IPv4 addresses. IPv6's addressing allows for enough available addresses so the NAT is no longer necessary.

When configuring IPv6 in FortiOS, you can create a dual stack route or IPv4-IPv6 tunnel. A dual stack routing configuration implements dual IP layers, supporting both IPv4 and IPv6, in both hosts and routers. An IPv4-IPv6 tunnel is essentially similar, creating a tunnel that encapsulates IPv6 packets within IPv4 headers that carry these IPv6 packets over IPv4 tunnels. The FortiGate unit can also be easily integrated into an IPv6 network. Connecting the FortiGate unit to an IPv6 network is exactly the same as connecting it to an IPv4 network, the only difference is that you are using IPv6 addresses.

By default the IPv6 settings are not displayed in the Web-based Manager. It is just a matter of enabling the display of these feature to use them through the web interface. To enable them just go to **System > Feature Select** and select **IPv6**. Once enabled, you will be able to use IPv6 addresses as well as the IPv4 addressing for the following FortiGate firewall features:

- Static routing
- Policy Routing
- Packet and network sniffing
- Dynamic routing (RIPv6, BGP4+, and OSPFv3)
- IPsec VPN
- DNS
- DHCP
- SSL VPN
- Network interface addressing
- Security Profiles protection
- Routing access lists and prefix lists
- NAT/Route and Transparent mode
- NAT 64 and NAT 66
- IPv6 tunnel over IPv4 and IPv4 tunnel over IPv6

- Logging and reporting
- Security policies
- SNMP
- Authentication
- Virtual IPs and groups
- IPv6 over SCTP
- IPv6-specific troubleshooting, such as ping6

## Dual Stack routing configuration

Dual stack routing implements dual IP layers in hosts and routers, supporting both IPv6 and IPv4. A dual stack architecture supports both IPv4 and IPv6 traffic and routes the appropriate traffic as required to any device on the network. Administrators can update network components and applications to IPv6 on their own schedule, and even maintain some IPv4 support indefinitely if that is necessary. Devices that are on this type of network, and connect to the Internet, can query Internet DNS servers for both IPv4 and IPv6 addresses. If the Internet site supports IPv6, the device can easily connect using the IPv6 address. If the Internet site does not support IPv6, then the device can connect using the IPv4 addresses. In the FortiOS dual stack architecture it is not just the basic addressing functions that operate in both versions of IP. The other features of the appliance such as Security Profiles and routing can also use both IP stacks.

If an organization with a mixed network uses an Internet service provider that does not support IPv6, they can use an IPv6 tunnel broker to connect to IPv6 addresses that are on the Internet. FortiOS supports IPv6 tunneling over IPv4 networks to tunnel brokers. The tunnel broker extracts the IPv6 packets from the tunnel and routes them to their destinations.

## IPv6 Tunneling

IPv6 Tunneling is the act of tunneling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. This is different than Network Address Translation (NAT) because once the packet reaches its final destination the true originating address of the sender will still be readable. The IPv6 packets are encapsulated within packets with IPv4 headers, which carry their IPv6 payload through the IPv4 network. This type of configuration is more appropriate for those who have completely transitional over to IPv6, but need an Internet connection, which is still mostly IPv4 addresses.

The key to IPv6 tunneling is the ability of the 2 devices, whether they are a host or a network device, to be dual stack compatible. They have to be able to work with both IPv4 and IPv6 at the same time. In the process the entry node of the tunnel portion of the path will create an encapsulating IPv4 header and transmit the encapsulated packet. The exit node at the end of the tunnel receives the encapsulated packet. The IPv4 header is removed. The IPv6 header is updated and the IPv6 packet is processed.

There are two types of tunnels in IPv6:

<b>Automatic tunnels</b>	Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address – the IPv6 address of the destination host includes information about which IPv4 address the packet should be tunneled to.
<b>Configured tunnels</b>	Configured tunnels must be configured manually. These tunnels are used when using IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the endpoints of the tunnel must be specified.

## Tunnel Configurations

There are a few ways in which the tunneling can be performed depending on which segment of the path between the end points of the session the encapsulation takes place.

<b>Network Device to Network Device</b>	Dual stack capable devices connected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans one segment of the path taken by the IPv6 packets.
<b>Host to Network Device</b>	Dual stack capable hosts can tunnel IPv6 packets to an intermediary IPv6 or IPv4 network device that is reachable through an IPv4 infrastructure. This type of tunnel spans the first segment of the path taken by the IPv6 packets.
<b>Host to Host</b>	Dual stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans the entire path taken by the IPv6 packets.
<b>Network Device to Host</b>	Dual stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. This tunnel spans only the last segment of the path taken by the IPv6 packets.

Regardless of whether the tunnel starts at a host or a network device, the node that does the encapsulation needs to maintain soft state information, such as the maximum transmission unit (MTU), about each tunnel in order to process the IPv6 packets.

## Tunneling IPv6 through IPsec VPN

A variation on the tunneling IPv6 through IPv4 is using an IPsec VPN tunnel between two FortiGate devices. FortiOS supports IPv6 over IPsec. In this sort of scenario, 2 networks using IPv6 behind FortiGate units are separated by the Internet, which uses IPv4. An IPsec VPN tunnel is created between the 2 FortiGate units and a tunnel is created over the IPv4 based Internet but the traffic in the tunnel is IPv6. This has the additional advantage of making the traffic secure as well.

## NAT

NAT or Network Address Translation is the process that enables a single device such as a router or firewall to act as an agent between the Internet or Public Network and a local or private network. This “agent”, in real time, translates the source IP address of a device on one network interface, usually the Internal, to a different IP address as it leaves another interface, usually the interface connected to the ISP and the Internet. This enables a single public address to represent a significantly larger number of private addresses.

## The Origins of NAT

In order to understand NAT it helps to know why it was created. At one time, every computer that was part of a network had to have its own addresses so that the other computers could talk to it. There were a few protocols in use at the time, some of which were only for use on a single network, but of those that were routable, the one that had become the standard for the Internet was IP (Internet Protocol) version 4.

When IP version 4 addressing was created nobody had any idea how many addresses would be needed. The total address range was based on the concept of 2 to the 32nd power, which works out to be 4 294 967 296 potential addresses. Once you eliminate some of those for reserved addresses, broadcast addresses, network addresses,

multicasting, etc., you end up with a workable scope of about 3.2 million addressees. This was thought to be more than enough at the time. The designers were not expecting the explosion of personal computing, the World Wide Web or smart phones. As of the beginning of 2012, some estimate the number of computers in the world in the neighborhood of 1 billion, and most of those computer users are going to want to be on the Internet or Search the World Wide Web. In short, we ran out of addresses.

This problem of an address shortage was realized before we actually ran out, and in the mid 1990s 2 technical papers called RFCs numbered 1631 (<http://www.ietf.org/rfc/rfc1631.txt>) and 1918 (<http://tools.ietf.org/html/rfc1918>), proposed components of a method that would be used as a solution until a new addressing methodology could be implemented across the Internet infrastructure. For more information on this you can look up IP version 6.

RFC 1631 described a process that would allow networking devices to translate a single public address to multiple private IP addresses and RFC 1918 laid out the use of the private addresses. The addresses that were on the Internet (Public IP addresses) could not be duplicated for them to work as unique addresses, but behind a firewall, which most large institutions had, they could use their own Private IP addresses for internal use and the internal computers could share the external or Public IP address.

To give an idea on a small scale how this works, image that a company has a need for 200 computer addresses. Before Private IP addresses and NAT the company would have purchased a full Class C address range which would have been 254 usable IP addresses; wasting about 50 addresses. Now with NAT, that company only needs 1 IP address for its 200 computers and this leaves the rest of the IP addresses in that range available for other companies to do the same thing.

NAT gives better value than it would first appear because it is not 253 companies that can use 254 addresses but each of those 254 companies could set up their networking infrastructures to use up to thousands of Private IP addresses, more if they don't all have to talk to the Internet at the same time. This process enabled the Internet to keep growing even though we technically have many more computers networked than we have addresses.

## Dynamic NAT

Dynamic NAT maps the private IP addresses to the first available Public Address from a pool of possible Addresses. In the FortiGate firewall this can be done by using IP Pools.

## Overloading

This is a form of Dynamic NAT that maps multiple private IP address to a single Public IP address but differentiates them by using a different port assignment. This is probably the most widely used version of NAT. This is also referred to as PAT (Port Address Translation) or Masquerading.

An example would be if you had a single IP address assigned to you by your ISP but had 50 or 60 computers on your local network.

Say the internal address of the interface connected to the ISP was 256.16.32.65 (again an impossible address) with 256.16.32.64 being the remote gateway. If you are using this form of NAT any time one of your computers accesses the Internet it will be seen from the Internet as 256.16.32.65. If you wish to test this go to 2 different computers and verify that they each have a different private IP address then go to a site that tells you your IP address such as [www.ipchicken.com](http://www.ipchicken.com). You will see that the site gives the same result of 256.16.32.65, if it existed, as the public address for both computers.

As mentioned before this is sometimes called Port Address Translation because network device uses TCP ports to determine which internal IP address is associated with each session through the network device. For example, if you have a network with internal addresses ranging from 192.168.1.1 to 192.168.1.255 and you have 5 computers all trying to connect to a web site which is normally listening on port 80 all of them will appear to the

remote web site to have the IP address of 256.16.32.65 but they will each have a different sending TCP port, with the port numbers being somewhere between 1 and 65 535, although the port numbers between 1 to 1024 are usually reserved or already in use. So it could be something like the following:

192.168.1.10	256.16.32.65:	port 486
192.168.1.23	256.16.32.65:	port 2409
192.168.1.56	256.16.32.65:	port 53763
192.168.1.109	256.16.32.65:	port 5548
192.168.1.201	256.16.32.65:	port 4396

And the remote web server would send the responding traffic back based on those port numbers so the network device would be able to sort through the incoming traffic and pass it on to the correct computer.

## Overlapping

Because everybody is using the relative same small selection of Private IP addresses it is inevitable that there will be two networks that share the same network range that will need to talk with each other. This happens most often over Virtual Private Networks or when one organization ends up merging with another. This is a case where a private IP address may be translated into a different private IP address so there are no issues with conflict of addresses or confusion in terms of routing.

An example of this would be when you have a Main office that is using an IP range of 172.16.0.1 to 172.20.255.255 connecting through a VPN to a recently acquired branch office that is already running with an IP range of 172.17.1.1 to 172.17.255.255. Both of these ranges are perfectly valid but because the Branch office range is included in the Main Office range any time the system from the Main office try to connect to an address in the Branch Office the routing the system will not send the packet to the default gateway because according to the routing table the address is in its own subnet.

The plan here would be to NAT in both directions so that traffic from neither side of the firewall would be in conflict and they would be able to route the traffic. Everything coming from the Branch Office could be assigned an address in the 192.168.1.1 to 192.168.1.255 range and everything from the Main office going to the Branch Office could be assigned to an address in the 192.168.10.1 to 192.168.10.255 range.

## Static NAT

In Static NAT one internal IP address is always mapped to the same public IP address.

In FortiGate firewall configurations this is most commonly done with the use of Virtual IP addressing.

An example would be if you had a small range of IP addresses assigned to you by your ISP and you wished to use one of those IP address exclusively for a particular server such as an email server.

Say the internal address of the Email server was 192.168.12.25 and the Public IP address from your assigned addresses range from 256.16.32.65 to 256.16.32.127. Many readers will notice that because one of the numbers is above 255 that this is not a real Public IP address. The Address that you have assigned to the interface connected to your ISP is 256.16.32.66, with 256.16.32.65 being the remote gateway. You wish to use the address of 256.16.32.70 exclusively for your email server.

When using a Virtual IP address you set the external IP address of 256.16.32.70 to map to 192.168.12.25. This means that any traffic being sent to the public address of 256.16.32.70 will be directed to the internal computer at the address of 192.168.12.25

When using a Virtual IP address, this will have the added function that when ever traffic goes from 192.168.12.25 to the Internet it will appear to the recipient of that traffic at the other end as coming from 256.16.32.70.

You should note that if you use Virtual IP addressing with the Port Forwarding enabled you do not get this reciprocal effect and must use IP pools to make sure that the outbound traffic uses the specified IP address.

## Benefits of NAT

### More IP addresses Available while Conserving Public IP Addresses

As explained earlier, this was the original intent of the technology and does not need to be gone into further.

### Financial Savings

Because an organization does not have to purchase IP addresses for every computer in use there is a significant cost savings due to using the process of Network Address Translation.

### Security Enhancements

One of the side benefits of the process of NAT is an improvement in security. Individual computers are harder to target from the outside and if port forwarding is being used computers on the inside of a firewall are less likely to have unmonitored open ports accessible from the Internet.

### Ease of Compartmentalization of Your Network

With a large available pool of IP addresses to use internally a network administrator can arrange things to be compartmentalized in a rational and easily remembered fashion and networks can be broken apart easily to isolate for reasons of network performance and security.

## Example

You have a large organization that for security reasons has certain departments that do not share network resources.

You can have the main section of the organization set up as follows;

<b>Network Devices</b>	192.168.1.1 to 192.168.1.25
<b>Internal Servers</b>	192.168.1.26 to 192.168.1.50
<b>Printers</b>	192.168.1.51 to 192.168.1.75
<b>Administration Personnel</b>	192.168.1.76 to 192.168.1.100
<b>Sales People</b>	192.168.1.101 to 192.168.1.200
<b>Marketing</b>	192.168.1.201 to 192.168.1.250

You could then have the following groups broken off into separate subnets:

<b>Accounting</b>	192.168.100.1 to 192.168.100.255
-------------------	----------------------------------

<b>Research and Development</b>	172.16.1.1 to 172.16.255.255
<b>Executive Management</b>	192.168.50.1 to 192.168.50.255
<b>Web sites and Email Servers</b>	10.0.50.1 to 10.0.50.255

These addresses do not have to be assigned right away but can be used as planned ranges.

## NAT in Transparent Mode

Similar to operating in NAT mode, when operating a FortiGate unit in Transparent mode you can add security policies and:

- Enable NAT to translate the source addresses of packets as they pass through the FortiGate unit.
- Add virtual IPs to translate destination addresses of packets as they pass through the FortiGate unit.
- Add IP pools as required for source address translation

A FortiGate unit operating in Transparent mode normally has only one IP address - the management IP. To support NAT in Transparent mode, you can add a second management IP. These two management IPs must be on different subnets. When you add two management IP addresses, all FortiGate unit network interfaces will respond to connections to both of these IP addresses.

Use the following steps to configure NAT in Transparent mode:

1. Add two management IPs
2. Add an IP pool to the WAN1 interface
3. Add an Internal to WAN1 security policy

You can add the security policy from the web-based manager and then use the CLI to enable NAT and add the IP pool.

The usual practice of NATing in transparent mode makes use of two management IP addresses that are on different subnets, but this is not an essential requirement in every case.

If there is a router between the client systems and the FortiGate unit you can use the router's capabilities of tracking sessions to assign NATed addresses from an IP pool to the clients even if the assigned address don't belong to a subnet on your network.

## Example

Client computer has an IP address of 1.1.1.33 on the subnet 1.1.1.0/24.

Router "A" sits between the client computer and the FortiGate (in Transparent mode) with the IP address of 1.1.1.1 on the client's side of the router and the IP address of 192.168.1.211 on the FortiGate's side of the router.

Use NAT to assign addresses from an address pool of 9.9.9.1 to 9.9.9.99 to traffic coming from gateway of 192.168.1.211.

To enable the return traffic to get to the original computer, set up a static route that assigns any traffic with a destination of 9.9.9.0/24 to go through the 192.168.1.211 gateway. As long as the session for the outgoing traffic

has been maintained, communication between the client computer and the external system on the other side of the FortiGate will work.

.

## Central NAT Table

The central NAT table enables you to define, and control with more granularity, the address translation performed by the FortiGate unit. With the NAT table, you can define the rules which dictate the source address or address group and which IP pool the destination address uses.

While similar in functionality to IP pools, where a single address is translated to an alternate address from a range of IP addresses, with IP pools there is no control over the translated port. When using the IP pool for source NAT, you can define a fixed port to guarantee the source port number is unchanged. If no fix port is defined, the port translation is randomly chosen by the FortiGate unit. With the central NAT table, you have full control over both the IP address and port translation.

The FortiGate unit reads the NAT rules in a top-down methodology, until it hits a matching rule for the incoming address. This enables you to create multiple NAT policies that dictate which IP pool is used based on the source address. The NAT policies can be rearranged within the policy list as well. NAT policies are applied to network traffic after a security policy.

## NAT 64 and NAT46

NAT64 and NAT46 are the terms used to refer to the mechanism that allows IPv6 addressed hosts to communicate with IPv4 addressed hosts and vice-versa. Without such a mechanism an IPv6 node on a network such as a corporate LAN would not be able to communicate with a web site that was still in a IPv4 only environment and IPv4 environments would not be able to connect to IPv6 networks.

One of these setups involves having at least 2 interfaces, 1 on an IPv4 network and 1 on an IPv6 network. The NAT64 server synthesizes AAAA records, used by IPv6 from A records used by IPv4. This way client-server and peer to peer communications will be able to work between an IPv6 only client and an IPv4 server without making changes to either of the end nodes in the communication transaction. The IPv6 network attached to the FortiGate unit should be a 32 bit segment, (for instance 64:ff9b::/96, see RFC 6052 and RFC 6146). IPv4 address will be embedded into the communications from the IPv6 client.

Because the IPv6 range of addresses is so much larger than the IPv4 range, a one to one mapping is not feasible. Therefore the NAT64 function is required to maintain any IPv6 to IPv4 mappings that it synthesizes. This can be done either statically by the administrator or automatically by the service as the packets from the IPv6 network go through the device. The first method would be a stateless translation and the second would be a stateful translation. NAT64 is designed for communication initiated from IPv6 hosts to IPv4 addresses. It is address mapping like this that allows the reverse to occur between established connections. The stateless or manual method is an appropriate solution when the NAT64 translation is taking place in front of legacy IPv4 servers to allow those specific servers to be accessed by remote IPv6-only clients. The stateful or automatic solution is best used closer to the client side when you have to allow some specific IPv6 clients to talk to any of the IPv4-only servers on the Internet.

There are currently issues with NAT64 not being able to make everything accessible. Examples would be SIP, Skype, MSN, Goggle talk, and sites with IPv4 literals. IPv4 literals being IPv4 addresses that are imbedded into content rather than a FQDN.

Policies that employ NAT64 or NAT46 can be configured from the web-based manager as long as the feature is enabled using the Features setting found at **System > Config > Features**.

- To create a NAT64 policy go to **Policy & Objects > NAT64 Policy** and select **Create New**.
- To create a NAT46 policy go to **Policy > NAT46 Policy** and select **Create New**.

The difference between these NAT policies and regular policies is that there is no option to use the security profiles and sensors.

NAT64 CLAT traffic is now supported by the FortiGate. CLAT traffic comes from devices that use the SIIT translator that plays a part in affecting IPv6 - IPv4 NAT translation.

## NAT64 CLAT

NAT64 CLAT traffic is supported by FortiOS. CLAT traffic comes from devices that use the SIIT translator that plays a part in affecting IPv6 - IPv4 NAT translation.

## NAT 66

NAT 66 is Network Address Translation between 2 IPv6 network. The basic idea behind NAT 66 is no different than the regular NAT between IPv4 networks that we are all used to. The difference are in the mechanics of how it is performed, mainly because of the complexity and size of the addresses that are being dealt with.

In an IPv4 world, the reason for the use of NAT was usually one or a combination of the following 3 reasons:

- Improved security - actual addresses behind NAT are virtually hidden
- Amplification of addresses - hundreds of computers can use as little as a single public IP address
- Internal address stability - there is control of internal addressing. The addresses can stay the same even if Internet Service Providers change.

In these days of security awareness the protective properties of NAT are not something that are not normally depended on by themselves to defend a network and with the vastly enlarged IPv6 address scope there is no longer a need to amplify the available addresses. However, the desire to have internal address control still exists. The most common reason for using NAT66 is likely to be the maintaining of the existing address scheme of the internal network despite changes outside of it. Imagine that you have an internal network of 2000 IP addresses and one day the company changes its ISP and thus the addresses assigned to it. Even if most of the addressing is handled by DHCP, changing the address scheme is going to have an impact on operations.

Addressing stability can be achieved by:

- Keeping the same provider - this would depend on the reason for the change. If the cost of this provider has become too expensive this is unlikely. If the ISP is out of business it becomes impossible.
- Transfer the addresses from the old provider to the new one - There is little motivation for an ISP to do you a favor for not doing business with them.
- Get your own autonomous system number - this can be too expensive for smaller organizations.
- NAT - this is the only one on the list that is in the control of IT.

There are differences between NAT66 and IPv4 NAT. Because there is no shortage of addresses most organizations will be given a /48 network that can be translated into another /48 network. This allows for a one to one translation, no need for port forwarding. This is a good thing because port forwarding is more complicated in IPv6. In fact, NAT66 will actually just be the rewriting of the prefix on the address.

## Example

If your current IPv6 address is

```
2001:db8:cafe::/48
```

you could change it to

```
2001:db8:fea7::/48
```

There is an exception to the one to one translation. NAT66 cannot translate internal networks that contain 0xffff in bits 49 through 63 - this is due to the way checksums are calculated in TCP/IP: they use the one's-complement representation of numbers which assigns the value zero to both 0x0000 and 0xffff.

## How FortiOS differentiates sessions when NATing

The basics of NAT are fairly simple. Many private addresses get translated into a smaller number of public addresses, often just one. The trick is how the FortiGate keeps track of the return traffic because the web server, or what ever device that was out on the Internet is going to be sending traffic back not to the private address behind the FortiGate but to the IP address of the interface on the public side of the FortiGate.

The way this is done is by making each session unique. Most of the attributes that are available in the network packets cannot be changed without changing where the packet will go but because the source port has to be changed anyway in case two computer on the network used the same source port this is a useful way of making each listing of network attributes a unique combination. As a packet goes through the NAT process FortiOS assigns different source ports for each of the internally initiated sessions and keeping track of which port was used for each device in a database until the session has ended. It then becomes a matter of how the port number is selected.

In a very simple example of an environment using NAT, we will use a fictitious university with a rather large student population. So large in fact that they use a subnet of 10.0.0.0/8 as their subnet for workstation IP addresses. All of these private IP addresses are NATed out a single IP address. To keep the number of numeric values in this example from getting to a confusing level, we'll just us "u.u.u.1" to refer to the public IP address of the University and the IP address of the web server on the Internet will be "w.w.w.1".

Student A (IP address 10.1.1.56) sends an HTML request to a web server on the Internet with the IP address w.w.w.1. The applicable networking information in the packet breaks down as follows:

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.1.1.56	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Source port or src-port:	10000	<b>46372</b>
Destination port or dst-port	80	80

The source IP address is now that of the public facing interface of the FortiGate and source port number is an unused TCP port number on the FortiGate chosen by the FortiGate. Of these variable the only one the that FortiGate can really change and still have the packet reach the correct destination, in both directions, is the source port number.

There are a few methods of assigning the port number. First we'll look at the methods that are or have been used in the industry but aren't used by Fortinet.

### Global pool

This method of differentiation focuses on the attribute of the source port number. In this approach a single pool of potential port numbers is set aside for the purposes of NAT. As a pool number is assigned, it is removed from the pool so that two sessions from different computers can not using the same port number. Once the session is over and no longer in use by the computer, the port number is put back into the pool where it can be assigned again.

#### Example global pool:

	Hexidecimal	Decimal
Start or range	0x7000	28672
End end of range	0xF000	61440
Possible ports in range	215	32768

This is a simple approach to implement and is good if the number of connections in unlike to reach the pool size. It would be okay for home use, but our example is for a university using 10.1.1.0/8 as a subnet. That means 16,777,214 possible IP addresses; more than this method can handle.

Fortinet does not use this method.

### Global per protocol

This method uses the attributes source port number and type of protocol to differentiate between sessions. This approach is a variation of the first one. An additional piece of information is referred to in the packet that describes the protocol. For instance UDP or TCP. This could effectively double the number of potential addresses to NAT.

#### Example:

Here are two possible packets that would be considered different by the FortiGate so that any responses from the web server would make it back to their correct original sender.

#### From Student A

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.1.1.56	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	tcp	tcp
Source port or src-port:	10000	<b>46372</b>
Destination port or dst-port	80	80

**From Student B**

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.5.1.233	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	udp	udp
Source port or src-port:	26785	<b>46372</b>
Destination port or dst-port	80	80

Even though the source port is the same, because the protocol is different they are considered to be from different sessions and different computers.

The drawback is that it would depend on the protocols being used be evenly distributed between TCP and UDP. Even if this was the case the number would only double; reaching an upper limit of 65,536 possible connections. That number is still far short of the possible more than 16 million for an IP subnet with an eight bit subnet mask like the one in our example.

Fortinet does not use this method.

**Per NAT IP Pool**

This approach adds on to the previous one by adding another variable. In this case that variable is the IP addresses on the public side of the FortiGate. By having a pool of IP addresses to assign as the source IP address when NATing, the same number that was potentially available for the Global per protocol method can be multiplied by the number of external IP addresses in the pool. If you can assign a second IP address to the pool, you can double the potential number of sessions.

**Example:**

In this example it will be assumed that the FortiGate has 2 IP addresses that it can use. This could happen either by using two ISPs, or by having a pool of IP addresses assigned to a single interface. For simplicity will refer to these IP public IP addresses as u.u.u.1 and u.u.u.2.

Here are two possible packets that would be considered different by the FortiGate so that any responses from the web server would make it back to their correct original sender.

**From Student A**

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.1.1.56	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	tcp	tcp

Attribute	Original Packet	Packet after NATing
Source port or src-port:	10000	<b>46372</b>
Destination port or dst-port	80	80

### From Student B

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.5.1.233	u.u.u.2
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	tcp	tcp
Source port or src-port:	26785	<b>46372</b>
Destination port or dst-port	80	80

In this example we even made the protocol the same. After the NATing process all of the variables are the same except the source address. This is still going to make it back to the original sender.

The drawback is that if you have only one IP address for the purposes of NATing this method does not gain you anything over the last method. Or if you do have multiple IP addresses to use it will still take quite a few to reach the 16 million possible that the subnet is capable of handling.

Fortinet does not use this method.

### Per NAT IP, destination IP, port, and protocol

#### This is the approach that FortiOS uses.

It uses all of the differentiation point of the previous methods, NAT IP, port number and protocol, but the additional information point of the destination IP is also used. So now the network information points in the packet that the FortiGate keeps in its database to differentiate between sessions is:

- Public IP address of the FortiGate assigned by NATing
- Protocol of the traffic
- Source port assigned by the FortiGate
- Destination IP address of the packet

The last one is an especially good way to differentiate because as a theoretical number, the upper limit on that is the numbers of Public IP addresses on the whole of the Internet. Chances are that while a large number of session from inside the University will be going to a small group of sites such as Google, Youtube, Facebook and some others it is unlikely that they will all be going to them at the same time.

**Example:**

In this example it will be assumed that the FortiGate has only one IP address. Two possible packets will be described. The only difference in the attributes recorded will be the destination of the HTML request. These packets are still considered to be from different sessions and any responses will make it back to the correct computer.

**From Student A**

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.1.1.56	u.u.u.1
Destination IP address or dst-ip:	w.w.w.1	w.w.w.1
Protocol	tcp	tcp
Source port or src-port:	10000	<b>46372</b>
Destination port or dst-port	80	80

**From Student B**

Attribute	Original Packet	Packet after NATing
Source IP address or src-ip	10.5.1.233	u.u.u.1
Destination IP address or dst-ip:	w.w.w.2	w.w.w.2
Protocol	tcp	tcp
Source port or src-port:	26785	<b>46372</b>
Destination port or dst-port	80	80

The reason that these attributes are used to determine differentiation between traffic is based on how the indexes for the sessions are recorded in the database. When a TCP connection is made through a FortiGate unit, a session is created and two indexes are created for the session. The FortiGate unit uses these indexes to guide matching traffic to the session.

This following could be the session record for the TCP connection in the first example.

Attribute	Outgoing Traffic	Returning Traffic
Source IP address	10.78.33.97 (internal address)	w.w.w.1
Destination address	w.w.w.1	u.u.u.1

Attribute	Outgoing Traffic	Returning Traffic
Protocol	tcp	tcp
Source port	10000 (from original computer) 46372 (assigned by NAT)	80
Destination port	80	46372 (FortiGate assigned port)

Using the FortiGate's approach for session differentiation, FortiOS only has to ensure that the assigned port, along with the other four attributes is a unique combination to identify the session. So for example, if Student A simultaneously makes a HTTP(port 80) connection and a HTTPS(port 443) connection the same web server this would create another session and the index in the reply direction would be:

Attribute	Outgoing Traffic	Returning Traffic
Source IP address	10.78.33.97 (internal address)	w.w.w.1
Destination address	w.w.w.1	u.u.u.1
Protocol	tcp	tcp
Source port	10000 (from original computer) 46372 (assigned by NAT)	443
Destination port	443	46372 (FortiGate assigned port)

These two sessions are different and acceptable because of the different source port numbers on the returning traffic or the destination port depending on the direction of the traffic.

### Calculations for possible session numbers

The result of using these four attributes instead of just the one that was originally used is a large increase in the number of possible unique combinations. For those who love math, the maximum number of simultaneous connections that can be supported is:

$$N \times R \times P \times D \times Dp$$

where:

- **N** is the number of NAT IP addresses
- **R** is the port range,
- **P** is the number of protocols,
- **D** is the number of unique destination IP addresses
- **Dp** the number of unique destination ports.

As a rough example let's do some basic calculations

- N - In our existing example we have already stated that there is only one public IP address that is being used by NAT. Realistically, for a university this number would likely be larger, but we're keeping it simple.

$$N = 1$$

R - The port range for our example has already been describe and we will keep it the same.

$$R = 32768$$

P - While there are a few protocols that are involved in Internet traffic we will limit this calculation just to TCP traffic.

$$P = 1$$

D - As mentioned before the number of unique destination addresses is growing larger every day, so figuring out the upper limit of that number would be difficult to say the least. Instead we will make the assumption that most of the university students, do to their shared interest and similar demographic will concentrate most of their web browsing to the same sites; sites such as YouTube, Facebook, Google, Twitter, Instagram, Wikipedia etc. This is not even taking into account the fact that many of these popular sites use load balancing and multiple IP addresses. As an arbitrary number let's use the number 25.

$$D = 25$$

Dp - To keep things simple it is tempting to limit the destination port to port 80, the one that many associate with web browsing, but this would not be realistic. the use of HTTPS, port 443 is on the rise. There is also email, DNS, FTP, NTP and a number of other background services that we use without thinking too closely about. Let's keep it small and say ten of them.

$$Dp = 10$$

The math on this very conservative calculation is:

$$1 \times 32768 \times 1 \times 25 \times 10 = 8,192,000 \text{ possible NAT sessions}$$

When you take into account that the chances of everybody being online at the same time, going only to one of those 25 sites and not millions of others, and using only TCP not UDP or any of the other protocols, it starts to look like this method may provide enough potential unique sessions even for a subnet as large as the one described.

## IP Pools

IP Pools are a mechanism that allow sessions leaving the FortiGate Firewall to use NAT. An IP pool defines a single IP address or a range of IP addresses to be used as the source address for the duration of the session. These assigned addresses will be used instead of the IP address assigned to that FortiGate interface.

When using IP pools for NATing, there is a limitation that must be taken into account. In order for communication to be successful in both directions, it is normal for the source address in the packet header assigned by the NAT process to be an address that is associated with the interface that the traffic is going through. For example, if traffic is going out an interface with the IP address 172.16.100.1, packets would be NATed so that the source IP address would be 172.16.100.1. This way the returning traffic will be directed to the same interface on the same FortiGate that the traffic left from. Even if the packets are assigned a source address that is associated with another interface on the same FortiGate this can cause issues with asymmetrical routing. It is possible to configure the NATed source IP address to be different than the IP address of the interface but you have to make sure that the routing rules of the surrounding network devices take this unorthodox approach into consideration.

There are 4 types of IP Pools that can be configured on the FortiGate firewall:

- One-to-One - in this case the only internal address used by the external address is the internal address that it is mapped to.
- Overload - this is the default setting. Internal addresses other than the one designated in the policy can use this address for the purposes of NAT.
- Fixed Port Range - rather than a single address to be used, there is a range of addresses that can be used as the NAT address. These addresses are randomly assigned as the connections are made.
- Port Block Allocation - this setting is used to allocate a block of port numbers for IP pool users. Two variables will also have to be set. The block size can be set from 64 to 4096 and as the name implies describes the number of ports in one block of port numbers. The number of blocks per user determines how many of these blocks will be assigned. This number can range from 1 to 128.

Be careful when calculating the values of the variables. The maximum number of ports that are available on an address is 65,536. If you chose the maximum value for both variables you will get a number far in excess of the available port numbers.

$$4096 \times 128 = 524,288$$

One of the more common examples is when you have an email server behind your FortiGate firewall and the range of IP addresses assigned to you by your ISP is more than one. If an organization is assigned multiple IP addresses it is normally considered a best practice to assign a specific address other than the one used for the Firewall to the mail server. However, when normal NAT is used the address assigned to the firewall is also assigned to any outbound sessions. Anti-spam services match the source IP address of mail traffic that they receive to the MX record on DNS servers as an indicator for spam. If there is a mismatch the mail may not get through so there is a need to make sure that the NATed address assigned matches the MX record.

You can also use the Central NAT table as a way to configure IP pools.

### Source IP address and IP pool address matching when using a range

When the source addresses are translated to an IP pool that is a range of addresses, one of the following three cases may occur:

#### Scenario 1:

The number of source addresses equals that of IP pool addresses

In this case, the FortiGate unit always matches the IP addressed one to one.

If you enable fixed port in such a case, the FortiGate unit preserves the original source port. This may cause conflicts if more than one security policy uses the same IP pool, or the same IP addresses are used in more than one IP pool.

### Scenario 2:

The number of source addresses is more than that of IP pool addresses

In this case, the FortiGate unit translates IP addresses using a wrap-around mechanism. If you enable fixed port in such a case, the FortiGate unit preserves the original source port. But conflicts may occur since users may have different sessions using the same TCP 5 tuples.

### Scenario 3:

The number of source addresses is fewer than that of IP pool addresses

In this case, some of the IP pool addresses are used and the rest of them are not be used.

## ARP Replies

If a FortiGate firewall interface IP address overlaps with one or more IP pool address ranges, the interface responds to ARP requests for all of the IP addresses in the overlapping IP pools. For example, consider a FortiGate unit with the following IP addresses for the port1 and port2 interfaces:

- port1 IP address: 1.1.1.1/255.255.255.0 (range is 1.1.1.0-1.1.1.255)
- port2 IP address: 2.2.2.2/255.255.255.0 (range is 2.2.2.0-2.2.2.255)

And the following IP pools:

- IP\_pool\_1: 1.1.1.10-1.1.1.20
- IP\_pool\_2: 2.2.2.10-2.2.2.20
- IP\_pool\_3: 2.2.2.30-2.2.2.40

The port1 interface overlap IP range with IP\_pool\_1 is:

$(1.1.1.0-1.1.1.255) \text{ and } (1.1.1.10-1.1.1.20) = 1.1.1.10-1.1.1.20$

The port2 interface overlap IP range with IP\_pool\_2 is:

$(2.2.2.0-2.2.2.255) \text{ \& } (2.2.2.10-2.2.2.20) = 2.2.2.10-2.2.2.20$

The port2 interface overlap IP range with IP\_pool\_3 is:

$(2.2.2.0-2.2.2.255) \text{ \& } (2.2.2.30-2.2.2.40) = 2.2.2.30-2.2.2.40$

And the result is:

- The port1 interface answers ARP requests for 1.1.1.10-1.1.1.20
- The port2 interface answers ARP requests for 2.2.2.10-2.2.2.20 and for 2.2.2.30-2.2.2.40

Select Enable NAT in a security policy and then select Dynamic IP Pool. Select an IP pool to translate the source address of packets leaving the FortiGate unit to an address randomly selected from the IP pool. Whether or not the external address of an IP Pool will respond to an ARP request can be disabled. You might want to disable the ability to responded to ARP requests so that these address cannot be used as a way into your network or show up on a port scan.

## IP pools and zones

Because IP pools are associated with individual interfaces IP pools cannot be set up for a zone. IP pools are connected to individual interfaces.

## Fixed Port

Some network configurations do not operate correctly if a NAT policy translates the source port of packets used by the connection. NAT translates source ports to keep track of connections for a particular service.

However, enabling the use of a fixed port means that only one connection can be supported through the firewall for this service. To be able to support multiple connections, add an IP pool, and then select Dynamic IP pool in the policy. The firewall randomly selects an IP address from the IP pool and assigns it to each connection. In this case, the number of connections that the firewall can support is limited by the number of IP addresses in the IP pool.

## Match-VIP

The match-vip feature allows the FortiGate unit to log virtual IP traffic that gets implicitly dropped. This feature eliminates the need to create two policies for virtual IPs; one that allows the virtual IP, and the other to get proper log entry for DROP rules.

For example, you have a virtual IP security policy and enabled the match-vip feature; the virtual IP traffic that is not matched by the policy is now caught.

The match-vip feature is available only in the CLI. By default, the feature is disabled.

## Services and TCP ports

There are a number of different services and protocols in use on the Internet. The most commonly known is HTTP which is used by web servers to transmit requests and responses for unencrypted web pages. These services are set up to listen for requests on a numbered port. These services and protocols can use any port from 1 to 65,535. To keep things simple for everyone a large number of the more commonly used services started using a standardized list of ports. For instance, though it is not required, by default, most web servers listen for HTTP requests on port 80 and by default, web browsers will send HTTP traffic to port 80. If you wish to use another port such as 8080 you would put “:8080” at the end of the URL to indicate that you want the browser to use 8080 instead of the default port.

### Example

Default URL for HTTP traffic when the web server is listening on the standard HTTP port:

`http://fortinet.com`

URL to the same address when the web server is listening for HTTP traffic on port 8080

`http://fortinet.com:8080`

Services represent typical traffic types and application packets that pass through the FortiGate unit. Firewall services define one or more protocols and port numbers associated with each service. Security policies use service definitions to match session types. You can organize related services into service groups to simplify your security policy list.

Many well-known traffic types have been predefined on the FortiGate unit. If there is a service that does not appear on the list you can create a service or edit an existing one. You need to know the ports, IP addresses or protocols of that particular service or application uses, to create a service.

#### Best Practices

While you can edit a predefined service it is best to leave those ones alone and create a new service and name it something similar such as the same service name with a descriptive identifier appended.

Based on the previous example, instead of the name “HTTP” you could name the service “HTTP8080” or use the application that is using that port, “HTTP-Application”.

## Protocol Types

One of the fundamental aspects of a service is the type of protocol that use used to define it. When a service is defined one of the following categories of protocol needs to be determined:

- TCP/UDP/SCTP
- ICMP
- ICMPv6
- IP

Depending on which of these protocol categories is choose another set of specifications will can also be defined.

Protocol Type	Related specifications
TCP/UDP/SCTP	This is the most commonly used service protocol category. Once this category has been selected the other available options to choose are an address, either IP or FQDN, and the protocol and port number. The protocol will be TCP, UDP or SCTP.
ICMP or ICMP6	When ICMP or ICMP6 is chosen the available options are the ICMP Type and its code.
IP	When IP is the chosen protocol type the addition option is the Protocol Number.

## TCP/UDP/SCTP

### TCP

Transmission Control Protocol (TCP) is one of the core or fundamental protocols of the Internet. It is part of the Transport Layer of the OSI Model. It is designed to provide reliable delivery of data from a program on one device on the network or Internet to another program on another device on the network or Internet. TCP achieves its reliability because it is a connection based protocol. TCP is stream-oriented. It transports streams of data reliably and in order.

TCP establishes a prior connection link between the hosts before sending data. This is often referred to as the handshake. Once the link is established the protocol uses checks to verify that the data transmitted. If an error check fails the data is retransmitted. This makes sure that the data is getting to the destination error free and in the correct order so that it can be put back together into a form that is identical to the way they were sent.

TCP is configured more for reliability than for speed and because of this TCP will likely be slower than a connectionless protocol such as UDP. This is why TCP is generally not used for real time applications such as voice communication or online gaming.

Some of the applications that use TCP are:

- World Wide Web (HTTP and HTTPS)
- Email (SMTP, POP3, IMAP4)
- Remote administration (RDP)
- File transfer (FTP)

## UDP

User Datagram Protocol (UDP) like TCP is one of the core protocols of the Internet and part of the Transport Layer of the OSI Model. UDP is designed more for speed than reliability and is generally used for different applications than TCP. UDP sends messages, referred to as datagrams across the network or Internet to other hosts without establishing a prior communication link. In other words, there is no handshake.

UDP is an unreliable service as the datagrams can arrive out of order, duplicated or go missing without any mechanism to verify them. UDP works on the assumption that any error checking is done by the application or is not necessary for the function of the application. This way it avoids the overhead that is required to verify the integrity of the data.

This lack of overhead improves the speed of the data transfer and is why UDP is often used by applications that are time sensitive in nature. UDP's stateless nature is also great for applications that answer a large number of small queries from a large number of clients.

Common uses for UDP are:

- Domain Name Resolution (DNS)
- Time (NTP)
- Streaming media (RTSP, RTP and RTCP)
- Telephone of the Internet (VoIP)
- File Transfer (TFTP)
- Logging (SNMP)
- Online games (GTP and OGP)

## SCTP

Stream Control Transmission Protocol (SCTP) is part of the Transport Layer of the OSI Model just like TCP and UDP and provides some of the features of both of those protocols. It is message or datagram orientated like UDP but it also ensures reliable sequential transport of data with congestion control like TCP.

SCTP provides the following services:

- Acknowledged error-free non-duplicated transfer of user data
- Data fragmentation to conform to discovered path MTU size
- Sequenced delivery of user messages within multiple streams, with an option for order-of-arrival delivery of individual user messages
- Optional bundling of multiple user messages into a single SCTP packet
- Network-level fault tolerance through supporting of multi-homing at either or both ends of an association
- Congestion avoidance behavior and resistance to flooding and masquerade attacks

SCTP uses multi-streaming to transport its messages which means that there can be several independent streams of messages traveling in parallel between the points of the transmission. The data is sent out in larger chunks of data than is used by TCP just like UDP but the messages include a sequence number within each message in the same way that TCP does so that the data can be reassembled at the other end of the transmission in the correct sequence without the data having to arrive in the correct sequence.

SCTP is effective as the transport protocol for applications that require monitoring and session-loss detection. For such applications, the SCTP path and session failure detection mechanisms actively monitor the connectivity of the session. SCTP differs from TCP in having multi-homing capabilities at either or both ends and several streams within a connection, typically referred to as an association. A TCP stream represents a sequence of bytes; an SCTP stream represents a sequence of messages.

Some common applications of SCTP include supporting transmission of the following protocols over IP networks:

- SCTP is important in 3G and 4G/LTE networks (for example, HomeNodeB = FemtoCells)
- SS7 over IP (for example, for 3G mobile networks)
- SCTP is also defined and used for SIP over SCTP and H.248 over SCTP
- Transport of Public Switched Telephone Network (PSTN) signaling messages over IP networks.

SCTP is a much newer protocol. It was defined by the IETF Signaling Transport (SIGTRAN) working group in 2000. It was introduced by RFC 3286 and more fully define by RFC 4960.

The FortiGate firewall can apply security policies to SCTP sessions in the same way as TCP and UDP sessions. You can create security policies that accept or deny SCTP traffic by setting the service to "ALL". FortiOS does not include pre-defined SCTP services. To configure security policies for traffic with specific SCTP source or destination ports you must create custom firewall services for SCTP.

FortiGate units route SCTP traffic in the same way as TCP and UDP traffic. You can configure policy routes specifically for routing SCTP traffic by setting the protocol number to 132. SCTP policy routes can route SCTP traffic according to the destination port of the traffic if you add a port range to the policy route.

You can configure a FortiGate unit to perform stateful inspection of different types of SCTP traffic by creating custom SCTP services and defining the port numbers or port ranges used by those services. FortiGate units support SCTP over IPv4. The FortiGate unit performs the following checks on SCTP packets:

- Source and Destination Port and Verification Tag.
- Chunk Type, Chunk Flags and Chunk Length
- Verify that association exists
- Sequence of Chunk Types (INIT, INIT ACK, etc)
- Timer checking
- Four way handshake checking
- Heartbeat mechanism
- Protection against INIT/ACK flood DoS attacks, and long-INIT flooding
- Protection against association hijacking

FortiOS also supports SCTP sessions over IPsec VPN tunnels, as well as full traffic and event logging for SCTP sessions.

### Protocol Port Values

The source and destination ports for TCP/UDP/SCTP services are important to get correct. If they are reversed the service will not work. The destination port(s) are the ones that refer to the ports that the computer will be listening on. These are the port numbers that most people are familiar with when they associate a port number to

a protocol. In most cases the source port will be one that is randomly assigned by the computer that is not being already used by another service.

Most people associate HTTP with port 80. This means that a web-server will be listening on port 80 for any http requests being sent to the computer. The computer that is sending the request can use any port that is not already assigned to another service or communication session. There are 65,535 ports that it can randomly assign, but because the ports from 1 to 1024 are normally used for listening for incoming communications it is usually not in that range. It is unless there is a specific instance when you know that a communication will be coming from a predefined source port it is best practice to set the source port range from 1 to 65,535.

## ICMP

The Internet Control Message Protocol (ICMP) is a protocol layered onto the Internet Protocol Suite to provide error reporting flow control and first-hop gateway redirection. It is normally used by the operating systems of networked computers to send connectivity status query, response and error messages. It is assigned protocol number 1. There is a separate version of the protocol for both IPv4 and for IPv6. It is not designed to be absolutely reliable like TCP.

ICMP is not typically used for transporting data or for end-user network applications with the exception of some diagnostic utilities such as ping and traceroute.

ICMP messages are sent in several situations, for example:

- when a datagram cannot reach its destination,
- time exceeded messages
- redirect messages
- when the gateway does not have the buffering capacity to forward a datagram
- when the gateway can direct the host to send traffic on a shorter route.

Some of the specific ICMP message types are:

- ICMP\_ECHO
- ICMP\_TIMESTAMP
- ICMP\_INFO\_REQUEST
- ICMP\_ADDRESS

For ICMP error messages, only those reporting an error for an existing session can pass through the firewall. The security policy will allow traffic to be routed, forwarded or denied. If allowed, the ICMP packets will start a new session. Only ICMP error messages of a corresponding security policy is available will be sent back to the source. Otherwise, the packet is dropped. That is, only ICMP packets for a corresponding security policy can traverse the FortiGate unit.

## ICMP Types and Codes

ICMP has a number of messages that are identified by the "Type" field. Some of these types have assigned "Code" fields as well. The table below shows the different types of ICMP Types with their associated codes if there are any.

**ICMP Types and Codes**

Type Number	Type Name	Optional Code(s)
0	Echo Reply	
1	Unassigned	
2	Unassigned	
3	Destination Unreachable	0 Net Unreachable
		1 Host Unreachable
		2 Protocol Unreachable
		3 Port Unreachable
		4 Fragmentation Needed and Don't Fragment was Set
		5 Source Route Failed
		6 Destination Network Unknown
		7 Destination Host Unknown
		8 Source Host Isolated
		9 Communication with Destination Network is Administratively Prohibited
		10 Communication with Destination Host is Administratively Prohibited
		11 Destination Network Unreachable for Type of Service
		12 Destination Host Unreachable for Type of Service
		13 Communication Administratively Prohibited
		14 Host Precedence Violation
		15 Precedence cutoff in effect
4	Source Quench	

Type Number	Type Name	Optional Code(s)
5	Redirect	0 Redirect Datagram for the Network (or subnet)
		1 Redirect Datagram for the Host
		2 Redirect Datagram for the Type of Service and Network
		3 Redirect Datagram for the Type of Service and Host
6	Alternate Host Address	
7	Unassigned	
8	Echo	
9	Router Advertisement	
10	Router Selection	
11	Time Exceeded	0 Time to Live exceeded in Transit
		1 Fragment Reassembly Time Exceeded
12	Parameter Problem	0 Pointer indicates the error
		1 Missing a Required Option
		2 Bad Length
13	Timestamp	
14	Timestamp Reply	
15	Information Request	
16	Information Reply	
17	Address Mask Request	
18	Address Mask Reply	
19	Reserved (for Security)	

Type Number	Type Name	Optional Code(s)
20 - 29	Reserved (for Robustness Experiment)	
30	Traceroute	
31	Datagram Conversion Error	
32	Mobile Host Redirect	
33	IPv6 Where-Are-You	
34	IPv6 I-Am-Here	
35	Mobile Registration	
36	Mobile Registration Reply	
37	Domain Name Request	
38	Domain Name Reply	
39	SKIP	
40	Photuris	
41 - 255	Reserved	

### log-invalid-packet

The `log-invalid-packet` CLI setting is one that is intended to log invalid ICMP packets. The exact definition being:

If the FortiGate unit receives an ICMP error packet that contains an embedded `IP(A, B) | TCP(C, D)` header, then if FortiOS can locate the A:C -> B:D session it checks to make sure that the sequence number in the TCP header is within the range recorded in the session. If the sequence number is not in range then the ICMP packet is dropped.

When this field is enabled, the FortiGate also log messages that are not ICMP error packets.

**Types of logs covered by `log-invalid-packet`**

- Invalid ICMP
  - If ICMP error message verification (see "check-reset-range") is enabled
- Invalid DNS packets
  - DNS packets that contain requests for non-existing domains
- `iprope` check failed
- reverse path check fail
- denied and broadcast traffic
- no session matched

Some other examples of messages that are not errors that will be logged, based on [RFC792](#):

Type 3 messages correspond to "Destination Unreachable Message"

- Type 3, Code 1 = host unreachable
- Type 3, Code 3 = port unreachable

Type 11 messages correspond to "Time Exceeded Message"

- Type 11, Code 0 = time to live exceeded in transit

**ICMPv6**

Internet Control Message Protocol version 6 (ICMPv6) is the new implementation of the Internet Control Message Protocol (ICMP) that is part of Internet Protocol version 6 (IPv6). The ICMPv6 protocol is defined in [RFC 4443](#).

ICMPv6 is a multipurpose protocol. It performs such things as:

- error reporting in packet processing
- diagnostic functions
- Neighbor Discovery process
- IPv6 multicast membership reporting

It also designed as a framework to use extensions for use with future implementations and changes.

Examples of extensions that have already been written for ICMPv6:

- Neighbor Discovery Protocol (NDP) - a node discovery protocol in IPv6 which replaces and enhances functions of ARP.
- Secure Neighbor Discovery Protocol (SEND) - an extension of NDP with extra security.
- Multicast Router Discovery (MRD) - allows discovery of multicast routers.

ICMPv6 messages use IPv6 packets for transportation and can include IPv6 extension headers. ICMPv6 includes some of the functionality that in IPv4 was distributed among protocols such as ICMPv4, ARP (Address Resolution Protocol), and IGMP (Internet Group Membership Protocol version 3).

ICMPv6 has simplified the communication process by eliminating obsolete messages.

ICMPv6 messages are subdivided into two classes: error messages and information messages.

Error Messages are divided into four categories:

1. Destination Unreachable
2. Time Exceeded

3. Packet Too Big
4. Parameter Problems

Information messages are divided into three groups:

1. Diagnostic messages
2. Neighbor Discovery messages
3. Messages for the management of multicast groups.

### ICMPv6 Types and Codes

ICMPv6 has a number of messages that are identified by the “Type” field. Some of these types have assigned “Code” fields as well. The table below shows the different types of ICMP Types with their associated codes if there are any.

Type codes 0 – 127 are error messages and type codes 128 – 255 are for information messages.

#### ICMPv6 Types and Codes

Type Number	Type Name	Code
0	Reserved	0 - no route to destination
		1 - communication with destination administratively prohibited
		2 - beyond scope of source address
		3 - address unreachable
		4 - port unreachable
		5 - source address failed ingress/egress policy
		6 - reject route to destination
		7 - Error in Source Routing Header
1	Destination Unreachable	
2	Packet Too Big	
3	Time Exceeded	0 - hop limit exceeded in transit
		1 - fragment reassembly time exceeded
4	Parameter Problem	0 - erroneous header field encountered
		1 - unrecognized Next Header type encountered
		2 - unrecognized IPv6 option encountered

Type Number	Type Name	Code
<b>100</b>	Private Experimentation	
<b>101</b>	Private Experimentation	
<b>102 - 126</b>	Unassigned	
<b>127</b>	Reserved for expansion if ICMPv6 error messages	
<b>128</b>	Echo Request	
<b>129</b>	Echo Replay	
<b>130</b>	Multicast Listener Query	
<b>131</b>	Multicast Listener Report	
<b>132</b>	Multicast Listener Done	
<b>133</b>	Router Solicitation	
<b>134</b>	Router Advertisement	
<b>135</b>	Neighbor Solicitation	
<b>136</b>	Neighbor Advertisement	
<b>137</b>	Redirect Message	
<b>138</b>	Router Renumbering	0 - Router Renumbering Command
		1 - Router Renumbering Result
		255 - Sequence Number Reset

Type Number	Type Name	Code
139	ICMP Node Information Query	0 - The Data field contains an IPv6 address which is the Subject of this Query.
		1 - The Data field contains a name which is the Subject of this Query, or is empty, as in the case of a NOOP.
		2 - The Data field contains an IPv4 address which is the Subject of this Query.
140	ICMP Node Information Response	0 - A successful reply. The Reply Data field may or may not be empty.
		1 - The Responder refuses to supply the answer. The Reply Data field will be empty.
		2 - The Qtype of the Query is unknown to the Responder. The Reply Data field will be empty.
141	Inverse Neighbor Discovery Solicitation Message	
142	Inverse Neighbor Discovery Advertisement Message	
143	Version 2 Multicast Listener Report	
144	Home Agent Address Discovery Request Message	
145	Home Agent Address Discovery Reply Message	
146	Mobile Prefix Solicitation	
147	Mobile Prefix Advertisement	
148	Certification Path Solicitation Message	

Type Number	Type Name	Code
149	Certification Path Advertisement Message	
150	ICMP messages utilized by experimental mobility protocols such as Seamoby	
151	Multicast Router Advertisement	
152	Multicast Router Solicitation	
153	Multicast Router Termination	
154	FMIPv6 Messages	
155	RPL Control Message	
156	ILNPv6 Locator Update Message	
157	Duplicate Address Request	
158	Duplicate Address Confirmation	
159 – 199	Unassigned	
200	Private experimentation	
201	Private experimentation	
255	Reserved for expansion of ICMPv6 informational messages	

## IP

Internet Protocol (IP) is the primary part of the Network Layer of the OSI Model that is responsible for routing traffic across network boundaries. It is the protocol that is responsible for addressing. IPv4 is probable the version that most people are familiar with and it has been around since 1974. IPv6 is its current successor and due to a shortage of available IPv4 addresses compared to the explosive increase in the number of devices that use IP addresses, IPv6 is rapidly increasing in use.

When IP is chosen as the protocol type the available option to further specify the protocol is the protocol number. This is used to narrow down which protocol within the Internet Protocol Suite and provide a more granular control.

### Protocol Number

IP is responsible for more than the address that it is most commonly associated with and there are a number of associated protocols that make up the Network Layer. While there are not 256 of them, the field that identifies them is a numeric value between 0 and 256.

In the Internet Protocol version 4 (IPv4) [RFC791] there is a field called “Protocol” to identify the next level protocol. This is an 8 bit field. In Internet Protocol version 6 (IPv6) [RFC2460], this field is called the “Next Header” field.

### Protocol Numbers

#	Protocol	Protocol's Full Name
0	HOPOPT	IPv6 Hop-by-Hop Option
1	ICMP	Internet Control Message Protocol
2	IGMP	Internet Group Management
3	GGP	Gateway-to-Gateway
4	IPv4	IPv4 encapsulation Protocol
5	ST	Stream
6	TCP	Transmission Control Protocol
7	CBT	CBT
8	EGP	Exterior Gateway Protocol
9	IGP	Any private interior gateway (used by Cisco for their IGRP)
10	BBN-RCC-MON	BBN RCC Monitoring
11	NVP-II	Network Voice Protocol
12	PUP	PUP

#	Protocol	Protocol's Full Name
13	ARGUS	ARGUS
14	EMCON	EMCON

## VPN Policies

At one point, if you wanted to have secure digital communications between 2 points a private network would be created. This network would only allow the people that were intended to get the communications on it. This is very straightforward if the 2 points are in the same room or even in the same building. It can all be done physically. If you are supposed to be on the secure network

VPNs are an answer to one of today's biggest concerns, how to make digital communications secure between to points that must communicate over the Internet which anybody can have access to.

There are two types of VPNs supported by FortiOS, SSL and IPsec. They are differentiated by the security protocol suites that are used to secure the traffic. These are both described in more detail in the VPN section, but the IPsec VPN can be configured as an **Action** with a firewall policy.

## IPsec Policies

IPsec policies allow IPsec VPN traffic access to the internal network from a remote location. These policies include authentication information that authenticates users and user group or groups. These policies specify the following:

- the FortiGate firewall interface that provides the physical connection to the remote VPN gateway, usually an interface connected to the Internet
- the FortiGate firewall interface that connects to the private network
- IP addresses associated with data that has to be encrypted and decrypted
- optional: a schedule that restricts when the VPN can operate, and services (or types of data) that can be sent.

For a route-based (interface mode) VPN, you do not configure an IPsec security policy. Instead, you configure two regular ACCEPT security policies, one for each direction of communication, with the IPsec virtual interface as the source or destination interface, as appropriate.

## DSRI

The Disable Server Response Inspection (DSRI) options is available for configuration in the CLI. This is used to assist performance when only URL filtering is being used. This allows the system to ignore the HTTP server responses. The setting is configured to be disabled by default.

## CLI syntax for changing the status of the DSRI setting

### In IPv4 or IPv6 firewall policies

```
config firewall policy|policy6
edit 0
```

```
set dsri enable|disable
end
```

### In IPv4 or IPv6 interface policies

```
config firewall interface-policy|interface-policy6
edit 0
set dsri enable|disable
end
```

### When using the sniffer

```
config firewall sniffer
edit 0
set dsri enable|disable
end
```

## Interface Policies

Interface policies are implemented before the “security” policies and are only flow based. They are configured in the CLI.

This feature allows you to attach a set of IPS policies with the interface instead of the forwarding path, so packets can be delivered to IPS before entering firewall. This feature is used for following IPS deployments:

- One-Arm: by defining interface policies with IPS and DoS anomaly checks and enabling sniff-mode on the interface, the interface can be used for one-arm IDS;
- IPv6 IPS: IPS inspection can be enabled through interface IPv6 policy. Only IPS signature scan is supported in FortiOS 4.0. IPv6 DoS protection is not supported;
- Scan traffics that destined to FortiGate;
- Scan and log traffics that are silently dropped or flooded by Firewall or Multicast traffic.

IPS sensors can be assigned to an interface policy. Both incoming and outgoing packets are inspected by IPS sensor (signature).

Here is an example of an interface policy,

# show full-configuration

```
config firewall interface-policy
edit 1
set status enable
set comments 'test interface policy #1'
set logtraffic utm
set interface "port9"
set srcaddr "all"
set dstaddr "all"
set service "ALL"
set application-list-status disable
set ips-sensor-status disable
set dsri disable
set av-profile-status enable
set av-profile "default"
set webfilter-profile-status disable
set spamfilter-profile-status disable
set dlp-sensor-status disable
set scan-botnet-connections disable
```

```
next
end
```

## DoS Protection

Denial of Service (DoS) policies are primarily used to apply DoS anomaly checks to network traffic based on the FortiGate interface it is entering as well as the source and destination addresses. DoS checks are a traffic anomaly detection feature to identify network traffic that does not fit known or common traffic patterns and behavior. A common example of anomalous traffic is the denial of service attack. A denial of service occurs when an attacking system starts an abnormally large number of sessions with a target system. The large number of sessions slows down or disables the target system, so that legitimate users can no longer use it.

DoS policies are similar to firewall policies except that instead of defining the way traffic is allowed to flow, they keep track of certain traffic patterns and attributes and will stop traffic displaying those attributes. Further, DoS policies affect only incoming traffic on a single interface. You can further limit a DoS policy by source address, destination address, and service.

DoS configurations have been changed a couple of times in the past. In FortiOS 4.0, DoS protection is moved to the interface policy, so when it is enabled, it is the first thing checked when a packet enters FortiGate. Because of this early detection, DoS policies are a very efficient defense that uses few resources. Denial of service attacks, for example, are detected and its packets dropped before requiring security policy look-ups, antivirus scans, and other protective but resource-intensive operations.

A DoS policy examines network traffic arriving at an interface for anomalous patterns usually indicating an attack. This does not mean that all anomalies experience by the firewall are the result of an intentional attack.

Because an improperly configured DoS anomaly check can interfere with network traffic, no DoS checks are preconfigured on a factory default FortiGate unit. You must create your own before they will take effect. Thresholds for newly created sensors are preset with recommended values that you can adjust to meet the needs of your network.

To create a Denial of Service policy determine if it needs to be an IPv4 or IPv6 policy, then go to:

**Policy & Objects > IPv4 DoS Policy** for IPv4.

**Policy & Objects > IPv6 DoS Policy** for IPv6.

The **Enable SSH Deep Scan** feature is enabled by default when creating a new SSL/SSH Inspection profile. There are situations where this feature can cause issues so be sure that you would like it enabled before applying it.

### Settings used in configuring DoS

#### Incoming Interface

The interface to which this security policy applies. It will be the that the traffic is coming into the firewall on.

#### Source Address

This will be the address that the traffic is coming from and must be a address listed in the Address section of the Firewall Objects. This can include the predefined “all” address which covers any address coming in on any interface. Multiple addresses or address groups can be chosen

## Destination Address

This will be the address that the traffic is addressed to. In this case it must be an address that is associated with the firewall itself. For instance it could be one of the interface address of the firewall, a secondary IP address or the interface address assigned to a Virtual IP address. Just like with the Source Address this address must be already configured before being used in the DoS policy. Multiple addresses, virtual IPs or virtual IP groups can be chosen.

## Service

While the Service field allows for the use of the ALL service some administrators prefer to optimize the resources of the firewall and only check on the services that will be answered on an interface. Multiple services or service groups can be chosen.

## Anomalies

The anomalies can not be configured by the user. They are predefined sensors set up for specific patterns of anomalous traffic

The anomalies that have been predefined for use in the DoS Policies are:

Anomaly Name	Description	Recommended Threshold
<b>tcp_syn_flood</b>	If the SYN packet rate of new TCP connections, including retransmission, to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
<b>tcp_port_scan</b>	If the SYN packet rate of new TCP connections, including retransmission, from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second.
<b>tcp_src_session</b>	If the number of concurrent TCP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
<b>tcp_dst_session</b>	If the number of concurrent TCP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
<b>udp_flood</b>	If the UDP traffic to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
<b>udp_scan</b>	If the number of UDP sessions originating from one source IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.

Anomaly Name	Description	Recommended Threshold
<b>udp_src_session</b>	If the number of concurrent UDP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
<b>udp_dst_session</b>	If the number of concurrent UDP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
<b>icmp_flood</b>	If the number of ICMP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	250 packets per second.
<b>icmp_sweep</b>	If the number of ICMP packets originating from one source IP address exceeds the configured threshold value, the action is executed.	100 packets per second.
<b>icmp_src_session</b>	If the number of concurrent ICMP connections from one source IP address exceeds the configured threshold value, the action is executed.	300 concurrent sessions
<b>icmp_dst_session</b>	If the number of concurrent ICMP connections to one destination IP address exceeds the configured threshold value, the action is executed.	3000 concurrent sessions
<b>ip_src_session</b>	If the number of concurrent IP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
<b>ip_dst_session</b>	If the number of concurrent IP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
<b>sctp_flood</b>	If the number of SCTP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second
<b>sctp_scan</b>	If the number of SCTP sessions originating from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second
<b>sctp_src_session</b>	If the number of concurrent SCTP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions
<b>sctp_dst_session</b>	If the number of concurrent SCTP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions

## Status

The status field is enabled to enable the sensor for the associated anomaly. In terms of actions performed there is no difference between disabling a sensor and having the action as “Pass” but by disabling sensors that are not being used for blocking or logging you can save some resources of the firewall that can be better used elsewhere.

## Logging

Regardless of whether the traffic is blocked or passed through the anomalous traffic will be logged.

## Pass

Allows the anomalous traffic to pass through unimpeded.

## Block

For Thresholds based on the number of concurrent sessions blocking the anomaly will not allow more than the number of concurrent sessions set as the threshold.

For rate based thresholds where the threshold is measured in packets per second, the Action setting “Block” prevents the overwhelming of the firewall by anomalous traffic in one of 2 ways. Setting which of those 2 ways will be issued is determined in the CLI.

- continuous - blocks packets once an anomaly is detected. This overrides individual anomaly settings.
- periodical - allows matching anomalous traffic up to the rate set by the threshold.

If the period for a particular anomaly is 60 seconds, such as those where the threshold is measured in concurrent sessions, after the 60 second timer has expired, the number of allowed packets that match the anomaly criteria is reset to zero. This means that if you allow 10 sessions through before blocking, after the 60 seconds is up, another 10 will be allowed. The attrition of sessions from expiration should keep the allowed sessions from reaching the maximum.

To set the type of block action for the rate based anomaly sensors:

```
config ips global
    set anomaly-mode continuous
    set anomaly-mode periodical
end
```

## Threshold

The threshold can be either in terms of concurrent session or in packets per second depending on which sensor is being referred to.

## Quarantine

The quarantine feature is found in the CLI. This setting is used to block any further traffic from a source address that is now considered to be a malicious actor or a source of traffic dangerous to the network. Not only is no more traffic accepted for the duration of the quarantine through the DoS policy but the source IP address of the traffic is added to the banned source ip list. This list is kept in the kernel and used by

- Antivirus
- Data Leak Prevention (DLP)

- Denial of Service (DoS)
- Intrusion Prevention System (IPS)

Any policies that use any of these features will block traffic from the attacker's IP address.

### Syntax

```
config firewall {DoS-policy|DoS-policy6}
  edit <policyid>
    set quarantine {none|attacker}
    set quarantine-exipiry {string}
    set quarantine-log {enable|disable}
  end
```

Option	Description
<b>quarantine</b>	Quarantine method. <ul style="list-style-type: none"> <li>• <code>none</code> - Quarantine is disabled.</li> <li>• <code>attacker</code> - Block all traffic sent from the attacker's IP address. The quarantined IP address is also added to the banned ip list. The destination address is not affected.</li> </ul>
<b>quarantine-exipiry</b>	Duration of quarantine The format is <code>###d##h##m</code> , ranging from 1 minute to 364 days, 23 hours, and 59 minutes starting from now. The default is <code>0d0h5m</code> . Requires quarantine set to <code>attacker</code> .
<b>quarantine-log</b>	Enables or disables the logging of quarantine events.

### One-Arm IDS

Interface-based policy only defines what and how IPS functions are applied to the packets transmitted by the interface. It works no matter if the port is used in a forwarding path or used as an One-Arm device.

To enable One-Arm IDS, the user should first enable sniff-mode on the interface,

```
config system interface
  edit port2
    set ips-sniffer-mode enable
  next
end
```

Once sniff-mode is turned on, both incoming and outgoing packets will be dropped after IPS inspections. The port can be connected to a hub or a switch's SPAN port. Any packet picked up by the interface will still follow the interface policy so different IPS and DoS anomaly checks can be applied.

### IPv6 IPS

IPv6 IPS signature scan can be enabled by interface policy. The user can create an normal IPS sensor and assign it to the IPv6 interface policy.

```
config firewall interface-policy6
  edit 1
    set interface "port1"
```

```
set srcaddr6 "all"  
set dstaddr6 "all"  
set service6 "ANY"  
set ips-sensor-status enable  
set ips-sensor "all_default"  
next  
end
```

## Traffic Destined to the FortiGate unit

IPS enabled in firewall policies can only inspect the traffic pass through FortiGate unit, not the traffic destined to FortiGate unit. Enabling IPS in interface-policy allows IPS to pick up any packet on the interface so it is able to inspect attacks targeting FGT.

## Dropped, Flooded, Broadcast, Multicast and L2 packets

In many evaluation or certification tests, FortiGate firewall is often required to log any packets dropped by the firewall. In most of cases, these packets are of invalid headers so firewall just drops them silently. It is natural to forward all these packets to IPS first so FortiGate firewall is able to generate logs for invalid packets.

Flooded, broadcast and multicast traffics do not reach any of services in the forwarding path. They can be inspected by the interface policy as long as they match the addresses defined. Potentially, L2 packets can also be sent to IPS for inspection through interface-policy, but it is not enabled in FortiOS 4.0.

## GUI and CLI

Now in FortiGate, there are two places that IPS can be enabled, in a firewall policy and in an interface policy. In the firewall policy implementation, IPS sensor can be configured in both CLI and GUI. When adding an IPS sensor to an interface policy it must be done through the CLI. There is no GUI input window for the “Interface Policy”. There is however, a DoS Policy section in the GUI.

## Local-In Policies

On the FortiGate unit, there are a number of protocols and traffic that is specific to the internal workings of FortiOS. For many of these traffic sources, you can identify a specific port/IP address for this self-originating traffic. The following traffic can be configured to a specific port/IP address:

- SNMP
- Syslog
- alert email
- FortiManager connection IP
- FortiGuard services
- FortiAnalyzer logging
- NTP
- DNS
- Authorization requests such as RADIUS
- FSSO

Security policies control the flow of traffic through the FortiGate unit. The FortiGate unit also includes the option of controlling internal traffic, that is, management traffic.

Each interface includes an allow access configuration to allow management access for specific protocols. Local policies are set up automatically to allow all users all access. Local-in policies takes this a step further, to enable or restrict the user with that access. This also extends beyond the allow access selection.

Local-in policies are configured in the CLI with the commands:

```
config firewall local-in-policy
  edit <policy_number>
    set intf <source_interface>
    set srcaddr <source_address>
    set dstaddr <destination_address>
    set action {accept | deny}
    set service <service name>
    set schedule <schedule_name>
  end
```

For example, you can configure a local-in policy so that only administrators can access the FortiGate unit on weekends from a specific management computer at 192.168.21.12, represented by the address object mgmt-comp1, using SSH on port 3 (192.168.21.77 represented by the address object FG-port3) using the Weekend schedule which defines the time the of access.

```
config firewall local-in-policy
  edit <1>
    set intf port3
    set srcaddr mgmt-comp1
    set dstaddr FG-port3
    set action accept
    set service SSH
    set schedule Weekend
  end
```

You can also disable a policy should there be a requirement to turn off a policy for troubleshooting or other purpose. To disable a policy enter the commands:

```
config firewall local-in-policy
  edit <policy_number>
    set status disable
  end
```

Use the same commands with a status of enable to use the policy again.

It is also an option to dedicate the interface as HA management interface by using the setting:

```
set ha-mgmt-intf-only enable
```

Local-in policies are also supported for IPv6 by entering the command:

```
config firewall local-in-policy6.
```

While there is a section under **Policy & Objects** for viewing the existing **Local In Policy** configuration, policies cannot be created or edited here in the GUI. The Local In policies can only be created or edited in the CLI.

## Security Policy 0

Any security policy that is automatically added by the FortiGate unit has a policy ID number of zero (0). The most common reasons the FortiGate unit creates this policy is:

- The IPsec policy for FortiAnalyzer (and FortiManager version 3.0) is automatically added when an IPsec connection to the FortiAnalyzer unit or FortiManager is enabled.
- The policy to allow FortiGuard servers to be automatically added has a policy ID number of zero.
- The (default) drop rule that is the last rule in the policy and that is automatically added has a policy ID number of zero.
- When a network zone is defined within a VDOM, the intra-zone traffic set to allow or block is managed by policy 0 if it is not processed by a configured security policy.

This policy can appear in logs but will never appear in the security policy list, and therefore, can never be repositioned in the list.

When viewing the FortiGate firewall logs, you may find a log field entry indicating policyid=0. The following log message example indicates the log field policyid=0 in bold.

```
2008-10-06 00:13:49 log_id=0022013001 type=traffic subtype=violation pri=warning
vd=root SN=179089 duration=0 user=N/A group=N/A rule=0 policyid=0 proto=17
service=137/udp app_type=N/A status=deny src=10.181.77.73 srcname=10.181.77.73
dst=10.128.1.161 dstname=10.128.1.161 src_int=N/A dst_int="Internal" sent=0 rcvd=0
src_port=137 dst_port=137 vpn=N/A tran_ip=0.0.0.0 tran_port=0
```

## Deny Policies

Deny security policies deny traffic that is coming into the network. The FortiGate unit automatically blocks traffic that is associated with a deny security policy.

Deny security policies are usually configured when you need to restrict specific traffic, for example, SSH traffic. Deny security policies can also help when you want to block a service, such as DNS, but allow a specific DNS server.

## Accept Policies

Accept security policies accept traffic that is coming into the network. These policies allow traffic through the FortiGate unit, where the packets are scanned, translated if NAT is enabled, and then sent out to its destination.

Accept security policies are the most common security policies that are created in FortiOS. These security policies are basic policies, such as allowing Internet access, as well as complex policies, such as IPsec VPN.

## Fixed Port

Some network configurations do not operate correctly if a NAT policy translates the source port of packets used by the connection. NAT translates source ports to keep track of connections for a particular service.

From the CLI you can enable fixedport when configuring a security policy for NAT policies to prevent source port translation.

```
config firewall policy
  edit <policy-id>
    ...
    set fixedport enable
    ...
  end
```

However, enabling fixedport means that only one connection can be supported through the firewall for this service. To be able to support multiple connections, add an IP pool, and then select Dynamic IP pool in the policy.

The firewall randomly selects an IP address from the IP pool and assigns it to each connection. In this case, the number of connections that the firewall can support is limited by the number of IP addresses in the pool.

## Endpoint Security

Endpoint security enforces the use of the FortiClient End Point Security (FortiClient and FortiClient Lite) application on your network. It can also allow or deny endpoints access to the network based on the application installed on them.

By applying endpoint security to a security policy, you can enforce this type of security on your network. FortiClient enforcement can check that the endpoint is running the most recent version of the FortiClient application, that the antivirus signatures are up-to-date, and that the firewall is enabled. An endpoint is usually often a single PC with a single IP address being used to access network services through a FortiGate unit.

With endpoint security enabled on a policy, traffic that attempts to pass through, the FortiGate unit runs compliance checks on the originating host on the source interface. Non-compliant endpoints are blocked. If someone is browsing the web, the endpoints are redirected to a web portal which explains the non-compliance and provides a link to download the FortiClient application installer. The web portal is already installed on the FortiGate unit, as a replacement message, which you can modify if required.

Endpoint Security requires that all hosts using the security policy have the FortiClient Endpoint Security agent installed. Currently, FortiClient Endpoint Security is available for Microsoft Windows 2000 and later only.

For more information about endpoint security, see the Security Profiles chapter in the FortiOS Handbook.

## Traffic Logging

When you enable logging on a security policy, the FortiGate unit records the scanning process activity that occurs, as well as whether the FortiGate unit allowed or denied the traffic according to the rules stated in the security policy. This information can provide insight into whether a security policy is working properly, as well as if there needs to be any modifications to the security policy, such as adding traffic shaping for better traffic performance.

Depending on what the FortiGate unit has in the way of resources, there may be advantages in optimizing the amount of logging taking places. This is why in each policy you are given 3 options for the logging:

- **Disable Log Allowed Traffic** - Does not record any log messages about traffic accepted by this policy.

If you enable Log Allowed Traffic, the following two options are available:

- **Security Events** - This records only log messages relating to security events caused by traffic accepted by this policy.
- **All Sessions** - This records all log messages relating to all of the traffic accepted by this policy.

Depending on the model, if the Log all Sessions option is selected there may be 2 additional options. These options are normally available in the GUI on the higher end models such as the FortiGate 600C or larger.

- **Generate Logs when Session Starts**
- **Capture Packets**

You can also use the CLI to enter the following command to write a log message when a session starts:

```
config firewall policy
  edit <policy-index>
    set logtraffic-start
  end
```

Traffic is logged in the traffic log file and provides detailed information that you may not think you need, but do. For example, the traffic log can have information about an application used (web: HTTP.Image), and whether or not the packet was SNAT or DNAT translated. The following is an example of a traffic log message.

```
2011-04-13
05:23:47
log_id=4
type=traffic
subtype=other
pri=notice
vd=root
status="start"
src="10.41.101.20"
srcname="10.41.101.20"
src_port=58115

shaper_drop_sent=0
shaper_drop_rcvd=0
perip_drop=0
src_int="internal"
dst_int="wan1"
SN=97404 app="N/A"
app_cat="N/A"
carrier_ep="N/A"
```

If you want to know more about logging, see the Logging and Reporting chapter in the FortiOS Handbook. If you want to know more about traffic log messages, see the FortiGate Log Message Reference.

## Network defense

This section describes in general terms the means by which attackers can attempt to compromise your network using attacks at the network level rather than through application vulnerabilities, and steps you can take to protect it. The goal of an attack can be as complex as gaining access to your network and the privileged information it contains, or as simple as preventing customers from accessing your web server.

Because of popular media, many people are aware of viruses and other malware as a threat against their computers and data, but some of the most costly malicious attack in history have been against networks. A 2016 study found that a single DDoS attack could cost a company over \$1.6 million. Depending on the size and type of company the areas of expense can be:

- Changes in credit and insurance ratings
- Overtime payment to employees
- Hiring new employees to increase IT staff
- PR expenses to restore a company's reputation
- Upgrading infrastructure and software
- Customer compensation

The following topics are included in this section:

- [Monitoring](#)
- [Blocking external probes](#)
- [Defending against DoS attacks](#)

### Monitoring

Monitoring, in the form of logging, alert email, and SNMP, does not directly protect your network. But monitoring allows you to review the progress of an attack, whether afterwards or while in progress. How the attack unfolds may reveal weaknesses in your preparations. The packet archive and sniffer policy logs can reveal more details about the attack. Depending on the detail in your logs, you may be able to determine the attacker's location and identity.

While log information is valuable, you must balance the log information with the resources required to collect and store it.

### Blocking external probes

Protection against attacks is important, but attackers often use vulnerabilities and network tools to gather information about your network to plan an attack. It is often easier to prevent an attacker from learning important details about your network than to defend against an attack designed to exploit your particular network.

Attacks are often tailored to the hardware or operating system of the target, so reconnaissance is often the first step. The IP addresses of the hosts, the open ports, and the operating systems the hosts are running is invaluable information to an attacker. Probing your network can be as simple as an attacker performing an address sweep or port scan to a more involved operation like sending TCP packets with invalid combinations of flags to see how your firewall reacts.

## Address sweeps

An address sweep is a basic network scanning technique to determine which addresses in an address range have active hosts. A typical address sweep involves sending an ICMP ECHO request (a ping) to each address in an address range to attempt to get a response. A response signifies that there is a host at this address that responded to the ping. It then becomes a target for more detailed and potentially invasive attacks.

Address sweeps do not always reveal all the hosts in an address range because some systems may be configured to ignore ECHO requests and not respond, and some firewalls and gateways may be configured to prevent ECHO requests from being transmitted to the destination network. Despite this shortcoming, Address sweeps are still used because they are simple to perform with software tools that automate the process.

Use the `icmp_sweep` anomaly in a DoS policy to protect against address sweeps.

There are a number of IPS signatures to detect the use of ICMP probes that can gather information about your network. These signatures include `AddressMask`, `Traceroute`, `ICMP.Invalid.Packet.Size`, and `ICMP.Oversized.Packet`. Include ICMP protocol signatures in your IPS sensors to protect against these probes/attacks.

## Port scans

Potential attackers may run a port scan on one or more of your hosts. This involves trying to establish a communication session to each port on a host. If the connection is successful, a service may be available that the attacker can exploit.

Use the DoS anomaly check for `tcp_port_scan` to limit the number of sessions (complete and incomplete) from a single source IP address to the configured threshold. If the number of sessions exceed the threshold, the configured action is taken.

Use the DoS anomaly check for `udp_scan` to limit UDP sessions in the same way.

## Probes using IP traffic options

Every TCP packet has space reserved for eight flags or control bits. They are used for communicating various control messages. Although space in the packet is reserved for all eight, there are various combinations of flags that should never happen in normal network operation. For example, the SYN flag, used to initiate a session, and the FIN flag, used to end a session, should never be set in the same packet.

Attackers may create packets with these invalid combinations to test how a host will react. Various operating systems and hardware react in different ways, giving a potential attackers clues about the components of your network.

The IPS signature `TCP.Bad.Flags` detects these invalid combinations. The default action is pass though you can override the default and set it to **Block** in your IPS sensor.

## Configure packet replay and TCP sequence checking

The anti-replay CLI command allows you to set the level of checking for packet replay and TCP sequence checking (or TCP Sequence (SEQ) number checking). All TCP packets contain a Sequence Number (SEQ) and an Acknowledgement Number (ACK). The TCP protocol uses these numbers for error free end-to-end communications. TCP sequence checking can also be used to validate individual packets.

FortiGate units use TCP sequence checking to make sure that a packet is part of a TCP session. By default, if a packet is received with sequence numbers that fall out of the expected range, the FortiGate unit drops the packet. This is normally a desired behavior, since it means that the packet is invalid. But in some cases you may

want to configure different levels of anti-replay checking if some of your network equipment uses non-RFC methods when sending packets.

Configure the anti-replay CLI command:

```
config system global
    set anti-replay {disable | loose | strict}
end
```

You can set anti-replay protection to the following settings:

- **disable** — No anti-replay protection.
- **loose** — Perform packet sequence checking and ICMP anti-replay checking with the following criteria:
  - The SYN, FIN, and RST bit can not appear in the same packet.
  - The FortiGate unit does not allow more than one ICMP error packet through before it receives a normal TCP or UDP packet.
  - If the FortiGate unit receives an RST packet, and check-reset-range is set to strict, the FortiGate unit checks to determine if its sequence number in the RST is within the un-ACKed data and drops the packet if the sequence number is incorrect.
- **strict** — Performs all of the loose checking but for each new session also checks to determine if the TCP sequence number in a SYN packet has been calculated correctly and started from the correct value for each new session. Strict anti-replay checking can also help prevent SYN flooding.

If any packet fails a check it is dropped.

### Configure ICMP error message verification

Enable ICMP error message verification to ensure an attacker can not send an invalid ICMP error message.

```
config system global
    check-reset-range {disable | strict}
end
```

- **disable** — the FortiGate unit does not validate ICMP error messages.
- **strict** — enable ICMP error message checking.

If the FortiGate unit receives an ICMP error packet that contains an embedded IP(A,B) | TCP(C,D) header, then if FortiOS can locate the A:C->B:D session it checks to make sure that the sequence number in the TCP header is within the range recorded in the session. If the sequence number is not in range then the ICMP packet is dropped. Strict checking also affects how the anti-replay option checks packets.

### Protocol header checking

Select the level of checking performed on protocol headers.

```
config system global
    check-protocol-header {loose | strict}
end
```

- **loose** — the FortiGate unit performs basic header checking to verify that a packet is part of a session and should be processed. Basic header checking includes verifying that the layer-4 protocol header length, the IP header length, the IP version, the IP checksum, IP options are correct, etc.
- **strict** — the FortiGate unit does the same checking as above plus it verifies that ESP packets have the correct sequence number, SPI, and data length.

If the packet fails header checking it is dropped by the FortiGate unit.

## Evasion techniques

Attackers employ a wide range of tactics to try to disguise their techniques. If an attacker disguises a known attack in such a way that it is not recognized, the attack will evade your security and possibly succeed. FortiGate security recognizes a wide variety of evasion techniques and normalizes data traffic before inspecting it.

### Packet fragmentation

Information sent across local networks and the Internet is encapsulated in packets. There is a maximum allowable size for packets and this maximum size varies depending on network configuration and equipment limitations. If a packet arrives at a switch or gateway and it is too large, the data it carries is divided among two or more smaller packets before being forwarded. This is called fragmentation.

When fragmented packets arrive at their destination, they are reassembled and read. If the fragments do not arrive together, they must be held until all of the fragments arrive. Reassembly of a packet requires all of the fragments.

The FortiGate unit automatically reassembles fragmented packets before processing them because fragmented packets can evade security measures. This reassembly of packets affects TCP, UDP and IP packets. There can be some variation though in what process does the reassembling. The IPS engine, nTurbo and the kernel all can do defragmentation.

For example, you have configured the FortiGate unit to block access to the example.org web site. Any checks for example.com will fail if a fragmented packet arrives and one fragment contains `http://www.exa` while the other contains `mple.com/`. Viruses and malware can be fragmented and avoid detection in the same way. The FortiGate unit will reassemble fragmented packets before examining network data to ensure that inadvertent or deliberate packet fragmentation does not hide threats in network traffic.

### Non-standard ports

Most traffic is sent on a standard port based on the traffic type. The FortiGate unit recognizes most traffic by packet content rather than the TCP/UDP port and uses the proper IPS signatures to examine it. Protocols recognized regardless of port include DHCP, DNP3, FTP, HTTP, IMAP, MS RPC, NNTP, POP3, RSTP, SIP, SMTP, and SSL, as well as the supported IM/P2P application protocols.

In this way, the FortiGate unit will recognize HTTP traffic being sent on port 25 as HTTP rather than SMTP, for example. Because the protocol is correctly identified, the FortiGate unit will examine the traffic for any enabled HTTP signatures.

### Negotiation codes

Telnet and FTP servers and clients support the use of negotiation information to allow the server to report what features it supports. This information has been used to exploit vulnerable servers. To avoid this problem, the FortiGate unit removes negotiation codes before IPS inspection.

### HTTP URL obfuscation

Attackers encode HTML links using various formats to evade detection and bypass security measures. For example, the URL `www.example.com/cgi.bin` could be encoded in a number of ways to avoid detection but still work properly, and be interpreted the same, in a web browser.

The FortiGate prevents the obfuscation by converting the URL to ASCII before inspection.

### HTTP URL obfuscation types

Encoding type	Example
<b>No encoding</b>	http://www.example.com/cgi.bin/
<b>Decimal encoding</b>	http://www.example.com/c#103;#105;#46;#98;#105;#110;#47;
<b>URL encoding</b>	http://www.example.com/%43%47%49%2E%42%49%4E%2F
<b>ANSI encoding</b>	http://www.example.com/%u0063%u0067%u0069%u002E%u0062%u0069%u006E/
<b>Directory traversal</b>	http://www.example.com/cgi.bin/test/..

### HTTP header obfuscation

The headers of HTTP requests or responses can be modified to make the discovery of patterns and attacks more difficult. To prevent this, the FortiGate unit will:

- remove junk header lines
- reassemble an HTTP header that's been folded onto multiple lines
- move request parameters to HTTP POST body from the URL

The message is scanned for any enabled HTTP IPS signatures once these problems are corrected.

### HTTP body obfuscation

The body content of HTTP traffic can be hidden in an attempt to circumvent security scanning. HTTP content can be GZipped or deflated to prevent security inspection. The FortiGate unit will uncompress the traffic before inspecting it.

Another way to hide the contents of HTTP traffic is to send the HTTP body in small pieces, splitting signature matches across two separate pieces of the HTTP body. The FortiGate unit reassembles these 'chunked bodies' before inspection.

### Microsoft RPC evasion

Because of its complexity, the Microsoft Remote Procedure Call protocol suite is subject to a number of known evasion techniques, including:

- SMB-level fragmentation
- DCERPC-level fragmentation
- DCERPC multi-part fragmentation
- DCERPC UDP fragmentation
- Multiple DCERPC fragments in one packet

The FortiGate unit reassembles the fragments into their original form before inspection.

## Defending against DoS attacks

A denial of service is the result of an attacker sending an abnormally large amount of network traffic to a target system. Having to deal with the traffic flood slows down or disables the target system so that legitimate users can not use it for the duration of the attack.

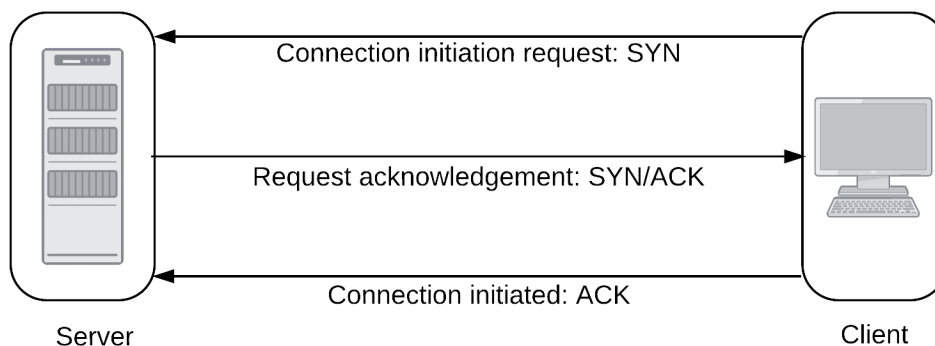

Any network traffic the target system receives has to be examined, and then accepted or rejected. TCP, UDP, and ICMP traffic is most commonly used, but a particular type of TCP traffic is the most effective. TCP packets with the SYN flag are the most efficient DoS attack tool because of how communication sessions are started between systems.

### The “three-way handshake”

Communication sessions between systems start with establishing a TCP/IP connection. This is a simple three step process, sometimes called a “three-way handshake,” initiated by the client attempting to open the connection.

1. The client sends a TCP packet with the SYN flag set. With the SYN packet, the client informs the server of its intention to establish a connection.
2. If the server is able to accept the connection to the client, it sends a packet with the SYN and the ACK flags set. This simultaneously acknowledges the SYN packet the server has received, and informs the client that the server intends to establish a connection.
3. To acknowledge receipt of the packet and establish the connection, the client sends an ACK packet.

### Establishing a TCP/IP connection

The three-way handshake is a simple way for the server and client to each agree to establish a connection and acknowledge the other party expressing its intent. Unfortunately, the three-way handshake can be used to interfere with communication rather than facilitate it.

### SYN flood

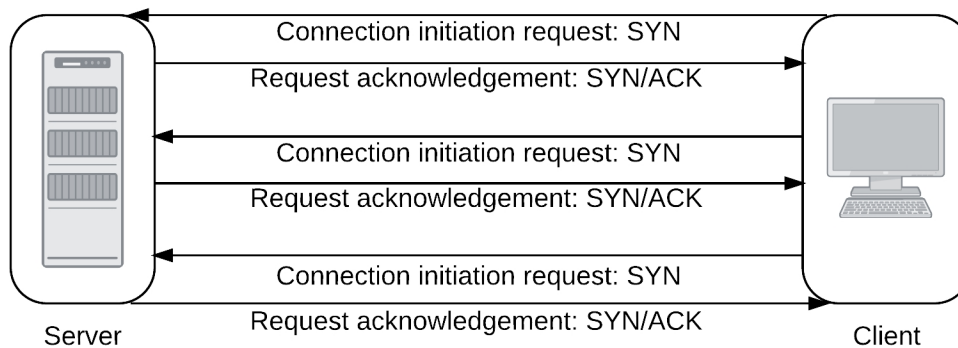

When a client sends a SYN packet to a server, the server creates an entry in its session table to keep track of the connection. The server then sends a SYN+ACK packet expecting an ACK reply and the establishment of a connection.

An attacker intending to disrupt a server with a denial of service (DoS) attack can send a flood of SYN packets and not respond to the SYN+ACK packets the server sends in response. Networks can be slow and packets can get

lost so the server will continue to send SYN+ACK packets until it gives up, and removes the failed session from the session table. If an attacker sends enough SYN packets to the server, the session table will fill completely, and further connection attempts will be denied until the incomplete sessions time out. Until this happens, the server is unavailable to service legitimate connection requests.

### A single client launches a SYN flood attack

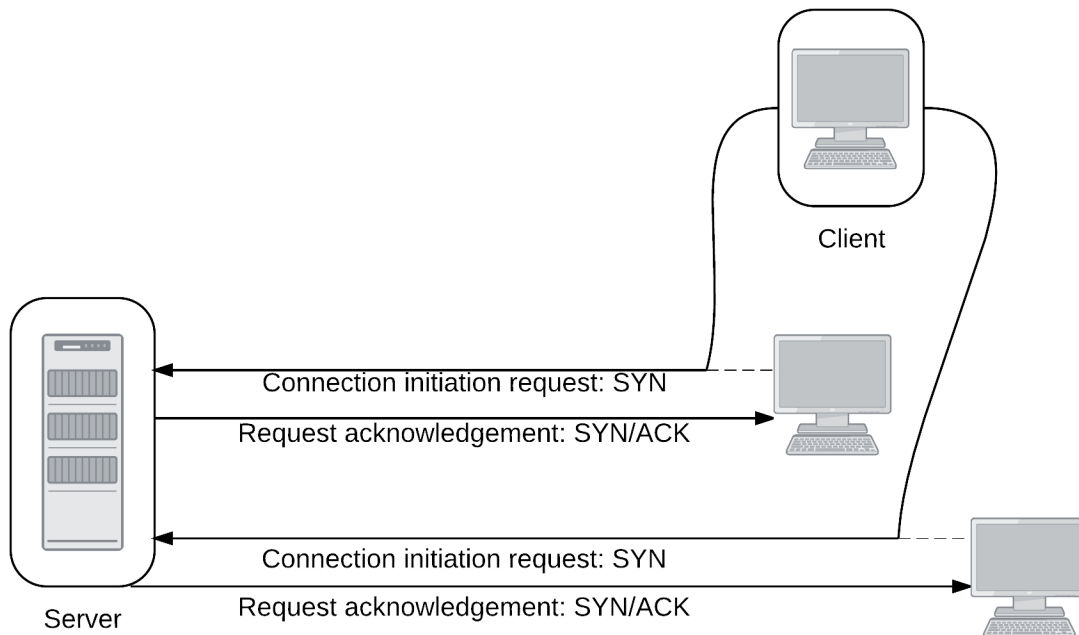

SYN floods are seldom launched from a single address so limiting the number of connection attempts from a single IP address is not usually effective.

### SYN spoofing

With a flood of SYN packets coming from a single attacker, you can limit the number of connection attempts from the source IP address or block the attacker entirely. To prevent this simple defense from working, or to disguise the source of the attack, the attacker may spoof the source address and use a number of IP addresses to give the appearance of a distributed denial of service (DDoS) attack. When the server receives the spoofed SYN packets, the SYN+ACK replies will go to the spoofed source IP addresses which will either be invalid, or the system receiving the reply will not know what to do with it.

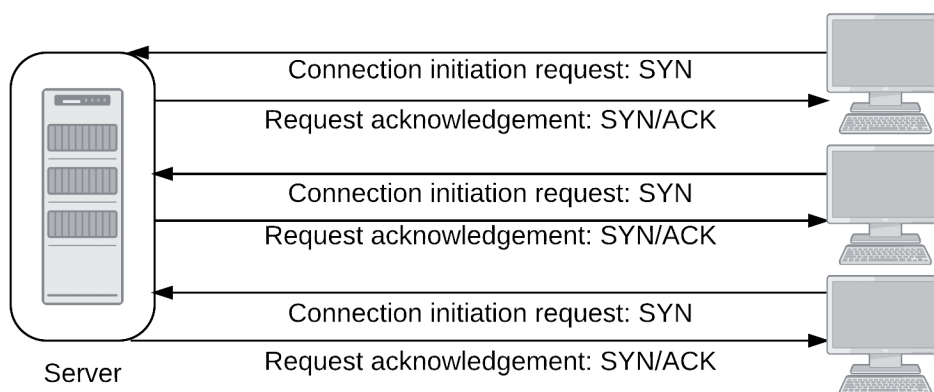

### A client launches a SYN spoof attack

### DDoS SYN flood

The most severe form of SYN attack is the distributed SYN flood, one variety of distributed denial of service attack (DDoS). Like the SYN flood, the target receives a flood of SYN packets and the ACK+SYN replies are never answered. The attack is distributed across multiple sources sending SYN packets in a coordinated attack.

### Multiple attackers launch a distributed SYN flood

The distributed SYN flood is more difficult to defend against because multiple clients are capable of creating a larger volume of SYN packets than a single client. Even if the server can cope, the volume of traffic may

overwhelm a point in the network upstream of the targeted server. The only defense against this is more bandwidth to prevent any choke-points.

## Configuring the SYN threshold to prevent SYN floods

The preferred primary defense against any type of SYN flood is the DoS anomaly check for `tcp_syn_flood` threshold. The threshold value sets an upper limit on the number of new incomplete TCP connections allowed per second. If the number of incomplete connections exceeds the threshold value, and the action is set to **Pass**, the FortiGate unit will allow the SYN packets that exceed the threshold. If the action is set to **Block**, the FortiGate unit will block the SYN packets that exceed the threshold, but it will allow SYN packets from clients that send another SYN packet.

The tools attackers use to generate network traffic will not send a second SYN packet when a SYN+ACK response is not received from the server. These tools will not “retry.” Legitimate clients will retry when no response is received, and these retries are allowed even if they exceed the threshold with the action set to **Block**.

## SYN proxy

FortiGate units with network acceleration hardware, whether built-in or installed in the form of an add-on module, offer a third action for the `tcp_syn_flood` threshold. Instead of **Block** and **Pass**, you can choose to **Proxy** the incomplete connections that exceed the threshold value.

When the `tcp_syn_flood` threshold action is set to **f**, incomplete TCP connections are allowed as normal as long as the configured threshold is not exceeded. If the threshold is exceeded, the FortiGate unit will intercept incoming SYN packets from clients and respond with a SYN+ACK packet. If the FortiGate unit receives an ACK response as expected, it will “replay” this exchange to the server to establish a communication session between the client and the server, and allow the communication to proceed.

## Other flood types

UDP and ICMP packets can also be used for DoS attacks, though they are less common. TCP SYN packets are so effective because the target receives them and maintains a session table entry for each until they time out. Attacks using UDP or ICMP packets do not require the same level of attention from a target, rendering them less effective. The target will usually drop the offending packets immediately, closing the session.

Use the `udp_flood` and `icmp_flood` thresholds to defend against these DoS attacks.

## DoS policies

DDoS attacks vary in nature and intensity. Attacks aimed at saturating the available bandwidth upstream of your service can only be countered by adding more bandwidth. DoS policies can help protect against DDoS attacks that aim to overwhelm your server resources.

## DoS policy recommendations

- Use and configure DoS policies to appropriate levels based on your network traffic and topology. This will help drop traffic if an abnormal amount is received.
- It is important to set a good threshold. The threshold defines the maximum number of sessions/packets per second of normal traffic. If the threshold is exceeded, the action is triggered. Threshold defaults are general recommendations, although your network may require very different values.
- One way to find the correct values for your environment is to set the action to **Pass** and enable logging. Observe the logs and adjust the threshold values until you can determine the value at which normal traffic begins to generate attack reports. Set the threshold above this value with the margin you want. Note that the smaller the margin, the

more protected your system will be from DoS attacks, but your system will also be more likely to generate false alarms.

## Inside FortiOS: Denial of Service (DoS) Protection

FortiOS DoS protection maintains network integrity and performance by identifying and blocking harmful IPv4 and IPv6-based denial of service (DoS) attacks.

### About DoS and DDoS attacks

A denial of service (DoS) occurs when an attacker overwhelms server resources by flooding a target system with anomalous data packets, rendering it unable to service genuine users. A distributed denial of service (DDoS) occurs when an attacker uses a master computer to control a network of compromised systems, otherwise known as a 'botnet', which collectively inundates the target system with excessive anomalous data packets.

### FortiOS DoS and DDoS protection

FortiOS DoS protection identifies potentially harmful traffic that could be part of a DoS or a DDoS attack by looking for specific traffic anomalies. Traffic anomalies that become DoS attacks include: TCP SYN floods, UDP floods, ICMP floods, TCP port scans, TCP session attacks, UDP session attacks, ICMP session attacks, and ICMP sweep attacks. Only traffic identified as part of a DoS attack is blocked; connections from legitimate users are processed normally.

FortiOS applies DoS protection very early in its traffic processing sequence to minimize the effect of a DoS attack on FortiOS system performance. DoS protection is the first step for packets after they are received by a FortiGate interface. Potential DoS attacks are detected and blocked before the packets are sent to other FortiOS systems.

FortiOS also includes an access control list feature that is implemented next. This accelerated ACL technology uses NP6 processors to block traffic (including DoS attacks) by source and destination address and service again before the packets are sent to the FortiGate CPU.

FortiOS DoS protection can operate in a standard configuration or operate out of band in sniffer mode, also known as one-arm mode, similar to intrusion detection systems. When operating in sniffer mode the FortiGate unit detects attacks and logs them without blocking them.

FortiOS DoS policies determine the course of action to take when anomalous traffic reaches a configured packet rate threshold. You can block an attacker, block an interface, block an attacker and interface, or allow traffic to pass through for monitoring purposes. This allows you to maintain network security by gathering information about attacks, monitor potentially offending traffic, or block offenders for the most protection.

FortiGates with NP6 processors also support synproxy DoS protection. An NP6-accelerated TCP SYN proxy offloads the three-way TCP handshake TCP SYN anomaly checking DoS protection to NP6 processors.

## FortiOS DDoS Prevention

In addition to using DoS protection for protection against DoS attacks, FortiOS includes a number of features that prevent the spread of Botnet and C&C activity. Mobile Malware or Botnet and C&C protection keeps Botnet and C&C code from entering a protected network and compromising protected systems. As a result, systems on the protected network cannot become Botnet clients.

In addition, FortiOS can monitor and block outgoing Botnet connection attempts. Monitoring allows you to find and remove Botnet clients from your network and blocking prevents infected systems from communicating with Botnet sites.

## Configuration options

Choose the standard configuration for maximum protection or configure sniffer mode to gather information.

### Standard configuration

DoS protection is commonly configured on a FortiGate unit that connects a private or DMZ network to the Internet or on a FortiWiFi unit that connects a wireless LAN to an internal network and to the Internet. All Internet traffic or wireless LAN traffic passes through DoS protection in the FortiGate unit or the FortiWiFi unit.

### Out of band configuration (sniffer mode)

A FortiGate unit in sniffer mode operates out of band as a one-armed Intrusion Detection System by detecting and reporting attacks. It does not process network traffic nor does it take action against threats. The FortiGate interface operating in sniffer mode is connected to a Test Access Point (TAP) or a Switch Port Analyzer (SPAN) port that processes all of the traffic to be analyzed. The TAP or SPAN sends a copy of the switch traffic to the out of band FortiGate for analysis.

FortiOS records log messages and sends alerts to system administrators when a DoS attack is detected. IDS scanning does not affect network performance or network traffic if the IDS fails or goes offline.

## DoS policies

DoS policies provide effective and early DoS detection while remaining light on system resources. They are configured to monitor and to stop traffic with abnormal patterns or attributes. The DoS policy recognizes traffic as a threat when the traffic reaches a user-configured packet rate threshold. The policy then determines the appropriate action. In addition to choosing whether or not to log each type of anomaly, you can choose to pass or block threats.

DoS policy anomaly protection is applied to all incoming traffic to a single FortiGate interface, but you can narrow policies by specifying service, source address, and destination address. The FortiGate unit processes DoS policies in their own respective order first, followed by all other firewall policies.

## Hardware acceleration

Hardware acceleration enhances protection and increases the efficiency of your network. FortiOS integrated Content Processors (CPs), Network Processors (NPs), and Security Processors (SPs) accelerate specialized security processing. DoS SYN proxy protection is built in to NP6 processors and many Fortinet Security Processors, like the CE4, XE2, and FE8, to guard against TCP SYN floods. TCP packets with the SYN flag are the most efficient DoS attack tool because of how communication sessions are initiated between systems. NP6 and SP processors can offload TCP SYN flood attack detection and blocking. The SP module increases a FortiGate unit's capacity to protect against TCP SYN flood attacks while minimizing the effect of attacks on the FortiGate unit's overall performance and the network performance. The result is improved capacity and overall system performance.

## The FortiGuard Center

The FortiGuard Center shows information on all the most recent FortiGuard news, including information concerning zero-day research and hot intrusion detections. Research papers are also available that concern a variety of current security issues.

To view recent developments, go to <http://www.fortiguard.com/static/intrusionprevention.html>.

## Firewall Policies

The firewall policies of the FortiGate are one of the most important aspects of the appliance. There are a lot of building blocks and configurations involved in setting up a firewall and it within the policies that a lot of these components come together to form a cohesive unit to perform the firewall's main function, analyzing network traffic and responding appropriately to the results of that analysis.

There are a few different kinds of policies and in most cases these are further divided into IPv4 and IPv6 versions:

- [IPv4 Policy](#) - used for managing traffic going through the appliance using IPv4 protocols
- [IPv6 Policy](#) - used for managing traffic going through the appliance using IPv6 protocols
- [NAT64 Policy](#) - used for managing traffic going through the appliance that converts from IPv6 on the incoming interface to IPv4 on the outgoing interface
- [NAT46 Policy](#) - used for managing traffic going through the appliance that converts from IPv4 on the incoming interface to IPv6 on the outgoing interface
- [Multicast Policy](#) - used to manage traffic sent to multiple destinations
- [IPv4 Access Control List](#) - used to filter out packets based on specific IPV4 parameters.
- [IPv6 Access Control List](#) - used to filter out packets based on specific IPV6 parameters.
- [IPv4 DoS Policy](#) - used to prevent malicious or flawed packets on an IPv4 interface from denying access to users.
- [IPv6 DoS Policy](#) - used to prevent malicious or flawed packets on an IPv6 interface from denying access to users.

Because the policy determines whether or not NAT will be used, it is also import to look at how to configure:

- [Central SNAT](#) - used for granular controlling when NATing is in use.

## Viewing Firewall Policies

To find a Policy window, follow one of these path in the GUI:

- **Policy & Objects> IPv4 Policy**
- **Policy & Objects> IPv6 Policy**
- **Policy & Objects> NAT64 Policy**
- **Policy & Objects> NAT46 Policy**
- **Policy & Objects> Proxy Policy**
- **Policy & Objects> Multicast Policy**

You may notice other policy options on the left window pane such as:

- **Policy & Objects> IPv4 DoS Policy**
- **Policy & Objects> IPv6 DoS Policy**
- **Policy & Objects> Local InPolicy**

These are different enough that they have their own descriptions in the sections that relate to them.

## Menu Items

There are some variations, but there are some common elements share by all of them. There is a menu bar across the top. The menu bar will have the following items going from left to right:

- **Create New** button
- **Edit** button
- **Delete** button
- **Search** field
- **Interface Pair View**- Displays the policies in the order that they are checked for matching traffic, grouped by the pairs of Incoming and Outgoing interfaces. For instance, all of the policies referencing traffic from WAN1 to DMZ will be in one section. The policies referencing traffic from DMZ to WAN1 will be in another section. The sections are collapsible so that you only need to look at the sections with policies you are interested in.
- **By Sequence**- Displays the policies in the order that they are checked for matching traffic without any grouping.

### Menu items not shared by all policies

- **Policy Lookup** - (IPv4, IPv6 )
- **NAT64 Forwarding** - (NAT64)

## The Table of Policies

### Columns

The tables that make up the Policy window are based on rows which represent individual policies and the columns that represent the various parameters or status within the policy. The columns are customizable by which columns are included and what order they are in.

The table can be laid out a number ways to suit the viewer. There is a column for most of the important pieces of information that you might be interested in seeing, but a lot of them are hidden by default. If you had a large enough screen, you might be able to show all of the columns, but even then it might look a bit busy and cramped together. Figure out which pieces of information are most important to you and hide the rest.

To configure which columns are visible and which are hidden, right click on the header row of the table. This will present a drop down menu. The drop down will be divided into sections. At the top will be the **Selected Columns** which are currently visible, and the next section will be **Available Columns** which show which columns are available to add to the table.

To move a column from the **Available** list to the **Selected** list just click on it. To move a column from the **Selected** list to the **Available** list, it also just takes a click of the mouse. To make the changes show up on the table, go to the bottom of the drop down menu and select **Apply**. Any additions to the table will show up on the right side.

One of the more useful ones that can be added is the ID column. The reason for adding this one is that within the configuration file and CLI, the policies are referenced by their ID number. Some policy settings are only available for configuration in the CLI. If you are looking in the CLI you will see that the only designation for a policy is its number and if you wish to edit the policy or change its order in the sequence you will be asked to move it before or after another policy by referencing its number.

### How “Any” policy can remove the Interface Pair View

The FortiGate unit will automatically change the view on the policy list page to **By Sequence** whenever there is a policy containing “any” as the Source or Destination interface. If the **Interface Pair View** is grayed out it is likely that one or more of the policies has used the “any” interface.

By using the “any” interface, the policy should go into multiple sections because it could effectively be any of a number of interface pairings. As mentioned, policies are sectioned by using the interface pairings (for example,

port1 -> port2) and each section has its own specific policy order. The order in which a policy is checked for matching criteria to a packet's information is based solely on the position of the policy within its section or within the entire list of policies as a whole but if the policy is in multiple sections at the same time there is no mechanism for placing the policy in a proper order within all of those sections at the same time because it is a manual process and there is no parameter to compare the precedence of one section or policy over the other. Thus a conflict is created. In order to resolve the conflict the FortiGate firewall removes that aspect of the sections so that there is no need to compare and find precedence between the sections and it therefore has only the Global View to work with.

## Policy Names

Each policy has a name field. Every policy name must be unique for the current VDOM regardless of policy type. Previous to FortiOS 5.4, this field was optional.

On upgrading from an earlier version of FortiOS to 5.4, policy names are not assigned to old policies, but when configuring new policies, a unique name must be assigned to the policy.

---

### Configuring the Name field

#### GUI

In the GUI, the field for the policy name is the first field on the editing page.

#### CLI

In the CLI, the syntax for assigning the policy name is:

```
config firewall [policy|policy6]
  edit 0
    set name <policy name>
  end
```

### Disabling Policy name requirement

While by default the requirement of having a unique name for each policy is the default, it can be enabled or disabled. Oddly enough, if disabling the requirement is a one time thing, doing it in the CLI is more straightforward.

This setting is VDOM based so if you are running multiple VDOMs, you will have to enter the correct VDOM before entering the CLI commands or turning the feature on or off in the GUI.

---

#### GUI

To edit the requirement in the GUI, the ability to do so must be enabled in the CLI. The syntax is:

```
config system settings
  set gui-allow-unnamed-policy [enable|disable]
end
```

Once it has been enabled, the requirement for named policies can be relaxed by going to **System > Feature Visibility**. Allow **Unnamed Policies** can be found under **Additional Features**. Here you can toggle the requirement on and off.

## CLI

To change the requirement in the CLI, use the following syntax:

```
config system settings
    set gui-advance policy [enable|disable]
end
```

## IPv4 Policy

### To configure a IPv4 policy in the GUI

#### 1. Go to **Policy & Objects > IPv4 Policy**

The right side window will display a table of the existing IPv4 Policies.

- To edit an existing policy, double click on the policy you wish to edit
- To create a new policy, select the **Create New** icon in the top left side of the right window.

#### 2. Make sure the policy has a name in the **Name** field

By default, a policy is required to have a name, but it is possible to toggle this requirement on or off in the CLI, or in the GUI if you have first enabled the GUI option in the CLI.

- #### 3. Set the **Incoming Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces or you can select the **any** option. Choosing the any option will remove any other interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
- #### 4. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)

Alias names for interfaces, if used, appear in the headings for the Interface Pair View or what used to be called the Section View.

Multiple interfaces or ANY interface can be added to a firewall policy. This feature can be enabled or disabled in the GUI by going to the **System > Feature Select** page and toggling **Multiple Interface Policies**.

When selecting the Incoming or Outgoing interface of a policy, there are a few choices:

- The **ANY** interface (choosing this will remove all other interfaces)
- 1 A single specific interface
- 1 multiple specific interfaces (can be added at the same time or one at a time)

The GUI is intuitive and straightforward on how to do this. Click on the "+" symbol in the interface field and then select the desired interfaces from the side menu. There are a couple of ways to do it in the CLI:

1. Set the interfaces all at once:

```
config firewall policy
edit 0
set srcintf wan1 wan2
end
```

2. Set the first interface and append additional ones:

```
config firewall policy
edit 0
set srcintf wan1
append srcintf wan2
end
```

5. Set the **Source** parameter by selecting the field with the "+" next to the field label. The source in this case is either the source address, source user or source device of the initiating traffic. When the field is selected a window will slide out from the right. Tabs indicating **Address**, **User** or **Device** options are there to help categorize the options along with the option to search. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. For the **Address** and **Device** tabs, single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
6. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field but address objects are the only available options to select. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
7. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
8. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
9. Set the **Action** parameter. Select one of the following options for the action:
  - **ACCEPT** - lets the traffic through to the next phase of analysis
  - **DENY** - drops the session

- **LEARN** - collects information about the traffic for future analysis
- **IPsec** - for using with IPsec tunnels

Because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

### Settings if the **ACCEPT** action is selected.

#### Firewall / Network Options

10. Set the **NAT** parameter by toggling the slider button. (gray means it is disabled)

The NAT setting section is affected by whether or not Central NAT is enabled.

If Central NAT is enabled, the only option in Firewall / Network options will be whether to enable or disable NAT. The rest of the NAT parameters will be set in the Central SNAT page.

If Central NAT is disabled, there are two additional settings in the Policy configuration page.

11. Set the **Fixed Port** parameter by toggling the slider button. (gray means it is disabled)
12. Set the **IP Pool Configuration** by selection one of the options of:
  - **Use Outgoing Interface Address**
  - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected, an additional field will appear with the **+** icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the **+** icon next to the **Search** field is a shortcut for creating a new IP Pool.

#### Security Profiles

13. Enabling the **Use Security Profile Group** option will allow the selection of a profile group instead of selecting the individual profiles for the policy.
14. Disable or enable the various **Security Profiles**. Once a Profile has been toggled into the enabled mode a drop down menu will appear for the purpose of choosing a specific profile. Only one profile can be chosen for each profile type. The **+** icon next to the **Search** field in the drop down menu is a shortcut for creating a new profile.

The list of **Security Profiles** available to set includes:

- **AntiVirus**
- **Web Filter**
- **DNS Filter**
- **Application Control**
- **CASI**
- **IPS**
- **Anti-Spam**
- **DLP Sensor**
- **VoIP**
- **ICAP**
- **Web Application Firewall**
- **Proxy Options**
- **SSL/SSH Inspection**

#### Logging Options

15. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).

If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.

16. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
17. Toggle whether or not to **Enable this policy**. The default is enabled.
18. Select the **OK** button to save the policy.

#### Settings if the DENY action is selected

**Enable the Log Violation Traffic setting by toggling the slider button.**

10. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

#### Settings if the LEARN action is selected

To get more information on the **LEARN** option, read the Learning mode for Firewall policies topic in [What's new for Firewall in 5.6](#)

#### Firewall / Network Options

10. Set the **NAT** parameter by toggling the slider button. (gray means it is disabled). Unlike the **ACCEPT** option, whether or not Central NAT is enabled or disabled does not affect this settings options.
11. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
12. Toggle whether or not to **Enable this policy**. The default is enabled.
13. Select the **OK** button to save the policy.

#### Settings if the IPsec action is selected

##### VPN Tunnel

10. For the VPN Tunnel field, use the drop down menu to select the VPN tunnel that you want the policy associated with.
  11. Toggle the sliding button to enable or disable the option to **Allow traffic to be initiated from the remote site**
- #### Security Profiles

12. Disable or enable the various **Security Profiles**. Once a Profile has been toggled into the enabled mode a drop down menu will appear for the purpose of choosing a specific profile. Only one profile can be chosen for each profile type. The "+" icon next to the **Search** field in the drop down menu is a shortcut for creating a new profile.

The list of **Security Profiles** available to set includes:

- **AntiVirus**
- **Web Filter**
- **DNS Filter**
- **Application Control**
- **CASI**
- **IPS**
- **Anti-Spam**
- **DLP Sensor**

- VoIP
- ICAP
- Web Application Firewall
- Proxy Options
- SSL/SSH Inspection

### Logging Options

13. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).

If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.

14. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
15. Toggle whether or not to **Enable this policy**. The default is enabled.
16. Select the **OK** button to save the policy.

## IPv6 Policy

### To configure a IPv6 policy in the GUI

1. Go to **Policy & Objects > IPv6 Policy**

The right side window will display a table of the existing IPv6 Policies.

- To edit an existing policy, double click on the policy you wish to edit
- To create a new policy, select the **Create New** icon in the top left side of the right window.

2. Make sure the policy has a name in the **Name** field

By default, a policy is required to have a name, but it is possible to toggle this requirement on or off in the CLI, or in the GUI if you have first enabled the GUI option in the CLI.

3. Set the **Incoming Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces or you can select the **any** option. Choosing the any option will remove any other interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
4. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)
5. Set the **Source** parameter by selecting the field with the "+" next to the field label. The source in this case is either the source address, source user or source device of the initiating traffic. When the field is selected a window will slide out from the right. Tabs indicating **Address**, **User** or **Device** options are there to help categorize the options along with the option to search. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. For the **Address** and **Device** tabs, single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.

6. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field but address objects are the only available options to select. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
7. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
8. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
9. Set the **Action** parameter. Select one of the following options for the action:
  - **ACCEPT** - lets the traffic through to the next phase of analysis
  - **DENY** - drops the session

While there are not as many Action options as with the IPv4 policy, because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

#### Settings if the **ACCEPT** action is selected.

##### Firewall / Network Options

10. Set the NAT parameter by toggling the slider button. (gray means it is disabled)
11. Set the **IP Pool Configuration** by selection one of the options of:
  - **Use Outgoing Interface Address**
  - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected:

- An additional field will appear with the + icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the "+" icon next to the **Search** field is a shortcut for creating a new IP Pool.
- An additional option to **Preserve the Source Port** will appear as a toggle option. If the slider button is grayed out it is disabled.

##### Security Profiles

12. Enabling the **Use Security Profile Group** option will allow the selection of a profile group instead of selecting the individual profiles for the policy.
13. Disable or enable the various **Security Profiles**. Once a Profile has been toggled into the enabled mode a drop down menu will appear for the purpose of choosing a specific profile. Only one profile can be chosen for each profile type. The "+" icon next to the **Search** field in the drop down menu is a shortcut for creating a new profile.

The list of **Security Profiles** available to set includes:

- **AntiVirus**
- **Web Filter**
- **Application Control**
- **IPS**
- **Anti-Spam**
- **DLP Sensor**

- VoIP
- ICAP

### Logging Options

14. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).  
If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.
15. Add a comment to give a detailed description of the policy in the **Comments** field (up to 1023 characters).
16. Toggle whether or not to **Enable this policy**. The default is enabled.
17. Select the **OK** button to save the policy.

### Settings if the DENY action is selected

Enable the **Log Violation Traffic** setting by toggling the slider button.

10. Add a comment to give a detailed description of the policy in the **Comments** field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

## NAT64 Policy

### To configure a NAT64 policy in the GUI

1. Go to **Policy & Objects > NAT64 Policy**

The right side window will display a table of the existing NAT64 Policies.

- To edit an existing policy, double click on the policy you wish to edit
  - To create a new policy, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces or you can select the **any** option. Choosing the any option will remove any other interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
  3. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)
  4. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. The source in this case is an IPv6 Address object of the initiating traffic. When the field is selected a window will slide out from the right. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
  5. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source Address** field. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
  6. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)

7. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
8. Set the **Action** parameter. Select one of the following options for the action:
  - **ACCEPT** - lets the traffic through to the next phase of analysis
  - **DENY** - drops the session

While there are not as many Action options as with the IPv4 policy, because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

#### Settings if the **ACCEPT** action is selected.

##### Firewall / Network Options

10. Skip the NAT setting. This type of policy is intended only for traffic that is being NATed from IPv6 to IPv4, because without NATing the traffic couldn't reach its destination, so disabling NAT would be pointless.
11. Set the **IP Pool Configuration** by selection one of the options of:
  - **Use Outgoing Interface Address**
  - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected, an additional field will appear with the + icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the "+" icon next to the **Search** field is a shortcut for creating a new IP Pool.

12. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).

If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.
13. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
14. Toggle whether or not to **Enable this policy**. The default is enabled.
15. Select the **OK** button to save the policy.

#### Settings if the **DENY** action is selected

Enable the Log Violation Traffic setting by toggling the slider button.

10. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

## NAT46 Policy

### To configure a NAT46 policy in the GUI

1. Go to **Policy & Objects > NAT46 Policy**

The right side window will display a table of the existing NAT46 Policies.

- To edit an existing policy, double click on the policy you wish to edit
  - To create a new policy, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by selecting the field with the "+" next to the field label. Selecting the field will slide out a window from the right where you can select from the available interfaces. You can select one or more specific interfaces or you can select the **any** option. Choosing the any option will remove any other interfaces. For more information on interfaces, check the Concepts section called [Interfaces and Zones](#).
  3. Set the **Outgoing Interface** parameter by selecting the field with the "+" next to the field label. (Same rules apply as with the above step.)
  4. Set the **Source** parameter by selecting the field with the "+" next to the field label. The source in this case is either the source address, source user or source device of the initiating traffic. When the field is selected a window will slide out from the right. Tabs indicating **Address**, **User** or **Device** options are there to help categorize the options along with the option to search. In order to be able to select one of these options it needs to be configured as a firewall object before hand. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object based on the tab that is currently selected. For the **Address** and **Device** tabs, single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
  5. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field but address objects are the only available options to select. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
  6. Set the **Schedule** parameter by using the drop down menu to select a preconfigured schedule. The "+" icon next to the **Search** field is a shortcut for creating a new schedule object. For more information on addresses, check the Firewall Objects section called [Firewall schedules](#)
  7. Set the **Service** parameter by selecting the field with the "+" next to the field label. (Same mechanics for selection apply as with the other similar fields in this window.) Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
  8. Set the **Action** parameter. Select one of the following options for the action:
    - **ACCEPT** - lets the traffic through to the next phase of analysis
    - **DENY** - drops the session

While there are not as many Action options as with the IPv4 policy, because the choice of **Action** determines the settings and options below this parameter in the window the rest of the step are associated with a specific **Action**.

### Settings if the **ACCEPT** action is selected.

#### Firewall / Network Options

10. Skip the NAT setting. This type of policy is intended only for traffic that is being NATed from IPv4 to IPv6, because without NATing the traffic couldn't reach its destination, so disabling NAT would be pointless.
11. Set the **Fixed Port** parameter by toggling the slider button. (gray means it is disabled)
12. Set the **IP Pool Configuration** by selection one of the options of:
  - **Use Outgoing Interface Address**
  - **Use Dynamic IP Pool**

If the **Use Dynamic IP Pool** option is selected, an additional field will appear with the + icon. Selecting this field will slide out a window from the right where a preexisting IP Pool can be chosen. One or more IP Pools can be chosen and the "+" icon next to the **Search** field is a shortcut for creating a new IP Pool.

14. Set the **Log Allowed Traffic** parameter by toggling the slider button (gray means it is disabled).

If the **Log Allowed Traffic** setting is enabled, choose whether to log just **Security Events** or **All Sessions** and determine whether or not to keep a record of the packets by toggling the **Capture Packets** setting on or off.

15. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
16. Toggle whether or not to **Enable this policy**. The default is enabled.
17. Select the **OK** button to save the policy.

### Settings if the DENY action is selected

**Enable the Log Violation Traffic setting by toggling the slider button.**

10. Add a comment to give a detailed description of the policy in the Comments field (up to 1023 characters).
11. Toggle whether or not to **Enable this policy**. The default is enabled.
12. Select the **OK** button to save the policy.

## Central SNAT

The Central NAT feature is not enabled by default. When `central-nat` is enabled, `nat` option under IPv4 policies is skipped and SNAT must be done via `central-snat-map`.

- Info messages and redirection links have been added to IPv4 policy list and dialog to indicate the above
- If NGFW mode is policy-based, then it is assumed that central-nat (specifically SNAT) is enabled implicitly
- The option to toggle NAT in central-snat-map policies has been added (previously it was only shown in NGFW policy-based mode).
- In central-snat policy dialog, the port-mapping fields for the original port have been updated to accept ranges.
- Nat will be skipped in firewall policy if per vdom central nat is enabled.
- The Central SNAT window contains a table of all of the Central SNAT policies.

To toggle the feature on or off, use the following commands:

```
config system settings
    set central-nat [enable | disable]
end
```

When Central NAT is enabled the **Central SNAT** section will appear under the Policy & Objects heading in the GUI.

### To configure a Central SNAT entry in the GUI

#### 1. Goto **Policy & Objects > Central SNAT**

The right side window will display a table of the existing Central SNAT entries.

- To edit an existing entry, double click on the policy you wish to edit
  - To create a new entry, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface(s)** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available interfaces. Selecting a listed interface will highlight it in the window and add it to the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed.
  3. Set the **Outgoing Interface(s)** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available interfaces. Selecting a listed interface will highlight it in the window and add it to

the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed.

4. Set the **Source Address** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available address objects. Selecting a listed object will highlight it in the window and add it to the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed. For more information on addresses, check the Firewall Objects section called [Addresses](#).
5. Set the **Destination Address** by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available address objects. Selecting a listed object will highlight it in the window and add it to the field. Clicking on an object in this window while it's highlighted will remove it from the field. Multiple selections are allowed.

### Under the NAT Heading

6. Set the **IP Pool Configuration** parameter by selecting either **Use Outgoing Interface Address** or **Use Dynamic IP Pool**.
  - If Use Dynamic IP Pool is chosen, a field will appear just beneath the option that is used to select which IP Pool object will be used. Set the IP Pool by clicking on the "+" in the field. This will slide out a window from the right. Here, you can select from the available objects.

7. Set the **Protocol** parameter.

There are 5 options for the **Protocol**.

- **ANY** - any protocol traffic
- **TCP** - TCP traffic only. Protocol number set to 6
- **UDP** - UDP traffic only. Protocol number set to 17
- **SCTP** - SCTP traffic only. Protocol number set to 132
- **Specify** - User can specify the traffic filter protocol by setting the protocol number in the field.

6. If the IP Pool is of the type: Overload, **Explicit Port Mapping** can be enabled.

To enable or disable, use the check box. Once enabled, the following additional parameters will appear.

- **Original Source Port** - in the left number field, set the starting number of the source port range.
- **Translated Port** - in the left number field, set the starting number of the translated port range. If it is a single port range leave the right number field alone. If the right number field is set to a number higher than the left, the right number field for the Original Source Port will change to make sure the 2 number ranges have a matching number of ports.

7. Select the **OK** button to save the entry.

### To configure Central SNAT in the CLI

1. Using the CLI interface of your choice, run the following command to get to the correct context.

```
config firewall central-snat-map
```

- To edit an existing entry, run the command `show` or `show full-configuration` to get a listing of all of the entries in the map. Take note of the policy ID for the entry to be edited.
- To create a new entry the next step will use the policy ID 0 which will check for an unused ID number and create an entry with that number.

2. Edit or create an entry with the correct policy ID

```
edit <policyID number>
```

Run the following commands to set the parameters of the entry:

```
set status [enable|disable]
```

```
set orig-addr <valid address object preconfigured on the FortiGate>
set srcintf <name of interface on the FortiGate>
set dst-addr <valid address object preconfigured on the FortiGate>
set dstintf <name of interface on the FortiGate>
set protocol <integer for protocol number>
set orig-port <integer for original port number>
set nat-port <integer for translated port number>
```

3. Save the entry by running the command `end` or `next`.

### Example scenarios to showing how CLI treats central-nat

#### Make nat available regardless of NGFW mode.

```
config firewall central-snat-map
edit 1
set orig-addr "192-86-1-86"
set srcintf "port23"
set dst-addr "192-96-1-96"
set dstintf "port22"
set nat-ippool "pool1"
set protocol 17
set orig-port 2896-2897
set nat enable
end
```

#### Hide nat-port if nat-ippool is not set or NAT is disabled.

```
config firewall central-snat-map
edit 1
set orig-addr "192-86-1-86"
set srcintf "port23"
set dst-addr "192-96-1-96"
set dstintf "port22"
set nat-ippool "pool1"
set protocol 17
set orig-port 2896-2897
set nat disable
end
```

#### Change orig-port to accept range

```
config firewall central-snat-map
edit 1
set orig-addr "192-86-1-86"
set srcintf "port23"
set dst-addr "192-96-1-96"
set dstintf "port22"
set nat-ippool "pool1"
set protocol 17
set orig-port 2896-2897 (help text changed to: Original port or port range).
set nat-port 35804-35805
end
```

## IPv4 Access Control List

The **IPv4 Access Control List** is a specialized policy for denying IPv4 traffic based on:

- the incoming interface
- the source addresses of the traffic
- the destination addresses of the traffic
- the services or ports the traffic is using

The only action available in this policy is **DENY**

For more information on see [Access Control Lists](#)

### To configure a IPv4 Access Control List entry in the GUI

#### 1. Goto **Policy & Objects > IPv4 Access Control List**

The right side window will display a table of the existing IPv4 Access Control List entries.

- To edit an existing entry, double click on the policy you wish to edit
  - To create a new entry, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.
  3. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
  4. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
  5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
  6. Toggle whether or not to **Enable this policy**. The default is enabled.
  7. Select the **OK** button to save the policy.

### To configure a IPv4 Access Control List entry in the CLI

Use the following syntax:

```
config firewall acl
  edit <acl Policy ID #>
    set status enable
    set interface <interface>
    set srcaddr <address object>
    set dstaddr <address object>
    set service <service object>
  end
end
```

## IPv6 Access Control List

The **IPv6 Access Control List** is a specialized policy for denying IPv6 traffic based on:

- the incoming interface
- the source addresses of the traffic

- the destination addresses of the traffic
- the services or ports the traffic is using

The only action available in this policy is **DENY**

## To configure a IPv6 Access Control List entry in the GUI

### 1. Goto **Policy & Objects > IPv6 Access Control List**

The right side window will display a table of the existing IPv6 Access Control List entries.

- To edit an existing entry, double click on the policy you wish to edit
  - To create a new entry, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.
  3. Set the **Source IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
  4. Set the **Destination IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
  5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
  6. Toggle whether or not to **Enable this policy**. The default is enabled.
  7. Select the **OK** button to save the policy.

## To configure a IPv6 Access Control List entry in the CLI

Use the following syntax:

```
config firewall acl6
edit <acl Policy ID #>
set status enable
set interface <interface>
set srcaddr <address object>
set dstaddr <address object>
set service <service object>
end
end
```

## IPv4 DoS Policy

### To configure a IPv4 DoS Policy in the GUI

#### 1. Goto **Policy & Objects > IPv4 DoS Policy**

The right side window will display a table of the existing IPv4 DoS Policies.

- To edit an existing policy, double click on the policy you wish to edit
  - To create a new policy, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.
  3. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).

4. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
6. Set the parameters for the various traffic anomalies.

All of the anomalies that profiles have been created for are in 2 tables. These tables break up the anomaly profiles into **L3 Anomalies** and **L4 Anomalies**. All of the anomalies have the following parameters that can be set on a per anomaly or per column basis.

- Status - enable or disable the indicated profile
- Logging - enable or disable logging of the indicated profile being triggered
- Action - whether to Pass or Block traffic when the threshold is reached
- Threshold - the number of anomalous packets detected before triggering the action.

The listing of anomaly profiles includes:

### L3 Anomalies

- ip\_src\_session
- ip\_dst\_session

### L4 Anomalies

- tcp\_syn\_flood
- tcp\_port\_scan
- tcp\_src\_session
- tcp\_dst\_session
- udp\_flood
- udp\_scan
- udp\_src\_session
- udp\_dst\_session
- icmp\_flood
- icmp\_sweep
- icmp\_src\_session
- sctp\_flood
- sctp\_scan
- sctp\_src\_session
- sctp\_dst\_session

7. Toggle whether or not to **Enable this policy**. The default is enabled.
8. Select the **OK** button to save the policy.

## Example

The company wishes to protect against Denial of Service attack. They have chosen some where they wish to block the attacks of the incidence goes above a certain threshold and for some others they are just trying to get a baseline of activity for those types of attacks so they are letting the traffic pass through without action.

- The interface to the Internet is on WAN1
- There is no requirement to specify which addresses are being protected or protected from.
- The protection is to extend to all services.
- The TCP attacks are to be blocked
- The UDP, ICMP, and IP attacks are to be recorded but not blocked.
- The SCTP attack filters are disabled
- The tcp\_syn\_flood attack's threshold is to be changed from the default to 1000

### Configuring the DoS Policy in the GUI

1. Go to **Policy & Objects > Policy > DoS**.
2. Create a new policy
3. Fill out the fields with the following information:

Field	Value
Incoming Interface	wan1
Source Address	all
Destination Addresses	all
Service	ALL

### L3 Anomalies

Name	Status	Logging	Action	Threshold
ip_src_session	enabled	enabled	Pass	5000
ip_dst_session	enabled	enabled	Pass	5000

### L4 Anomalies

Name	Status	Logging	Action	Threshold
tcp_syn_flood	enabled	enabled	Block	1000
tcp_port_scan	enabled	enabled	Block	<default value>
tcp_src_session	enabled	enabled	Block	<default value>
tcp_dst_session	enabled	enabled	Block	<default value>
udp_flood	enabled	enabled	Pass	<default value>

Name	Status	Logging	Action	Threshold
udp_scan	enabled	enabled	Pass	<default value>
udp_src_session	enabled	enabled	Pass	<default value>
udp_dst_session	enabled	enabled	Pass	<default value>
icmp_flood	enabled	enabled	Pass	<default value>
icmp_sweep	enabled	enabled	Pass	<default value>
icmp_src_session	enabled	enabled	Pass	<default value>
icmp_dst_session	enabled	enabled	Pass	<default value>
sctp_flood	not enabled	not enabled	Pass	<default value>
sctp_scan	not enabled	not enabled	Pass	<default value>
sctp_src_session	not enabled	not enabled	Pass	<default value>
sctp_dst_session	not enabled	not enabled	Pass	<default value>

4. Toggle the button next to **Enable this policy** to **ON**.
5. Select **OK**.

### Configuring the IPv4 DoS Policy in the GUI

Using the CLI of your choice, enter the following commands:

```
config firewall DoS-policy
edit 0
set status enable
set interface wan1
set srcaddr all
set dstaddr all
set service ALL
config anomaly
edit "tcp_syn_flood"
set status enable
set log disable
set action block
set threshold 1000
next
edit "tcp_port_scan"
set status enable
set log disable
set action block
set threshold 1000
next
edit "tcp_src_session"
set status enable
set log disable
```

```
        set action block
        set threshold 5000
    next
edit "tcp_dst_session"
    set status enable
    set log disable
    set action block
    set threshold 5000
    next
edit "udp_flood"
    set status enable
    set log disable
    set action pass
    set threshold 2000
    next
edit "udp_scan"
    set status enable
    set log disable
    set action pass
    set quarantine none
    set threshold 2000
    next
edit "udp_src_session"
    set status enable
    set log disable
    set action pass
    set threshold 5000
    next
edit "udp_dst_session"
    set status enable
    set log disable
    set action pass
    set threshold 5000
    next
edit "icmp_flood"
    set status enable
    set log disable
    set action pass
    set threshold 250
    next
edit "icmp_sweep"
    set status enable
    set log disable
    set action pass
    set threshold 100
    next
edit "icmp_src_session"
    set status enable
    set log disable
    set action pass
    set threshold 300
    next
edit "icmp_dst_session"
    set status enable
    set log disable
    set action pass
    set threshold 1000
```

```

        next
    edit "ip_src_session"
        set status disable
        set log enable
        set action pass
        set threshold 5000
    next
    edit "ip_dst_session"
        set status disable
        set log enable
        set action pass
        set threshold 5000
    next
    edit "sctp_flood"
        set status disable
        set log disable
        set action pass
        set threshold 2000
    next
    edit "sctp_scan"
        set status disable
        set log disable
        set action pass
        set threshold 1000
    next
    edit "sctp_src_session"
        set status disable
        set log disable
        set action pass
        set threshold 5000
    next
    edit "sctp_dst_session"
        set status disable
        set log disable
        set action pass
        set threshold 5000
    next
end
end
end

```

In this example of the CLI, all of the relevant settings have been left in, but some of them are default settings and would not have to have been specifically set to work. For instance, if the action parameter is not set it automatically defaults to pass.

## IPv6 DoS Policy

### To configure a IPv6 DoS Policy in the GUI

#### 1. Go to **Policy & Objects > IPv6 DoS Policy**

The right side window will display a table of the existing IPv6 DoS Policies.

- To edit an existing policy, double click on the policy you wish to edit
  - To create a new policy, select the **Create New** icon in the top left side of the right window.
2. Set the **Incoming Interface** parameter by using the drop down menu to select a single interface.
  3. Set the **Source IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option. For more information on addresses, check the Firewall Objects section called [Addresses](#).
  4. Set the **Destination IPv6 Address** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
  5. Set the **Services** parameter by selecting the field with the "+" next to the field label. Single or multiple options can be selected unless the **ALL** option is chosen in which case, it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).
  6. Set the parameters for the various traffic anomalies.

All of the anomalies that profiles have been created for are in 2 tables. These tables break up the anomaly profiles into **L3 Anomalies** and **L4 Anomalies**. All of the anomalies have the following parameters that can be set on a per anomaly or per column basis.

- Status - enable or disable the indicated profile
- Logging - enable or disable logging of the indicated profile being triggered
- Action - whether to Pass or Block traffic when the threshold is reached
- Threshold - the number of anomalous packets detected before triggering the action.

The listing of anomaly profiles includes:

### L3 Anomalies

- ip\_src\_session
- ip\_dst\_session

### L4 Anomalies

- tcp\_syn\_flood
- tcp\_port\_scan
- tcp\_src\_session
- tcp\_dst\_session
- udp\_flood
- udp\_scan
- udp\_src\_session
- udp\_dst\_session
- icmp\_flood
- icmp\_sweep
- icmp\_src\_session
- icmp\_dst\_session
- sctp\_flood
- sctp\_scan

7. Toggle whether or not to **Enable this policy**. The default is enabled.
8. Select the **OK** button to save the policy.

## Configuring the IPv6 DoS Policy in the GUI

The configuring of the IPv6 version of the DoS policy is the same as in the IPv4 version , with the exception of first command.

Using the CLI of your choice, enter the following commands:

```
config firewall DoS-policy6
```

The rest of the settings are the same as in IPv4 Dos Policy.

## Multicast Policy

The **Multicast Policy** GUI page has been updated from previous versions of the firmware to the new GUI look and feel. Some functionality has also been changed.

The DNAT option has been removed from the GUI but is still in the CLI.

To create/edit a multicast policy go to **Policy & Objects > Multicast Policy**. The Listing window on the right will have buttons along the top that will enable you to

- **Create New**
- **Edit**
- **Delete**

There is also a **Search** field that will allow you to search or filter the available policies if you have a lot of them.

To configure a new policy left click on the **Create New** button. This will reveal the New Policy editing window.

1. Using the drop down menu, fill in the field for **Incoming Interface**. Only one interface can be chosen.
2. Using the drop down menu, fill in the field for **Outgoing Interface**. Only one interface can be chosen.
3. Set the **Source Address** parameter by selecting the field with the "+" next to the field label. When the field is selected a window will slide out from the right. In order for a multicast address to be available for selection, the address object needs to have been created already. Only useable address options will be available for selection. This means only multicast address objects and the more generic **all** and **none** options. The "+" icon next to the **Search** field is a shortcut for creating a new firewall object. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
4. Set the **Destination Address** parameter by selecting the field with the "+" next to the field label. This field is similar to the **Source** field. Single or multiple options can be selected unless the **all** option is chosen in which case, it will be the only option.
5. Set the **Action** parameter. This will be to either **ACCEPT** or **DENY** the traffic through the policy.
6. Toggle the **Enable SNAT** switch to the setting you want. If the slider is gray the option is disabled. If it is colored, it is enabled.
7. Use the drop down menu to select a **Protocol**. The options are:
  - **Any**
  - **ICMP**
  - **IGMP**
  - **TCP** - includes **Port Range** fields
  - **UDP** - includes **Port Range** fields
  - **OSPF**
  - **Other** - includes a field for the protocol number

8. Depending on which Protocol is defined, the some other fields may appear.
  - **Port Range** - The first field is for the starting value for the port and the second for the ending value for the port range used by the protocol. Both of these values are inclusive.
  - Protocol field - This appears when the **Other** option is chosen. Enter the value of the protocol number for the protocol you wish to use.
9. Toggle the **Log Allowed Traffic** switch to the setting you want. If the slider is gray the option is disabled. If it is colored, it is enabled.
10. Toggle the **Enable this policy** switch to the setting you want. If the slider is gray the option is disabled. If it is colored, it is enabled. By default, this should be enabled
11. Click on the **OK** button to save the policy.

## Object Configuration

As was mentioned earlier, the components of the FortiGate firewall go together like interlocking building blocks. The Firewall objects are a prime example of those building blocks. They are something that can be configured once and then used over and over again to build what you need. They can assist in making the administration of the FortiGate unit easier and more intuitive as well as easier to change. By configuring these objects with their future use in mind as well as building in accurate descriptions the firewall will become almost self documenting. That way, months later when a situation changes, you can take a look at a policy that needs to change and use a different firewall object to adapt to the new situation rather than build everything new from the ground up to accommodate the change.

This chapter includes information about the following Firewall objects:

- [Addresses](#)
- ["Virtual IPs" on page 932](#)
- [IP Pools](#)
- ["Services" on page 944](#)
- ["Firewall schedules" on page 951](#)

## UUID Support

A Universally Unique Identified (UUID) attribute has been added to some firewall objects, so that the logs can record these UUID to be used by a FortiManager or FortiAnalyzer unit. The objects currently include:

- Addresses, both IPv4 and IPv6
- Address Groups, both IPv4 and IPv6
- Virtual IPs, both IPv4 and IPv6
- Virtual IP groups, both IPv4 and IPv6
- Policies, IPv4, IPv6 and IP64

A UUID is a 16-octet (128-bit) number that is represented by 32 lowercase hexadecimal digits. The digits are displayed in five groups separated by hyphens (-). The pattern is 8-4-4-4-12; 36 digits if you include the hyphens.

**Note:** UUID is only supported on large-partition platforms ( $\geq 128\text{M}$ )

---

## Addresses

Firewall addresses define sources and destinations of network traffic and are used when creating policies. When properly set up these firewall objects can be used with great flexibility to make the configuration of firewall policies simpler and more intuitive. The FortiGate unit compares the IP addresses contained in packet headers with a security policy's source and destination addresses to determine if the security policy matches the traffic.

The address categories and the types within those categories on the FortiGate unit can include:

- IPv4 addresses
  - IP address and Netmask
  - IP address range
  - Geography based address
  - Fully Qualified Domain Name (FQDN) address
  - Wildcard FQDN
  - IPv4 Address Group
- IPv6 addresses
  - Subnets
  - IP range
  - IPv6 Address Group
- Multicast addresses
  - Multicast IP range
  - Broadcast subnets
- Proxy Addresses
  - URL Pattern
  - Host Regex Match
  - URL Category
  - HttpMethod
  - User Agent
  - HTTP Header
  - Advanced (Source)
  - Advanced (Destination)
- IP Pools (IPv4)
  - Overload
  - One-to-one
  - Fixed Port Range
  - Port Block Allocation
- IP Pools (IPv6)
- Virtual IP Addresses
  - IPv4
  - IPv6
  - NAT46
  - NAT64

## Interfaces

When setting up an address one of the parameters that is asked for is the interface. This means that the system will expect to see that address only on the interface that you select. You can only select one interface. If you expect that the address may be seen at more than one interface you can choose the “any” interface option. Whenever, possible it is best to choose a more specific interface than the “any” option because in the GUI configuration of firewall policies there is a drop down field that will show the possible addresses that can be used. The drop down will only show those addresses that can be on the interface assigned for that interface in the policy.

Example:

- You have an address called “XYZ”.
- “XYZ” is set to the WAN1 interface because that is the only interface that will be able to access that address.
- When you are selecting a Source Address in the Web-based Manager for a policy that is using the DMZ the address “XYZ” will not be in the drop-down menu.

When there are only 10 or 20 addresses this is not a concern, but if there are a few hundred addresses configured it can make your life easier.

Addresses, address groups, and virtual IPs must have unique names to avoid confusion in firewall policies. If an address is selected in a policy, the address cannot be deleted until it is deselected from the policy.

---

### Addressing Best Practices Tip

The other reason to assign a specific interface to addresses is that it will prevent you from accidentally assigning an address where it will not work properly. Using the example from earlier, if the “XYZ” address was assigned to the “Any” interface instead of WAN1 and you configure the “XYZ” address.

---

### Addressing Best Practices Tip

Don't specify an interface for VIP objects or other address objects that may need to be moved or approached from a different direction. When configuring a VIP you may think that it will only be associated with a single interface, but you may later find that you need to reference it on another interface.

Example: Some web applications require the use of a FQDN rather than an IP address. If you have a VIP set up that works from the Internet to the Internal LAN you won't be able to use that VIP object to access it from an internal LAN interface.

---

## IPv4 Addresses

When creating an IPv4 address there are a number of different types of addresses that can be specified. These include:

- FQDN
- Geography

- IP Range
- IP/Netmask
- Wildcard FQDN

Which one chosen will depend on which method most easily yet accurately describes the addresses that you are trying to include with as few entries as possible based on the information that you have. For instance, if you are trying to describe the addresses of a specific company's web server but if you have no idea of how extensive there web server farm is you would be more likely to use a Fully Qualified Domain Name (FQDN) rather than a specific IP address. On the other hand some computers don't have FQDNs and a specific IP address must be used.

The following is a more comprehensive description of the different types of addresses.

### FQDN Addresses

By using Fully Qualified Domain Name (FQDN) addressing you can take advantage of the dynamic ability of DNS to keep up with address changes without having to manually change the addresses on the FortiGate. FQDN addresses are most often used with external web sites but they can be used for internal web sites as well if there is a trusted DNS server that can be accessed. FQDN addressing also comes in handy for large web sites that may use multiple addresses and load balancers for their web sites. The FortiGate firewall automatically maintains a cached record of all the addresses resolved by the DNS for the FQDN addresses used.

For example, if you were doing this manually and you wanted to have a security policy that involved Google you could track down all of the IP addresses that they use across multiple countries. Using the FQDN address is simpler and more convenient.

When representing hosts by an FQDN, the domain name can also be a subdomain, such as mail.example.com.

Valid FQDN formats include:

- <host\_name>.<top\_level\_domain\_name> such as example.com
- <host\_name>.<second\_level\_domain\_name>.<top\_level\_domain\_name>, such as mail.example.com

When creating FQDN entries it is important to remember that:

- Wildcards are not supported in FQDN address objects
- While there is a level of convention that would imply it, "www.example.com" is not necessarily the same address of "example.com". they will each have their own records on the DNS server.

The FortiGate firewall keeps track of the DNS TTLs so as the entries change on the DNS servers the IP address will effectively be updated for the FortiGate. As long as the FQDN address is used in a security policy, it stores the address in the DNS cache.

There is a possible security downside to using FQDN addresses. Using a fully qualified domain name in a security policy means that your policies are relying on the DNS server to be accurate and correct. DNS servers in the past were not seen as potential targets because the thinking was that there was little of value on them and therefore are often not as well protected as some other network resources. People are becoming more aware that the value of the DNS server is that in many ways it controls where users and computers go on the Internet. Should the DNS server be compromised, security policies requiring domain name resolution may no longer function properly.

### Creating a Fully Qualified Domain Name address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.

3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **FQDN** from the drop down menu.
6. Input the domain name in the **FQDN** field.
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled, the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

### Example: FQDN address

You have to great a policy that will govern traffic that goes to a site that has a number of servers on the Internet. Depending on the traffic or the possibility that one of the servers is down network traffic can go to any one of those sites. The consistent factor is that they all use the same Fully Qualified Domain Name.

- The FQDN of the web site: example.com
- The number of ISP connections off of the FortiGate firewall: 2

### Configuring the address in the GUI

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
2. Fill out the fields with the following information:

Category	Address
Name	BigWebsite.com
Type	FQDN
FQDN	bigwebsite.com
Interface	any
Show in Address List	<enable>
Comments	<Input into this field is optional>

3. Select **OK**.

### Configuring the address in the CLI

```
config firewall address
  edit BigWebsite.com
    set type fqdn
    set associated-interface any
    set fqdn bigwebsite.com
  end
```

### Verification

To verify that the addresses were added correctly:

1. Go to **Firewall Objects > Address > Addresses**. Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall address
edit <the name of the address that you wish to verify>
Show full-configuration
```

### Changing the TTL of a FQDN address

To make sure that the FQDN resolves to the most recent active server you have been asked to make sure that the FortiGate has not cached the address for any longer than 10 minutes.

There is no field for the cached time-to-live in the web-based manager. It is only configurable in the CLI. Enter the following commands:

```
config firewall address
edit BigWebsite.com
set cache-ttl 600
end
```

### Geography Based Addresses

Geography addresses are those determined by country of origin.

This type of address is only available in the IPv4 address category.

### Creating a Geography address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **Geography** from the drop down menu.
6. In the **Country** field, select a single country from the drop down menu.
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

### Example: Geography-based Address

#### Configuring the address in the GUI

Your company is US based and has information on its web site that may be considered information that is not allowed to be sent to embargoed countries. In an effort to help reduce the possibility of sensitive information going to those countries you have be asked to set up addresses for those countries so that they can be block in the firewall policies.

- One of the countries you have been asked to block is Cuba
- You have been asked to comment the addresses so that other administrators will know why they have been created

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
2. Fill out the fields with the following information

Category	Address
Name	Cuba
Type	Geography
Country	Cuba
Interface	any
Visibility	<enable>
Comments	Embargoed

3. Select **OK**.

### Configuring the address in the CLI

Enter the following CLI commands:

```
config firewall address
edit Cuba
    set type geography
    set country CN
    set interface wan1
end
```

### Overrides

It is possible to assign a specific ip address range to a customized country ID. Generally, geographic addressing is done at the VDOM level; it could be considered global if you are using the root VDOM, but the geoip-override setting is a global setting.

```
config system geoip-override
edit "test"
    set country-id "A0"
    config ip-range
        edit 1
            set start-ip 7.7.7.7
            set end-ip 7.7.7.8
        next
        edit 2
            set start-ip 7.7.10.1
            set end-ip 7.7.10.255
        end
    end
```

- While the setting exists in the configuration file, the system assigns the country-id option automatically.
- While you can use "edit 1" and "edit 2", it is simpler to use "edit 0" and let the system automatically assign an ID number.

After creating a customized Country by using geoip-override command, the New country name has been added automatically to the country list and will be available on the Firewall Address Country field.

## Diagnose commands

There are a few diagnose commands used with geographic addresses. The basic syntax is:

```
diagnose firewall ipgeo [country-list | ip-list | ip2country | override |
copyright-notice]
```

Diagnose command	Description
<a href="#">country-list</a>	Listing of all the countries.
<a href="#">ip-list</a>	List of the IP addresses associated with the country
<a href="#">ip2country</a>	Used to determine which country a specific IP address is assigned to.
<a href="#">override</a>	Listing of user defined geography data - items configured by using "config system geoip-override" command.
<a href="#">copyright-notice</a>	Shows the copyright notice.

Click on the diagnose command in the table to connect to the Fortinet Diagnose Wiki page that deals with the command option, to get more information.

## IP Range Addresses

Where the Subnet address is good at representing a standardized group of addresses that are subnets the IP Range type of address can describe a group of addresses while being specific and granular. It does this by specifying a continuous set of IP addresses between one specific IP address and another. While it is most common that this range is with a subnet it is not a requirement. For instance, 192.168.1.0/24 and 192.168.2.0/24 would be 2 separate subnets but if you wanted to describe the top half of one and the bottom half of the other you could describe the range of 192.168.1.128-192.168.2.127. It's also a lot easier than trying to calculate the correct subnet mask.

The format would be:

x.x.x.x-x.x.x.x, such as 192.168.110.100-192.168.110.120

There is a notation that is commonly used and accepted by some devices that follows the format:

x.x.x.[x-x], such as 192.168.110.[100-120]

This format is not recognized in FortiOS 5.2 as a valid IP Range.

### Creating a IP Range address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**
3. In the **Category** field, chose **Address**(IPv4 addresses) or **IPv6 Address**.
4. Input a **Name** for the address object.
5. In the **Type** field, select **IP Range** from the drop down menu.
6. In the **Subnet / IP Range** field, enter the range of addresses in the following format: x.x.x.x-x.x.x.x (no spaces)
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu. (This setting is not available for IPv6 addresses)
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

### Example

Example of a IP Range address for a group of computers set aside for guests on the company network.

Field	Value
<b>Category</b>	<b>Address or IPv6 Address</b>
<b>Name</b>	Guest_users
<b>Type</b>	<b>IP Range</b>
<b>Subnet / IP Range</b>	192.168.100.200-192.168.100.240
<b>Interface</b>	<b>Port1</b>
<b>Show in Address List</b>	[on]
<b>Comments</b>	Computers on the 1st floor used by guests for Internet access.

IP Range addresses can be configured for both IPv4 and IPv6 addresses. The only differences in creating an IPv6 IP Range address is that you would choose IPv6 Address for the Category and the syntax of the address in the Subnet/IP Range field would be in the format of 2001:0db8:0000:0002:0:0:0:20-2001:0db8:0000:0004:0:0:0:20

## IP / Netmask Addresses

The subnet type of address is expressed using a host address and a subnet mask. From a strictly mathematical stand point this is the most flexible of the types because the address can refer to as little one individual address or as many as all of the available addresses.

It is usually used when referring to your own internal addresses because you know what they are and they are usually administered in groups that are nicely differentiated along the lines of the old A, B, and C classes of IPv4 addresses. They are also addresses that are not likely to change with the changing of Internet Service Providers (ISP).

When representing hosts by an IP address with a netmask, the IP address can represent one or more hosts. For example, a firewall address can be:

- A single host such as a single computer with the address 192.45.46.45
- A range of hosts such as all of the hosts on the subnet 192.45.46.1 to 192.45.46.255
- All hosts, represented by 0.0.0.0 which matches any IP address

The netmask corresponds to the subnet class of the address being added, and can be represented in either dotted decimal or CIDR format. The FortiGate unit automatically converts CIDR formatted netmasks to dotted decimal format. Example formats:

- Netmask for a class A subnet of 16,777,214 usable addresses: 255.0.0.0, or /8
- Netmask for a class B subnet of 65,534 usable addresses: 255.255.0.0, or /16
- Netmask for a class C subnet of 254 usable addresses: 255.255.255.0, or /24
- Netmask for subnetted class C of 126 usable addresses: 255.255.255.128, or /25
- Netmask for subnetted class C of 62 usable addresses: 255.255.255.128, or /26
- Netmask for subnetted class C of 30 usable addresses: 255.255.255.128, or /27
- Netmask for subnetted class C of 14 usable addresses: 255.255.255.128, or /28
- Netmask for subnetted class C of 6 usable addresses: 255.255.255.128, or /29
- Netmask for subnetted class C of 2 usable addresses: 255.255.255.128, or /30
- Netmask for a single computer: 255.255.255.255, or /32
- Netmask used with 0.0.0.0 to include all IP addresses: 0.0.0.0, or /0

So for a single host or subnet the valid format of IP address and netmask could be either:

x.x.x.x/x.x.x.x, such as 192.168.1.0/255.255.255.0

or

x.x.x.x/x, such as 192.168.1.0/24

## Static Route Configuration

A setting that is found in the IP/Netmask address type that is not found in the other address types is the enabling or disabling of **Static Route Configuration**. Enabling this feature includes the address in the listing of named addresses when setting up a static route.

### To use in the GUI

1. Enable the **Static Route Configuration** in the address.
2. Go to **Network > Static Routes** and create a new route.
3. For a **Destination** type, choose **Named Address**.

4. Using the drop down menu, enter the name of the address object in the field just underneath the **Destination** type options.
5. Fill out the other information relevant to the route
6. Select the **OK** button

#### To enable in the CLI:

```
config firewall address
  edit <address_name>
    set allow-routing enable
  end
```

#### Creating a Subnet address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **IP/Netmask** from the drop down menu.
6. In the **Subnet/IP Range** field, enter the address and subnet mask according to the format x.x.x.x/x.x.x.x or the short hand format of x.x.x.x/x
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Select the desired on/off toggle setting for **Static Route Configuration**.
10. Input any additional information in the **Comments** field.
11. Press **OK**.

#### Example

Example of a Subnet address for a database server on the DMZ:

Field	Value
<b>Category</b>	<b>Address</b>
<b>Name</b>	DB_server_1
<b>Type</b>	<b>IP/Netmask</b>
<b>Subnet/IP Range</b>	United States
<b>Interface</b>	<b>any</b>
<b>Show in Address List</b>	[on]
<b>Static Route Configuration</b>	[off]
<b>Comments</b>	

## Wildcard FQDN

There are a number of companies that use secondary and even tertiary domain names or FQDNs for their websites. Wildcard FQDN addresses are to ease the administrative overhead in cases where this occurs. Sometimes its as simple as sites that still use www. as a prefix for their domain name. If you don't know whether or not the www is being used it's simpler to use a wildcard and include all of the possibilities whether it be example.com, www.example.com or even ftp.example.com.

The following wildcard character instances are supported in wildcard FQDN addresses:

- "?" character
- "\*" character in the middle of a phrase
- The "?\*" combination

Wildcard FQDN addresses do not resolve to a specific set of IP addresses in the same way that a normal FQDN address does. They are intended for use in SSL exemptions and should not be used as source or destination addresses in policies.

## Creating a Fully Qualified Domain Name address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**
3. In the **Category** field, chose **Address**. (This is for IPv4 addresses.)
4. Input a **Name** for the address object.
5. In the **Type** field, select **Wildcard FQDN** from the drop down menu.
6. Input the domain name in the **Wildcard FQDN** field.
7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

## Example

Example of a FQDN address for a remote FTP server used by Accounting team:

Field	Value
<b>Category</b>	<b>Address</b>
<b>Name</b>	Example.com_servers
<b>Type</b>	<b>Wildcard FQDN</b>
<b>Wildcard FQDN</b>	*.example.com
<b>Interface</b>	<b>any</b>
<b>Show in Address List</b>	[on]

Field	Value
Comments	Secondary and tertiary domain names for example.com

## IPv6 Addresses

When creating an IPv6 address there are a number of different types of addresses that can be specified. These include:

- Subnet
- IP Range - the details of this type of address are the same as the IPv4 version of this type

The IPv6 addresses don't yet have the versatility of the IPv4 address in that they don't have things like geography based or FQDN address but as IPv6 becomes more mainstream this should change.

### Subnet Addresses

The Subnet Address type is one that is only used in reference to IPv6 addresses. It represents an IPv6 address subnet. This means that the address will likely be a series of hexadecimal characters followed by a double colon, followed by a "/", and then a number less than 128 to indicate the size of the subnet. An example would be:

fd5e:3c59:35ce:f67e::/64

- The hexadecimal characters represent the IPv6 subnet address.
- The "::" indicates 0's from that point to the left. In an actual address for a computer, the hexadecimal characters that would take the place of these zeros would represent the device address on the subnet.
- /xx, in this case /64 represents the number of bits in the subnet. This will make a range that can potentially include 18,446,744,073,709,551,616 addresses. For those wanting to use English rather than math, that is 18 Quintillion.

### Creating a Subnet address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**
3. In the **Category** field, chose **IPv6 Address**.
4. Input a **Name** for the address object.
5. In the **Type** field, select **Subnet** from the drop down menu.
6. In the **Subnet / IP Range** field, enter the range of addresses in IPv6 format (no spaces)
7. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
8. Input any additional information in the **Comments** field.
9. Press **OK**.

### Example

Example of a IP Range address for a group of computers set aside for guests on the company network.

Field	Value
Category	IPv6 Address

Field	Value
Name	IPv6_Guest_user_range
Type	Subnet
Subnet / IP Range	fd5e:3c59:35ce:f67e::/64
Show in Address List	[on]
Comments	

## Multicast Addresses

Multicast addressing defines a specific range of address values set aside for them. Therefore all IPv4 multicast addresses should be between 224.0.0.0 and 239.255.255.255.

More information on the concepts behind Multicast addressing can be found in the Multicast Forwarding section.

## Multicast IP Range

This type of address will allow multicast broadcasts to a specified range of addresses.

### Creating a Multicast IP Range address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**.
  - If you use the down arrow next to **Create New**, select **Address**.
3. Choose the **Category, Multicast Address**
4. Input a **Name** for the address object.
5. Select the **Type, Multicast IP Range** from the dropdown menu.
6. Enter the value for the **Multicast IP Range**
7. Select the **Interface** from the dropdown menu.
8. Enable the **Show in Address List** function
9. Input any additional information in the **Comments** field.
10. Press **OK**.

### Example: Multicast IP Range Address

The company has a large high tech campus that has monitors in many of its meeting rooms. It is common practice for company wide notifications of importance to be done in a streaming video format with the CEO of the company addressing everyone at once.

The video is High Definition quality so takes up a lot of bandwidth. To minimize the impact on the network the network administrators have set things up to allow the use of multicasting to the monitors for these notifications. Now it has to be set up on the FortiGate firewall to allow the traffic.

- The range being used for the multicast is 239.5.5.10 to 239.5.5.200
  - The interface on this FortiGate firewall will be on port 9
1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address**.
  2. Fill out the fields with the following information

<b>Category</b>	Multicast Address
<b>Name</b>	Meeting_Room_Displays
<b>Type</b>	Multicast IP Range
<b>Multicast IP Range</b>	239.5.5.10-239.5.5.200
<b>Interface</b>	port9
<b>Show in Address List</b>	<enable>
<b>Comments</b>	<Input into this field is optional>

3. Select **OK**.
4. Enter the following CLI command:

```
config firewall multicast-address
edit "meeting_room_display"
set type multicastrange
set associated-interface "port9"
set start-ip 239.5.5.10
set end-ip 239.5.5.200
set visibility enable
next
end
```

**To verify that the address range was added correctly:**

1. Go to **Policy & Objects > Objects > Addresses**. Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall multicast-address
edit <the name of the address that you wish to verify>
Show full-configuration
```

### Broadcast Subnet

This type of address will allow multicast broadcast to every node on a subnet.

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Multicast Address**.
4. Input a **Name** for the address object.
5. In the **Type** field, select **Broadcast Subnet** from the drop down menu.
6. In the **Broadcast Subnet** field enter the address and subnet mask according to the format x.x.x.x/x.x.x.x or the short hand format of x.x.x.x/x. (Remember, it needs to be within the appropriate IP range 224.0.0.0 to 239.255.255.255)

7. In the **Interface** field, leave as the default **any** or select a specific interface from the drop down menu.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Press **OK**.

### Example

Field	Value
Category	Broadcast Subnet
Name	Corpnet-B
Type	Broadcast Subnet
Broadcast Subnet	224.5.5.0/24
Interface	any
Show in Address List	[on]
Comments	Corporate Network devices - Broadcast Group B

### Multicast IP addresses

Multicast uses the Class D address space. The 224.0.0.0 to 239.255.255.255 IP address range is reserved for multicast groups. The multicast address range applies to multicast groups, not to the originators of multicast packets. The following table lists the reserved multicast address ranges and describes what they are reserved for:

### Reserved Multicast address ranges

Reserved Address Range	Use	Notes
224.0.0.0 to 224.0.0.255	Used for network protocols on local networks. For more information, see RFC 1700.	In this range, packets are not forwarded by the router but remain on the local network. They have a Time to Live (TTL) of 1. These addresses are used for communicating routing information.
224.0.1.0 to 238.255.255.255	Global addresses used for multicasting data between organizations and across the Internet. For more information, see RFC 1700.	Some of these addresses are reserved, for example, 224.0.1.1 is used for Network Time Protocol (NTP).
239.0.0.0 to 239.255.255.255	Limited scope addresses used for local groups and organizations. For more information, see RFC 2365.	Routers are configured with filters to prevent multicasts to these addresses from leaving the local system.

Creating multicast security policies requires multicast firewall addresses. You can add multicast firewall addresses by going to **Firewall Objects > Address > Addresses** and selecting **Create New > Multicast Address**. The factory default configuration includes multicast addresses for Bonjour (224.0.0.251-224.0.0.251), EIGRP (224.0.0.10-224.0.0.100), OSPF (224.0.0.5-224.0.0.60), all\_hosts (224.0.0.1-224.0.0.1), and all\_routers (224.0.0.2-224.0.0.2).

## Proxy Addresses

This category of address is different from the other addresses in that it is not designed to be used in the normal firewall policy configuration. It is intended to be used only with explicit web proxies.

In some respects they can be like a FQDN addresses in that they refer to an alpha-numeric string that is assigned to an IP address, but then goes an additional level of granularity by using additional information and criteria to further specify locations or types of traffic within the website itself. In depth information on Explicit Proxy Addressing can be found in [WAN Optimization](#), but it is worth laying out the steps of how to create an address object for this category.

### Creating a Proxy address

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**. A drop down menu is displayed. Select **Address**.
3. In the **Category** field, chose **Proxy Address**.
4. Input a **Name** for the address object.
5. For the **Type** field, select one of the options from the drop down menu.

Within the Explicit Proxy Address category there are 8 types of addresses. Each of these types will have associated field(s) that also need to have values entered to make the object specific to it's address.

#### Type = URL Pattern

- In the **Host** field, choose from drop down menu
- In the **URL Path Regex** field, enter the appropriate string

#### Host Regex Match

- In the **Host Regex Pattern** field, enter the appropriate string

#### URL Category

- In the **Host** field, choose from drop down menu
- In the **URL Category** field, choose from drop down menu

#### HTTP Method

- In the **Host** field, choose from drop down menu
- In the **Request Method** field, choose from drop down menu

The options are:

- CONNECT
- DELETE
- GET

- HEAD
- OPTIONS
- POST
- PUT
- TRACE

### User Agent

- In the **Host** field, choose from drop down menu
- In the **User Agent** field, choose from drop down menu

The options are:

- Apple Safari
- Google Chrome
- Microsoft Internet Explorer or Spartan
- Mozilla Firefox
- Other browsers

### HTTP Header

- In the **Host** field, choose from drop down menu
- In the **Header Name** field, enter the appropriate string value
- In the **Header Regex** field, enter the appropriate string value

### Advanced (Source)

- In the **Host** field, choose from drop down menu
- In the **Request Method** field, choose from drop down menu (see **HTTP Method** type for option list)
- In the **User Agent** field, choose from drop down menu (see **User Agent** type for option list)
- In the **Header Group** table, create, edit or delete **Header Name** strings and associated **Header Regex** strings

### Advance (Destination)

- In the **Host** field, choose from drop down menu
- In the **Host Regex Pattern** field, enter the appropriate string
- In the **URL Category** field, choose from drop down menu

6. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled the address will appear in drop down menus where it is an option.
7. Input any additional information in the **Comments** field.
8. Press **OK**.

### Proxy Address Groups

To create a Proxy address group:

1. Go to **Policy & Objects > Addresses**.
2. Click on **+ Create New** to get the drop down menu. Select **Address Group**.

3. In the **Category** field, choose **Proxy Group**.
4. Fill in a descriptive name in the **Group Name** field.
5. If you wish, use the **Change** link to change the **Color** of icons in the GUI. There are 32 color options.
6. In the **Type** field, select whether the group will be a **Source Group** (composed of source addresses) or a **Destination Group** (composed of destination addresses).
7. Select anywhere in the **Members** field to bring forth the pane of potential members for selection to the group.
8. Select the desired on/off toggle setting for **Show in Address List**. If the setting is enabled, the address will appear in drop down menus where it is an option.
9. Input any additional information in the **Comments** field.
10. Click on **OK**.

## Internet Services

In FortiOS 5.4, support was added for Internet Service objects which could be used with **FortiView**, **Logging**, **Routing** and **WAN Load Balancing**. Now they can be added to firewall policies as well.

There is an either or relationship between Internet Service objects and destination address and service combinations in firewall policies. This means that a destination address and service can be specified in the policy OR an Internet service, not both.

## CLI

The related CLI options/syntax are:

```
config firewall policy
edit 1
set internet-service 1 5 10
set internet-service-custom test
set internet-service-negate [enable|disable]
end
```

## GUI

In the policy listing page you will notice that is an Internet Service object is used, it will be found in both the **Destination** and **Service** column.

In the policy editing page the **Destination Address**, now **Destination** field now has two types, **Address** and **Internet Service**.

New Policy		Select Entries
Name	Citrix access	Address <b>Internet Service</b>
Incoming Interface	port1	Search
Outgoing Interface	port2	Citrix-FTP(S)
Source	all	Citrix-IMAP(S)
Destination	<ul style="list-style-type: none"> <li>Citrix-DNS</li> <li>Citrix-FTP(S)</li> <li>Citrix-IMAP(S)</li> <li>Citrix-NetBIOS.Name.Service</li> <li>Citrix-NetBIOS.Session.Service</li> <li>Citrix-SMTP(S)</li> <li>Citrix-SSH</li> <li>Citrix-Web</li> <li>CNN-FTP(S)</li> </ul>	<ul style="list-style-type: none"> <li>Citrix-NetBIOS.Name.Service</li> <li>Citrix-NetBIOS.Session.Service</li> <li><b>Citrix-SMTP(S)</b></li> <li>Citrix-SSH</li> <li>Citrix-Web</li> <li>CNN-FTP(S)</li> <li>CNN-SMTP(S)</li> <li>Dropbox-DNS</li> <li>Dropbox-NetBIOS.Name.Service</li> </ul>

## Address Groups

Address groups are designed for ease of use in the administration of the device. If you have a number of addresses or address ranges that will commonly be treated the same or require the same security policies, you can put them into address groups, rather than entering multiple individual addresses in each policy refers to them.

The use of groups is not required. If you have a number of different addresses you could add them individually to a policy and the FortiGate firewall will process them just as quickly and efficiently as if they were in a group, but the chances are that if you have used a group once you could need to use it again and depending on the number of addresses involved entering them individually for each policy can become tedious and the likelihood of an address being missed becomes greater. If you have a number of policies using that combination of addresses it is much easier to add or subtract addresses from the group than to try and remember all of the firewall policies that combination of addresses was used in. With the group, you only have to make the one edit and it is used by any firewall policy using that address group.

Because security policies require addresses with homogenous network interfaces, address groups should contain only addresses bound to the same network interface, or to Any.

For example, if address 1.1.1.1 is associated with port1, and address 2.2.2.2 is associated with port2, they cannot be in the same group. However, if 1.1.1.1 and 2.2.2.2 are configured with an interface of Any, they can be grouped, even if the addresses involve different networks.

There are 3 Categories of Address groups to choose from:

- IPv4 Group
- IPv6 Group
- Proxy Group

You cannot mix different categories of addresses within a group, so whether or not it makes sense from an administrative purpose to group certain addresses together, if some are IPv4 and some are IPv6, it cannot be done.

## Creating an Address Group

1. Go to **Policy & Objects > Addresses**.
2. Select the down arrow next to **Create New**, select **Address Group**.
3. Choose the **Category**, that is applicable to the proposed selection of addresses.
4. Input a **Group Name** for the address object.

Depending on which **Category** has been chosen the configurations will differ slightly

### IPv4 Group

1. Select the "+" in the **Members** field. You can select members of the group from the window that slides out from the left of the screen. It is possible to select more than 1 entry. Select the "X" icon in the field to remove an entry.
2. Select the desired on/off toggle setting for **Show in Address List**.
3. Select the desired on/off toggle setting for **Static Route Configuration**.

### IPv6 Group

1. Select the "+" in the **Members** field. You can select members of the group from the window that slides out from the left of the screen. It is possible to select more than 1 entry. Select the "X" icon in the field to remove an entry.
2. Select the desired on/off toggle setting for **Show in Address List**.

### Proxy Group

1. Select which Type, either **Source Group** or **Destination Group**.
2. Select the "+" in the **Members** field. You can select members of the group from the window that slides out from the left of the screen. It is possible to select more than 1 entry. Select the "X" icon in the field to remove an entry.
3. Select the desired on/off toggle setting for **Show in Address List**.

Irrespective of the Category the groups all have the same final configuration options:

1. Input any additional information in the **Comments** field.
2. Press **OK**.

## UUID Support

### Syntax:

```
config firewall {address|addres6|addgrp|addgrp6}
edit 1
    set uuid <example uuid: 8289ef80-f879-51e2-20dd-fa62c5c51f44>
    next
end
```

## Virtual IPs

The mapping of a specific IP address to another specific IP address is usually referred to as Destination NAT. When the Central NAT Table is not being used, FortiOS calls this a Virtual IP Address, sometimes referred to as a VIP. FortiOS uses a DNAT or Virtual IP address to map an External IP address to an IP address. This address does not have to be an individual host, it can also be an address range. This mapping can include all TCP/UDP ports or if Port Forwarding is enabled it will only refer to the specific ports configured. Because, the Central NAT table is disabled by default the term Virtual IP address or VIP will be used predominantly.

Virtual IP addresses are typically used to NAT external or Public IP addresses to internal or Private IP addresses. Using a Virtual IP address between 2 internal Interfaces made up of Private IP addresses is possible but there is rarely a reason to do so as the 2 networks can just use the IP addresses of the networks without the need for any address translation. Using a Virtual IP address for traffic going from the inside to the Internet is even less likely to be a requirement, but it is supported.

Something that needs to be considered when there are multiple Public IP addresses on the external interface(s) is that when a Virtual IP address is used without Port Forwarding enabled there is a reciprocal effect as far as traffic flow is concerned. Normally, on a firewall policy where NAT is enabled, for outgoing traffic the internal address is translated to the Public address that is assigned to the FortiGate, but if there is a Virtual IP address with no port forwarding enabled, then the Internal IP address in the Mapped field would be translated to the IP address configured as the External Address in the VIP settings.

### Example

- The assigned External address (WAN1) of the FortiGate unit is 172.12.96.3 with a subnet mask of 255.255.255.128
- There is a Virtual IP address set up to map the external address 172.12.96.127 on WAN1 to the internal IP address of 192.168.1.127
- Port Forwarding is not enabled because you want all allowed traffic going to the external IP address to go to this server.

In this case any outbound traffic from 192.168.1.127 will go out on WAN1 with the IP address of 172.12.96.127 as the source IP address.

In terms of actually using the Virtual IP address, they would be using in the security policies in the same places that other addresses would be used, usually as a Destination Address.

### UUID Support for VIP

UUID is now supported in for virtual IPs and virtual IP groups. This includes virtual IPs for IPv4, IPv6, NAT46, and NAT64. To view the UUID for these objects in a FortiGate unit's logs, log-uuid must be set to extended mode, rather than policy-only (which only shows the policy UUID in a traffic log). UUID can only be configured through the CLI

### Syntax

```
config sys global
    set log-uuid {disable | policy-only | extended}
end
```

There is another type of address that the term “virtual IP address” commonly refers to which is used in load balancing and other similar configurations. In those cases, a number of devices share a separately created virtual IP address that can be sent to multiple possible devices. In FortiOS these are referred to as Virtual Servers and are configured in the “Load Balance” section.

If Central-NAT is enabled in the CLI the GUI will be different.

Instead of **VIP Type**, the field label will be **DNAT & VIP Type**

Instead of **IPv4** the option will be **IPv4 DNAT**

There will also be the addition setting of **Source Interface Filter**.

Commands to set `central-nat`:

```
config system settings
  set central-nat [enable | disable]
end
```

## Creating a Virtual IP

1. Go to **Policy & Objects > Virtual IPs**.
2. Select **Create New**. A drop down menu is displayed. Select **Virtual IP**.
3. From the **VIP Type** options, choose an applicable type based on the IP addressing involved. Which is chosen will depend on which of the IP version networks is on the external interface of the FortiGate unit and which is on the internal interface.

The available options are:

- **IPv4** - IPv4 on both sides of the FortiGate Unit.
  - **IPv6** - IPv6 on both sides of the FortiGate Unit.
  - **NAT46** - Going from an IPv4 Network to an IPv6 Network.
  - **NAT64** - Going from an IPv6 Network to an IPv4 Network.
4. In the **Name** field, input a unique identifier for the Virtual IP.
  5. Input any additional information in the **Comments** field.
  6. The **Color** of the icons that represent the object in the GUI can be changed by clicking on the **[Change]** link and choosing from the 32 colors.

Because the configuration differs slightly for each type the next steps will be under a separate heading based on the type of the VIP

## Configuring a VIP for IPv4

In the **Network** section:

7. If an IPv4 type of Virtual IP, select the **Interface** setting.  
Using the drop down menu for the Interface Field, choose the incoming interface for the traffic.  
The IPv4 VIP Type is the only one that uses this field. This is a legacy function from previous versions so that

they can be upgraded without complicated reconfiguration. The External IP address, which is a required field, tells the unit which interface to use so it is perfectly acceptable to choose **"any"** as the interface. In some configurations, if the Interface field is not set to **"any"** the Virtual IP object will not one of the displayed options when choosing a destination address.

8. Configure the **External IP Address/Range**.

There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. The format of the address will depend on the **VIP Type** option that was selected.

9. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to.

There are two fields. If there is a single IP address, use that address in both fields. The format of the address will depend on the **VIP Type** option that was selected.

In the **Optional Filters**

10. Disable/Enable the **Optional Filters**.

If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.

11. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.

- **Source IP** - Use the standard format for a single IP address
- **Range** - Enter the first and last members of the range
- **Subnet** - Enter the IP address of the broadcast address for the subnet.

To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.

12. To specify an allowed Service, toggle the **Services** option to enabled. Set the **Services** parameter by selecting the field with the "+" in the field. This will slide a window out from the right. Single or multiple options can be selected by highlighting the services wanted, unless the **ALL** option is chosen, in which case it will be the only option. For more information on services, check the Firewall Objects section called [Services and TCP ports](#).

13. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.

14. Select the **Protocol** from

- **TCP**
- **UDP**
- **SCTP**
- **ICMP**

15. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.

16. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.

17. Press **OK**.

## Example

This example is for a VIP that is being used to direct traffic from the external IP address to a web server on the internal network. The web server is for company use only. The company's public facing web server already used port 80 and there is only one IP external IP address so the traffic for this server is being listened for on port 8080 of the external interface and being sent to port 80 on the internal host.

Field	Value
<b>VIP Type</b>	IPv4
<b>Name</b>	Internal_Webserver
<b>Comments</b>	Web server with Collaboration tools for Corporate employees
<b>Interface</b>	Any
<b>External IP Address/Range</b>	172.13.100.27 <this would normally be a public IP address>
<b>Mapped IP Address/Range</b>	192.168.34.150
<b>Optional Filters</b>	enabled
<b>Source Address Filter</b>	<list of IP addresses of remote users>
<b>Services</b>	enabled with HTTP in the list
<b>Port Forwarding</b>	enabled
<b>Map to Port</b>	80 - 80

## Configuring a VIP for IPv6

In the **Network** section:

### 7. Configure the **External IP Address/Range**.

There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. Enter the address in the standard IPv6 format.

### 8. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to.

There are two fields. If there is a single IP address, use that address in both fields. Enter the address in the standard IPv6 format.

In the **Optional Filters**

### 9. Disable/Enable the **Optional Filters**.

If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.

10. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.
  - **Source IP** - Use the standard format for a single IP address
  - **Range** - Enter the first and last members of the range
  - **Subnet** - Enter the IP address of the broadcast address for the subnet.  
To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.
12. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.
13. Select the **Protocol** from
  - **TCP**
  - **UDP**
  - **SCTP**
14. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
15. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
16. Press **OK**.

### Configuring a VIP for NAT46

In the **Network** section:

7. Configure the **External IP Address/Range**.  
There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. Enter the address in the standard IPv4 format.
8. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to.  
There are two fields. If there is a single IP address, use that address in both fields. Enter the address in the standard IPv6 format.

In the **Optional Filters**

9. Disable/Enable the **Optional Filters**.  
If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.
10. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.
  - **Source IP** - Use the standard format for a single IP address
  - **Range** - Enter the first and last members of the range
  - **Subnet** - Enter the IP address of the broadcast address for the subnet.

To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.

12. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.
13. Select the **Protocol** from
  - **TCP**
  - **UDP**
14. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
15. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
16. Press **OK**.

### Configuring a VIP for NAT64

In the **Network** section:

7. Configure the **External IP Address/Range**.

There are two fields. If there is a single IP address, use that address in both fields. This will be the address on the outside of the network that is usually the public address of the server. Enter the address in the standard IPv6 format.

8. Configure the **Mapped IP Address/Range**. This will be the address that the traffic is being directed to.

There are two fields. If there is a single IP address, use that address in both fields. Enter the address in the standard IPv4 format.

In the **Optional Filters**

9. Disable/Enable the **Optional Filters**.

If only specific IP addresses and/or services are allowed to be the source for traffic using the VIP, enable the **Optional Filters**.
10. To specify an allowed address enter the value in the field labeled **Source Address**. The value can be formatted in three different ways.
  - **Source IP** - Use the standard format for a single IP address
  - **Range** - Enter the first and last members of the range
  - **Subnet** - Enter the IP address of the broadcast address for the subnet.

To add additional addresses, click on the "+" below the last field with an address. To subtract an address, click on the "X" next to the field you wish to delete.
12. Disable/Enable **Port Forwarding**. If only the traffic for a specific port or port range is being forwarded, enable this setting.
13. Select the **Protocol** from

- TCP
- UDP

14. Configure the **External Service Port**. This is the port(s) on the external interface of the FortiGate (the destination port in the header of the packets). The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
15. Configure the setting **Map to Port**. This will be the listening port on the device located on the internal side of the network. It does not have to be the same as the **External Service Port**. The first field is for the first port in the range the second is for the last port in the range. As you enter a value in the first field, the second field will auto populate with the same number, working on the premise that a single port is common. Just edit the second field to extend the range.
16. Press **OK**.

## FQDN in VIPs

Instead of mapping to an IP address a VIP can use a FQDN(Fully Qualified Domain Name). This has to be configured in the CLI and the FQDN must be an address object that is already configured in the address listing.

The syntax for using a FQDN is:

```
config firewall vip
edit <VIP id>
set type fqdn
set mapped-addr <FQDN address object>
end
```

## Dynamic VIP according to DNS translation

When a dynamic virtual IP is used in a policy, the dynamic DNS translation table is installed along with the dynamic NAT translation table into the kernel. All matched DNS responses will be translated and recorded regardless if they hit the policy. When a client request hits the policy, dynamic NAT translation will occur if it matches a record, otherwise the traffic will be blocked.

### Syntax

```
config firewall vip
edit "1"
set type dns-translation
set extip 192.168.0.1-192.168.0.100
set extintf "dmz"
set dns-mapping-ttl 604800
set mappedip "3.3.3.0/24" "4.0.0.0/24"
end
end
```

## Virtual IP Groups

Just like other address, Virtual IP addresses can be organized into groups for ease of administration. If you have multiple virtual IPs that are likely to be associated to common firewall policies rather than add them individually to each of the policies you can add the instead. That way, if the members of the group change then any changes made to the group will propagate to all of the policies using that group.

When using a Virtual IP address group the firewall policy will take into account all of the configured parameters of the Virtual IPs: IP addresses, Ports and port types.

### Creating a Virtual IP Group

1. Go to **Policy & Objects > Virtual IPs**.
2. Select **Create New**. A drop down menu is displayed. Select **Virtual IP Group**.
3. Select the **Type** fo VIP group you wish to create.

The options available are:

- **IPv4** - IPv4 on both sides of the FortiGate Unit.
- **IPv6** - IPv6 on both sides of the FortiGate Unit.
- **NAT46** - Going from an IPv4 Network to an IPv6 Network.
- **NAT64** - Going from an IPv6 Network to an IPv4 Network.

Which is chosen will depend on which of the IP version networks is on the external interface of the FortiGate unit and which is on the internal interface. The options will be:

4. Enter a unique identifier for the group in the **Name** field.
5. Enter any additional information in the **Comments** field.
6. If you wish, use the **Change** link to change the **Color** of icons in the GUI. There are 32 color options.
7. If the **Type** is **IPv4**, the **Interface** field will be available. Use the drop-down menu to select the interface if all of the VIPs are on the same interface. If any of the VIPs are on different interfaces or if any of them are associated with the "any" option, choose the any option for the group.
8. Select anywhere in the **Members** field to bring forth the pane of potential members for selection to the group.
9. Press **OK**.

### Configuring IP pools

An IP pool is essentially one in which the IP address that is assigned to the sending computer is not known until the session is created, therefore at the very least it will have to be a pool of at least 2 potential addresses. A quick example would be an IP pool for users of a VPN. IP pools are based upon the version of IP determined by the interface that they are associated with so as expected there are two types of IP pools that can be configured:

- ["Creating a IPv4 Pool" on page 939](#)
- ["Creating a IPv6 Pool" on page 943](#)

Because of the differences in the configuration for the two types of pools, instructions for configuring them will be done separately.

#### Creating a IPv4 Pool

1. Go to **Policy & Objects > IP Pools**.
2. Select **Create New**.
3. In the **IP Pool Type** field choose **IPv4 Pool**
4. Enter a name in the **Name** field for the new service
5. Include any description you would like in the **Comments** field
6. In the **Type** field choose between:
  - **Overload**
  - **One-to-One**
  - **Fixed Port Range**
  - **Port Block Allocation**

At this point the configurations can start to differ based on the type of type of pool.

For more information on the different types of IP pools, check [IP Pools](#) in the Concepts section.

### Overload

7. For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.
8. Enable the **ARP Reply** field by making sure there is a check in the box
9. Select **OK**

### Overload Example for GUI

In this example, the Sales team needs to connect to an Application Service Provider that does the accounting for the company. As a security measure, the ASP only accepts traffic from a white list of IP addresses. There is 1 public IP address of the company on that list. The Sales team consists of 40 people, so they need to share. The external interface is wan1.

Field	Value
IP Pool Type	IPv4 Pool
Name	Sales_Team
Comments	For the Sales team to use to connect to the Accounting ASP
Type	Overload (This is the default)
External IP Range	10.23.56.20 - 10.23.56.20
ARP Reply	enabled

### Overload Example for CLI

```
config firewall ippool
edit Sales_Team
    set comments "For the Sales team to use to connect to the Accounting ASP"
    set type overload
    set startip 10.23.56.20
    set endip 10.23.56.20
    set arp-reply enable
    set arp-intf wan1
end
```

### One-to-one

7. For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.
8. Enable the **ARP Reply** field by making sure there is a check in the box.
9. Select **OK**

### One-to-one Example for GUI

In this example, the external IP address of the mail server is part of a range assigned to the company but not the one that is assigned to the Internet facing interface. A VIP has been set up but in order to properly resolve Reverse DNS lookups the mail server always has to use a specific IP address. The external interface is wan1.

Field	Value
IP Pool Type	IPv4 Pool
Name	Mail-Server
Comments	So the the correct IP address is resolved on Reverse DNS look ups of the mail server.
Type	One-to-one
External IP Range	10.23.56.21 - 10.23.56.21
ARP Reply	enabled

### One-to-one Example for CLI

```
config firewall ippool
  edit Mail-Server
    set comments "So the the correct IP address is resolved on reverse DNS look ups of
      the mail server."
    set type one-to-one
    set startip 10.23.56.21
    set endip 10.23.56.21
    set arp-reply enable
    set arp-intf wan1
  end
```

### Fixed Port Range

7. For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.
8. For the **Internal IP Range** fields, enter the lowest and highest addresses in the range.
9. Enable the **ARP Reply** field by making sure there is a check in the box
10. Select **OK**

### Fixed Port Range Example for GUI

In this example, the company has a range of 10 IP address that they want to be used by employees on a specific subnet for NATing. The external interface is wan1.

Field	Value
IP Pool Type	IPv4 Pool
Name	IPPool-3

Field	Value
Comments	IP range to be used by outgoing traffic
Type	Fixed Port Range
External IP Range	10.23.56.22 - 10.23.56.31
Internal IP Range	192.168.23.1 - 192.168.23.254
ARP Reply	enabled

### Fixed Port Range Example for CLI

```
config firewall ippool
edit IPPool-3
    set comments "So the the correct IP address is resolved on reverse DNS look ups of
        the mail server."
    set type fixed-port-range
    set startip 10.23.56.22
    set endip 10.23.56.31
    set source-startip 192.168.23.1
    set source-endip 192.168.23.254
    set arp-reply enable
    set arp-intf wan1
end
```

### Port Block Allocation

- For the **External IP Range** fields, enter the lowest and highest addresses in the range. If you only want a single address used, enter the same address in both fields.
- In the **Block Size** field, either type in the value or use the up or down arrows to set the value of the block size.
- In the **Blocks Per User** field, either type in the value or use the up or down arrows to set the value for the number of blocks per user.
- Enable the **ARP Reply** field by making sure there is a check in the box
- Select **OK**

### Port Block Allocation Example for GUI

In this example, a small ISP is setting up NATing for its clients, but to be fair it is putting some restrictions on the number of connections each client can have so that no one hogs all of the possible ports and addresses. The external interface is port12.

Field	Value
IP Pool Type	IPv4 Pool
Name	Client-IPPool
Comments	IP Pool for clients to access the Internet

Field	Value
Type	Port Block Allocation
External IP Range	10.23.75.5 - 10.23.75.200
Block Size	64
Blocks Per User	8
ARP Reply	enabled

### Port Block Allocation Example for CLI

```
config firewall ippool
edit Client-IPPool
set comments "IP Pool for clients to access the Internet"
set type port-block-allocation
set startip 10.23.75.5
set endip 10.23.75.200
set block-size 64
set num-blocks-per-user 8
set permit-any-host disable
set arp-intf wan1
set arp-reply enable
arp-intf port12
end
```

### Creating a IPv6 Pool

1. Go to **Policy & Objects > IP Pools**.
2. Select **Create New**.
3. In the IP Pool Type field choose **IPv6 Pool**
4. Enter a name in the **Name** field for the new service
5. Include any description you would like in the **Comments** field
6. For the **External IP Range** fields, enter the lowest and highest addresses in the range.

### IPv6 Example for GUI

In this example, there is a similar situation to the One-to-one example earlier. There is a mail server that needs to be resolved to a specific IP address in Reverse DNS look-ups. The difference in this case is the company is an early adopter of IPv6 connectivity to the Internet.

Field	Value
IP Pool Type	IPv6 Pool
Name	Mail-svr-ipv6
Comments	Registered IPv6 address for mail server
External IP Range	fd2f:50ec:cdea:0663::1025 - fd2f:50ec:cdea:0663::1025

### Port Block Allocation Example for CLI

```
config firewall ippool6
edit Mail-svr-ipv6
set comments "Registered IPv6 address for mail server"
set startip fd2f:50ec:cdea:663::102
set endip fd2f:50ec:cdea:663::1025
end
```

## Services

While there are a number of services already configured within FortiOS, the firmware allows for administrators to configure their own. The reasons for doing this usually fall into one or more of the following categories:

- The service is not common enough to have a standard configuration
- The service is not established enough to have a standard configuration
- The service has a standard port number but there is a reason to use a different one:
  - Port is already in use by another service
  - For security reasons, want to avoid standard port

When looking at the list of preconfigured services it may seem like there are a lot, but keep in mind that the theoretical limit for port numbers is 65,535. This gives a fairly good sized range when you are choosing what port to assign a service but there are a few points to keep in mind.

- Most of the well known ports are in the range 0 - 1023
- Most ports assigned by the Internet Corporation for Assigned Names and Numbers (ICANN) will be in the 1024 - 49151 range
- Port numbers between 49,152 and 65,535 are often used for dynamic, private or ephemeral ports.

There are 3 Service objects that can be added and configured:

- Categories
- Services
- Service Groups

### Categories

In order to make sorting through the services easier, there is a field to categorize the services. Because selecting a category is part of the process for creating a new service, the configuration of categories will be explained first.

The services can be sorted into the following groups:

- General
- Web Access
- File Access
- Email
- Network Services
- Authentication
- Remote Access
- Tunneling
- VoIP, Messaging and Other Applications

- Web Proxy
- Uncategorized

The categories are for organization purposes so there is not many settings when creating a new one.

### Creating a new Service Category

1. Go to **Policy & Objects > Services**.
2. Select **Create New**. A drop down menu is displayed. Select **Category**
3. Input a **Name** for the category.
4. Input any additional information in the **Comments** field.
5. Press **OK**.

### Example

You plan on adding a number of devices such as web cameras that will allow the monitoring of the physical security of your datacenter. A number of non-standard services will have to be created and you would like to keep them grouped together under the heading of "Surveillance"

### Example of a New Category in the GUI

1. Go to **Policy & Objects > Objects > Services** and select **Create New > Category**.
2. Fill out the fields with the following information

Field	Value
Name	Surveillance
Comments	For DataCenter Surveillance Devices

3. Select **OK**.

### Example of a New Category in the CLI

Enter the following CLI command:

```
config firewall service category
edit Surveillance
set comment "For DataCenter Surveillance Devices"
end
```

### To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects > Services**. Select the Category Settings icon . A listing of the categories should be displayed.
2. Enter the following CLI command:

```
config firewall service category
show
```

This should bring up all of the categories. Check to see that the new one is displayed.

## Configuring a new service

Occasionally, the preconfigured list of services will not contain the needed service. There are a few variations in the creation of a service depending upon the protocol type, but the first steps in the creation of the service are common to all the variations.

To create a new service:

1. Go to **Policy & Objects > Services**.
2. Select **Create New**. A drop down menu is displayed. Select **Service**
3. Enter a name in the **Name** field for the new service
4. Include any description you would like in the **Comments** field
5. In the **Service Type** field choose between **Firewall** and **Explicit Proxy**.
6. Enable the toggle in the **Show in Service List**. If you can't see the service when you need to select it, it serves very little purpose.
7. For the **Category** field, choose the appropriate category from the **Category** drop down menu. If none is chosen, the **Uncategorized** option will be chosen by default.

## Protocol Options

This is the section where the configuration options of the service will differ depending on the type of protocol chosen. (The Step numbers will all continue on from the common step sequence).

The protocol options for **Firewall** service type are:

- **TCP/UDP/SCTP**
- **ICMP**
- **ICMP6**
- **IP**

The protocol options for **Proxy** service type are:

- **ALL**
- **CONNECT**
- **FTP**
- **HTTP**
- **SOCKS-TCP**
- **SOCKS-UDP**

## TCP/UDP/SCTP

8. For the **Protocol Type** field, choose **TCP/UDP/SCTP** from the drop down menu
9. For the **Address** field, choose IP Range or **FQDN** (Fully Qualified Domain Name) if there is to be a specific destination for the service. Depending on which type of address is selected, the field value needs to be filled with a FQDN string or an IP address in one of the 3 standard IPv4 address formats:
  - x.x.x.x - for a specific address
  - x.x.x.x/x - for a subnet
  - x.x.x.x-x.x.x.x - for a range of specific addresses
10. Configure the **Destination Port** by:

- Select from the drop down menu, **TCP**, **UDP** or **SCTP**
  - Enter the low end to the port range in the field indicated by grayed out **Low**.
  - Enter the high end of the port range in the field indicated by grayed out **High**. If there is only a single port in the range **High** can be left empty
  - Multiple ports or port ranges can be added by using the "+" at the beginning of the row
  - Rows can be removed by using the trash can symbol at the end of the row
11. If required, you can **Specify Source Ports** for the service by enabling the toggle switch.
    - The **Src Port** will match up with a **Destination Port**
    - **Src Ports** cannot be configured without there being a value for the **Destination Port**
    - The same rules for configuring the **Destination Ports** applies to the **Src Ports**
  12. Select **OK** to confirm the configuration

### Example

Example settings for a TCP protocol service. In this case, it is for an administrative connection to web servers on the DMZ. The protocol used is HTTPS which would normally use port 443, but that is already in use by another service such as Admin access to the firewall or an SSL-VPN connection.

Field	Value
Name	Example.com_WebAdmin
Comments	Admin connection to Example.com Website
Service Type	Firewall
Show in Service List	enabled
Category	Web Access
Protocol Options	
Protocol Type	TCP/UDP/SCTP
IP/FQDN	<left blank>
Destination Port	<ul style="list-style-type: none"> <li>• Protocol: TCP</li> <li>• Low: 4300</li> <li>• High: &lt;left blank&gt;</li> </ul>
Specify Source Ports	<disabled>

### Creating a new TCP/UDP/SCTP service in the CLI

The following is the creation of the same service using the command line.

```
config firewall service custom
edit Example.com_WebAdmin
set comment "Admin connection to Example.com Website"
```

```

        set category Web Access
        set protocol TCP/UDP/SCTP
        set tcp-portrange 4300
    end
end

```

## ICMP / ICMP6

8. For the **Protocol Type** field, choose **ICMP** or **ICMP6** from the drop down menu
9. In the **Type** field enter the appropriate type number based on the information found in ["ICMP Types and Codes" on page 1](#) or in ["ICMPv6 Types and Codes" on page 1](#), depending on whether the **Protocol Type** is **ICMP** or **ICMPv6**
10. In the **Code** field enter the appropriate code number for the type, if applicable, based on the information found in ["ICMP Types and Codes" on page 1](#) or in ["ICMPv6 Types and Codes" on page 1](#), depending on whether the **Protocol Type** is **ICMP** or **ICMPv6**
11. Select **OK** to confirm the configuration

### Example

Example settings for an ICMP.service. In this case it has been set up for some special testing of ICMP packets.

Field	Value
Name	ICMP test #4
Comments	For testing of proprietary network scanner
Service Type	Firewall
Show in Service List	enabled
Category	Network Services
Protocol Options	
Protocol Type	ICMP
Type	7
Code	<left blank>

### Creating a new ICMP service in the CLI

The following is the creation of the same service using the command line.

```

config firewall service custom
edit ICMP test4
    set comment "For testing of proprietary network scanner"
    set category Network Services
    set protocol ICMP
    set icmptype 7
end

```

end

## IP

8. For the **Protocol Type** field, choose **IP** from the drop down menu
9. In the **Protocol Number** field enter the numeric value based on the information found in ["Protocol Number" on page 1](#)
10. Select **OK** to confirm the configuration

## Example

Example settings for an IP.service. In this case it has been set up to communicate via an old protocol called QNX

Field	Value
Name	QNX
Comments	For QNX communications to the Development Lab
Service Type	Firewall
Show in Service List	enabled
Category	Uncategorized
Protocol Options	
Protocol Type	IP
Protocol Number	106

## Creating a new ICMP service in the CLI

The following is the creation of the same service using the command line.

```
config firewall service custom
edit ICMP test4
    set comment "For QNX communications to the Development Lab "
    set protocol IP
    set icmptype 106
end
end
```

In the CLI examples, the fields for **Show in Service List**, **Service Type** and in the example for IP, **Category** were not set because the values that they would have been set to were the default values and were already correctly set.

## ALL/CONNECT/FTP/HTTP/SOCKS-TCP/SOCKS-UDP

These options are available only if the **Service Type** is set to **Explicit Proxy**.

8. For the **Protocol Type** field, choose one of the following from the drop down menu:

- **ALL**
  - **CONNECT**
  - **FTP**
  - **HTTP**
  - **SOCKS-TCP**
  - **SOCKS-UDP**
9. For the **Address** field, choose IP Range or **FQDN** (Fully Qualified Domain Name) if there is to be a specific destination for the service. Depending on which type of address is selected, the field value needs to be filled with a FQDN string or an IP address in one of the 3 standard IPv4 address formats:
    - x.x.x.x - for a specific address
    - x.x.x.x/x - for a subnet
    - x.x.x.x-x.x.x.x - for a range of specific addresses
  10. Configure the **Destination Port** by:
    - Enter the low end to the TCP port range in the field indicated by grayed out **Low**.
    - Enter the high end of the TCP port range in the field indicated by grayed out **High**. If there is only a single port in the range **High** can be left empty
    - Multiple ports or port ranges can be added by using the "+" at the beginning of the row
    - Rows can be removed by using the trash can symbol at the end of the row
  11. If required, you can **Specify Source Ports** for the service by enabling the toggle switch.
    - The **Src Port** will match up with a **Destination Port**
    - **Src Ports** cannot be configured without there being a value for the **Destination Port**
    - The same rules for configuring the **Destination Ports** applies to the **Src Ports**
  12. Select **OK** to confirm the configuration

## Specific Addresses in TCP/UDP/SCTP

In the TCP/UDP/SCTP services it is also possible to set the parameter for a specific IP or Fully Qualified Domain Name address. The IP/FQDN field refers to the destination address of the traffic, not the source. This means for example, that you can set up a custom service that will describe in a policy the TCP traffic over port 80 going to the web site example.com, but you cannot set up a service that describes the TCP traffic over port 80 that is coming from the computer with the address 192.168.29.59.

## Service Groups

Just like some of the other firewall components, services can also be bundled into groups for ease of administration.

### Creating a ServiceGroup

1. Go to **Policy & Objects > Services**.
2. Select **Create New**. A drop down menu is displayed. Select **Service Group**
3. Input a **Group Name** to describe the services being grouped

4. Input any additional information in the **Comments** field.
5. Choose a **Type** of group. The options are **Firewall** or **Explicit Proxy**.
6. Add to the list of **Members** from the drop down menu. Using the + sign beside the field will allow the addition of multiple services.
7. Press **OK**.

### Example

Example of a New Service Group:

Field	Value
Group Name	Authentication Services
Comments	Services used in Authentication
Type	Firewall
Members	<ul style="list-style-type: none"><li>• Kerberos</li><li>• LDAP</li><li>• LDAP_UDP</li><li>• RADIUS</li></ul>

## Firewall schedules

Firewall schedules control when policies are in effect. When you add a security policy on a FortiGate unit you need to set a schedule to determine the time frame in which that the policy will be functioning. While it is not set by default, the normal schedule would be always. This would mean that the policy that has been created is always function and always policing the traffic going through the FortiGate. The time component of the schedule is based on a 24 hour clock notation or military time as some people would say.

There are two types of schedules: One-time schedules and recurring schedules.

### One-time schedule object

**One-Time** schedules are in effect only once for the period of time specified in the schedule. This can be useful for testing to limit how long a policy will be in effect in case it is not removed, or it can be used for isolated events such as a conference where you will only need a temporary infrastructure change for a few days.

The time frame for a One-time schedule is configured by using a start time which includes, Year | Month | Day | Hour | Minute and a Stop time which includes the same variables. So while the frequency of the schedule is only once it can last anywhere from 1 minute to multiple years.

### Configuring a One-time schedule object in the GUI

1. Go to **Policy & Objects > Schedules**.
2. Select **Create New**. A drop down menu is displayed. Select **Schedule**.
3. From the **Type** options, choose **One-time**.
4. Input a **Name** for the schedule object.

5. If you wish to add a **Color** to the icon in the GUI, you can click on the **Change** link to choose 1 of 32 color options.
6. Choose a **Start Date**.  
Selecting the field with the mouse will bring up an interactive calendar graphic that will allow the user to select the date. The date can also be typed in using the format YYYY/MM/DD.
7. Choose a **Start Time**.  
The **Start Time** is composed of two fields, **Hour** and **Minute**. Think of setting the time for a digital clock in 24 hour mode. The **Hour** value can be an integer from 0 and 23. The **Minute** value can be from 0 to 59. 0 and 0 would be midnight at the start of the day and 23 and 59 would be one minute to midnight at the end of the day. The value can be entered by keyboard or by using the up and down arrows in the field to select the value.
6. Choose an **End Date**.  
Configuration is the same as **Start Date**.
8. Choose a **Stop Time**.  
Configuration is the same as **Start Time**.
9. Enable/Disable **Pre-expiration event log**.  
This configures the system to create an event log 1 to 100 days before the **End Date** as a warning in case the schedule needs to be extended.
10. If the **Pre-expiration event log** is enabled, set the value for **Number of days before**.
11. Press **OK**.

### Example: Firewall Schedule - One-time

The company wants to change over their web site image to reference the new year. They have decided to take this opportunity to do some hardware upgrades as well. Their web site is business oriented so they have determined that over New Year's Eve there will be very limited traffic.

- They are going to need a maintenance window of 2 hours bracketing midnight on New Year's Eve.

### Configuration in the GUI

1. Go to **Policy & Objects > Objects > Schedule**.
2. Select **Create New > Schedule**.
3. Fill out the fields with the following information:

<b>Type</b>	One-time
<b>Name</b>	NewYearsEve_Maintenance
<b>Start Date</b>	2014/12/31 <use the built in calendar>
<b>End Date</b>	2015/01/01 <use the built in calendar>
<b>Start Time</b>	Hour: 23, Minute: 0
<b>Stop Time</b>	Hour: 1Minute: 0
<b>Pre-expiration event log</b>	<disable>

4. Select **OK**.

**To verify that the schedule was added correctly:**

1. Go to **Policy & Objects > Objects > Schedule**.
2. Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.

### Configuration in the CLI

1. Enter the following CLI command:

```
config firewall schedule onetime
edit maintenance_window
set start 23:00 2012/12/31
set end 01:00 2013/01/01
next
end
```

**To verify that the schedule was added correctly:**

1. Enter the following CLI command:

```
config firewall schedule onetime
edit <the name of the schedule you wish to verify>
show full-configuration
```

### Recurring schedule object

**Recurring** schedules are in effect repeatedly at specified times of specified days of the week. The Recurring schedule is based on a repeating cycle of the days of the week as opposed to every x days or days of the month. This means that you can configure the schedule to be in effect on Tuesday, Thursday, and Saturday but not every 2 days or on odd numbered days of the month.

If a recurring schedule has a stop time that is earlier than the start time, the schedule will take effect at the start time but end at the stop time on the next day. You can use this technique to create recurring schedules that run from one day to the next.

### Configuring a Recurring schedule object in the GUI

1. Go to **Policy & Objects > Schedules**.
2. Select **Create New**. A drop down menu is displayed. Select **Schedule**.
3. From the **Type** options, choose **Recurring**.
4. Input a **Name** for the schedule object.
5. If you wish to add a **Color** to the icon in the GUI, you can click on the **Change** link to choose 1 of 32 color options.
6. From the **Days** options, choose the day of the week that you would like this schedule to apply to. The schedule will be in effect on the days of the week that have a check mark in the checkbox to the left of the name of the weekday.
7. If the scheduled time is the whole day, leave the **All Day** toggle switch enabled. If the schedule is for specific times during the day, disable the **All Day** toggle switch.
8. If the All Day option is disabled, choose a **Start Time**.

The **Start Time** is composed of two fields, **Hour** and **Minute**. Think of setting the time for a digital clock in 24 hour mode. The **Hour** value can be an integer from 0 and 23. The **Minute** value can be from 0 to 59. 0 and 0 would be midnight at the start of the day and 23 and 59 would be one minute to midnight at the end of the day. The value can be entered by keyboard or by using the up and down arrows in the field to select the value.

7. Choose a **Stop Time**.

Configuration is the same as **Start Time**.

8. Press **OK**.

Because recurring schedules do not work with DENY policies, the strategy when designing a schedule should *not* be to determine when users cannot access a policy but to build the schedules around when it *is* possible to access the policy.

### Example: Firewall Schedule - Recurring

The Company wants to allow the use of Facebook by employees, but only during none business hours and the lunch break.

- The business hours are 9:00 p.m. to 6:00 p.m.
- The Lunch break is 12:00 p.m. to 1:00 p.m.
- The plan is to create a schedule to cover the morning business hours and the afternoon business hours and block access to the Facebook web site during that time.

### Configuration in the GUI

1. Go to **Policy & Objects > Objects > Schedule**.
2. Select **Create New > Schedule**.
3. Fill out the fields with the following information:

<b>Type</b>	Recurring
<b>Name</b>	Morning_Business_Hours
<b>Days</b>	Monday, Tuesday, Wednesday, Thursday, Friday
<b>Start Time</b>	Hour = 9, Minute = 0
<b>Stop Time</b>	Hour = 12, Minute = 0

4. Select **OK**.

5. Create a second new schedule.

<b>Type</b>	Recurring
<b>Name</b>	Morning_Business_Hours
<b>Days</b>	Monday, Tuesday, Wednesday, Thursday, Friday

<b>Start Time</b>	Hour = 13, Minute = 0
<b>Stop Time</b>	Hour = 18, Minute = 0

6. Select **OK**.

#### To verify that the schedule was added correctly:

1. Go to **Policy & Objects > Objects > Schedule**.
2. Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.

#### Configuration in the CLI

1. Enter the following CLI command:

```
config firewall schedule recurring
edit Morning_Business_Hours
set day monday tuesday wednesday thursday friday
set start 09:00
set end 12:00
end
```

2. Enter the following CLI command:

```
config firewall schedule recurring
edit Afternoon_Business_Hours
set day monday tuesday wednesday thursday friday
set start 13:00
set end 18:00
end
```

#### To verify that the schedule was added correctly:

1. Enter the following CLI command:

```
config firewall schedule recurring
edit <the name of the schedule you wish to verify>
show full-configuration
```

### Schedule Groups

You can organize multiple firewall schedules into a schedule group to simplify your security policy list. The schedule parameter in the policy configuration does not allow for the entering of multiple schedules into a single policy so if you have a combination of time frames that you want to schedule the policy for then the best approach, rather than making multiple policies is to use a schedule group.

#### Creating a Schedule Group object

1. Go to **Policy & Objects > Schedules**.
2. Select **Create New**. A drop down menu is displayed. Select **Schedule Group**.
3. Input a **Name** for the schedule object.
4. In the **Members** field, select the "+" to bring forth the panel for selecting entries.
5. Press **OK**.

## Example

Your Internet policy allows employees to visit Social Media sites from company computers but not during what is considered working hours. The offices are open a few hours before working hours and the doors are not locked until a few hours after official closing so work hours are from 9 to 5 with a lunch break from Noon to 1:00 p.m.

Your approach is to block the traffic between 9 and noon and between 1:00 p.m. and 5:00 p.m. This means you will need two schedules for a single policy and the schedule group handles this for you. Schedule groups can contain both recurring and one-time schedules. Schedule groups cannot contain other schedule groups.

## Schedule expiration

The schedule in a security policy enables certain aspects of network traffic to occur for a specific length of time. What it does not do however, is police that time. That is, the policy is active for a given time frame, and as long as the session is open, traffic can continue to flow.

For example, in an office environment, Skype use is allowed between noon and 1pm. During that hour, any Skype traffic continues. As long as that session is open, after the 1pm end time, the Skype conversations can continue, yet new sessions will be blocked. Ideally, the Skype session should close at 1pm.

Using a CLI command you can set the schedule to terminate all sessions when the end time of the schedule is reached. Within the config firewall command enter the command:

```
set schedule-timeout enable
```

By default, this option is set to disable.

A few further settings are needed to make this work.

```
config firewall policy
  edit ID
    set firewall-session-dirty check-new
  end

config system settings
  set firewall-session-dirty check-policy-option
end
```

The Policy window will indicate when a policy has become invalid due to its schedule parameters referring only to times in the past.

## Firewall-session-dirty setting

The firewall-session-dirty setting has three options

check-all	CPU flushes all current sessions and re-evaluates them. [default]
check-new	CPU keeps existing sessions and applies policy changes to new sessions only. This reduces CPU load and the possibility of packet loss.
check-policy-option	Use the option selected in the firewall-session-dirty field of the firewall policy (check-all or check-new, as above, but per policy).

## Secure Web Gateway, WAN Optimization, Web Caching and WCCP

You can use FortiGate WAN optimization and web caching to improve performance and security of traffic passing between locations on your wide area network (WAN) or from the Internet to your web servers. You can also use the FortiGate unit as an explicit FTP and web proxy server. If your FortiGate unit supports web caching, you can also add web caching to any HTTP sessions including WAN optimization, explicit web proxy and other HTTP sessions.

the next sections of this document describes how FortiGate WAN optimization, web caching, explicit web proxy, explicit FTP proxy and WCCP work and also describes how to configure these features.

### Before you begin

Before you begin to configure WAN optimization, Web caching, explicit proxies or WCCP, take a moment to note the following:

### FortiGate models that support WAN optimization

WAN optimization is available on FortiGate models with internal storage that also support SSL acceleration. Internal storage includes high-capacity internal hard disks, AMC hard disk modules, FortiGate Storage Modules (FSMs) or over 4 Gbytes of internal flash storage. All of these storage locations can provide similar web caching and byte caching performance. If you add more than one storage location (for example, by creating multiple partitions on a storage device, by using more than one FSM, or by using an FSM and AMC hard disk in the same FortiGate unit) you can configure different storage locations for web caching and byte caching.

### Distributing WAN optimization, explicit proxy, and web caching to multiple CPU Cores

By default WAN optimization, explicit proxy and web caching is handled by half of the CPU cores in a FortiGate unit. For example, if your FortiGate unit has 4 CPU cores, by default two will be used for WAN optimization, explicit proxy and web caching. You can use the following command to change the number of CPU cores that are used.

```
config system global
    set wad-worker-count <number>
end
```

The value for <number> can be between 1 and the total number of CPU cores in your FortiGate unit. Adding more cores may enhance WAN optimization, explicit proxy and web caching performance and reduce the performance of other FortiGate systems.

### Toggling Disk Usage for logging or wan-opt

Both logging and WAN Optimization use hard disk space to save data. In FortiOS, you cannot use the same hard disk for WAN Optimization and logging.

- If the FortiGate has one hard disk, then it can be used for either disk logging or WAN optimization, but not both. By default, the hard disk is used for disk logging.
- If the FortiGate has two hard disks, then one disk is always used for disk logging and the other disk is always used for WAN optimization.

On the FortiGate, go to **System > Advanced > Disk Settings** to switch between **Local Log** and **WAN Optimization**.

You can also change disk usage from the CLI using the following command:

```
configure system global
  set disk-usage {log | wanopt}
end
```

The Toggle Disk Usage feature is supported on all new "E" Series models, while support for "D" Series models may vary.

Please refer to the [Feature Platform Matrix](#) for more information.

Changing the disk setting formats the disk, erases current data stored on the disk and disables either disk logging or WAN Optimization.

You can configure WAN Optimization from the CLI or the GUI. To configure WAN Optimization from the GUI you must go to **System > Feature Visibility** and turn on WAN Optimization.

Remote logging (including logging to FortiAnalyzer and remote Syslog servers) is not affected by using the single local hard disk for WAN Optimization.

### Enabling WAN Optimization affects more than just disk logging

In addition to affecting WAN Optimization, the following table shows other features affected by the FortiGate disk configuration.

#### Features affected by Disk Usage as per the number of internal hard disks on the FortiGate

Feature	Logging Only (1 hard disk)	WAN Opt. Only (1 hard disk)	Logging & WAN Opt. (2 hard disks)
<b>Logging</b>	Supported	Not supported	Supported
<b>Report/Historical FortiView</b>	Supported	Not supported	Supported
<b>Firewall Packet Capture (Policy Capture and Interface Capture)</b>	Supported	Not supported	Supported
<b>AV Quarantine</b>	Supported	Not supported	Supported

Feature	Logging Only (1 hard disk)	WAN Opt. Only (1 hard disk)	Logging & WAN Opt. (2 hard disks)
<b>IPS Packet Capture</b>	Supported.	Not supported	Supported
<b>DLP Archive</b>	Supported	Not supported	Supported
<b>Sandbox DB &amp; Results</b>	FortiSandbox database and results are also stored on disk, but will not be affected by this feature.		

## Example topologies relevant to WAN Optimization

FortiGate WAN optimization consists of a number of techniques that you can apply to improve the efficiency of communication across your WAN. These techniques include protocol optimization, byte caching, web caching, SSL offloading, and secure tunneling. Protocol optimization can improve the efficiency of traffic that uses the CIFS, FTP, HTTP, or MAPI protocol, as well as general TCP traffic. Byte caching caches files and other data on FortiGate units to reduce the amount of data transmitted across the WAN. Web caching stores web pages on FortiGate units to reduce latency and delays between the WAN and web servers. SSL offloading offloads SSL decryption and encryption from web servers onto FortiGate SSL acceleration hardware. Secure tunneling secures traffic as it crosses the WAN.

You can apply different combinations of these WAN optimization techniques to a single traffic stream depending on the traffic type. For example, you can apply byte caching and secure tunneling to any TCP traffic. For HTTP and HTTPS traffic, you can also apply protocol optimization and web caching.

You can configure a FortiGate unit to be an explicit web proxy server for both IPv4 and IPv6 traffic and an explicit FTP proxy server. Users on your internal network can browse the Internet through the explicit web proxy server or connect to FTP servers through the explicit FTP proxy server. You can also configure these proxies to protect access to web or FTP servers behind the FortiGate unit using a reverse proxy configuration.

Web caching can be applied to any HTTP or HTTPS traffic, this includes normal traffic accepted by a security policy, explicit web proxy traffic, and WAN optimization traffic.

You can also configure a FortiGate unit to operate as a Web Cache Communication Protocol (WCCP) client or server. WCCP provides the ability to offload web caching to one or more redundant web caching servers.

FortiGate units can also apply security profiles to traffic as part of a WAN optimization, explicit web proxy, explicit FTP proxy, web cache and WCCP configuration. Security policies that include any of these options can also include settings to apply all forms of security profiles supported by your FortiGate unit.

## Basic WAN optimization topology

The basic FortiGate WAN optimization topology consists of two FortiGate units operating as WAN optimization peers intercepting and optimizing traffic crossing the WAN between the private networks.

### Security device and WAN optimization topology

FortiGate units can be deployed as security devices that protect private networks connected to the WAN and also perform WAN optimization. In this configuration, the FortiGate units are configured as typical security devices for the private networks and are also configured for WAN optimization. The WAN optimization configuration intercepts traffic to be optimized as it passes through the FortiGate unit and uses a WAN optimization tunnel with another FortiGate unit to optimize the traffic that crosses the WAN.

You can also deploy WAN optimization on single-purpose FortiGate units that only perform WAN optimization. In the out of path WAN optimization topology shown below, FortiGate units are located on the WAN outside of the private networks. You can also install the WAN optimization FortiGate units behind the security devices on the private networks.

The WAN optimization configuration is the same for FortiGate units deployed as security devices and for single-purpose WAN optimization FortiGate units. The only differences would result from the different network topologies.

### Out-of-path WAN Optimization topology

In an out-of-path topology, one or both of the FortiGate units configured for WAN optimization are not directly in the main data path. Instead, the out-of-path FortiGate unit is connected to a device on the data path, and the device is configured to redirect sessions to be optimized to the out-of-path FortiGate unit.

#### Single-purpose WAN optimization topology

The following out-of-path FortiGate units are configured for WAN optimization and connected directly to FortiGate units in the data path. The FortiGate units in the data path use a method such as policy routing to redirect traffic to be optimized to the out-of-path FortiGate units. The out-of-path FortiGate units establish a WAN optimization tunnel between each other and optimize the redirected traffic.

### Out-of-path WAN optimization

One of the benefits of out-of-path WAN optimization is that out-of-path FortiGate units only perform WAN optimization and do not have to process other traffic. An in-path FortiGate unit configured for WAN optimization also has to process other non-optimized traffic on the data path.

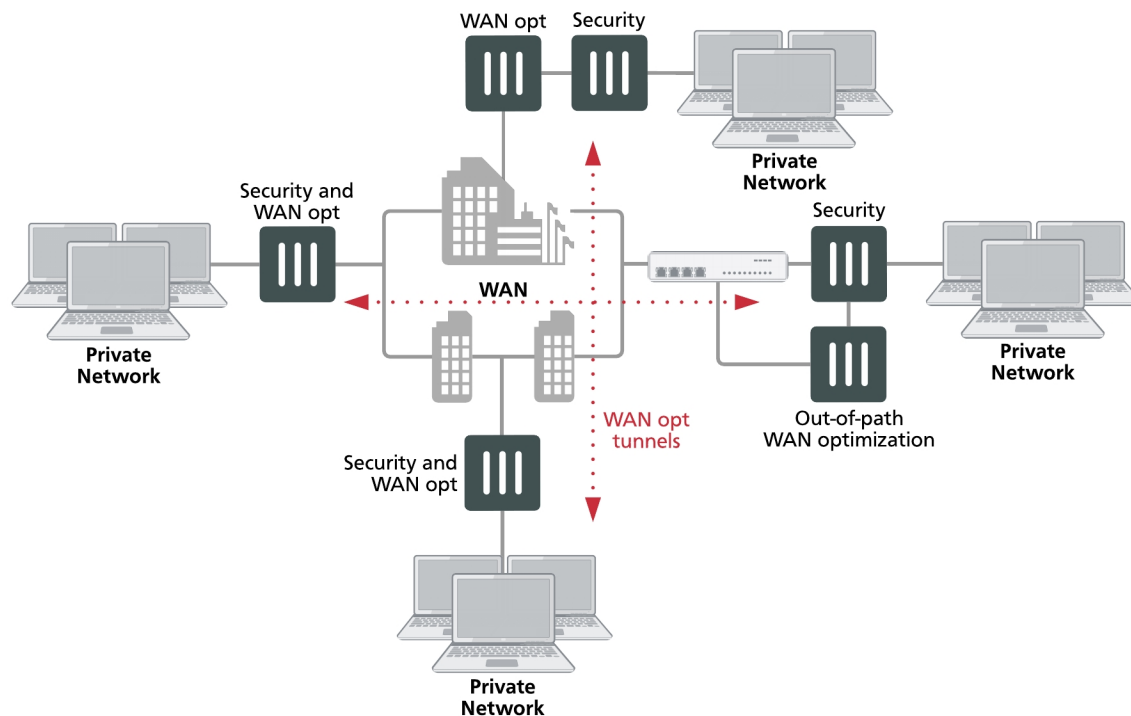

The out-of-path FortiGate units can operate in NAT/Route or Transparent mode.

Other out-of-path topologies are also possible. For example, you can install the out-of-path FortiGate units on the private networks instead of on the WAN. Also, the out-of-path FortiGate units can have one connection to the network instead of two. In a one-arm configuration such as this, security policies and routing have to be configured to send the WAN optimization tunnel out the same interface as the one that received the traffic.

### Topology for multiple networks

As shown in below, you can create multiple WAN optimization configurations between many private networks. Whenever WAN optimization occurs, it is always between two FortiGate units, but you can configure any FortiGate unit to perform WAN optimization with any of the other FortiGate units that are part of your WAN.

### WAN optimization among multiple networks

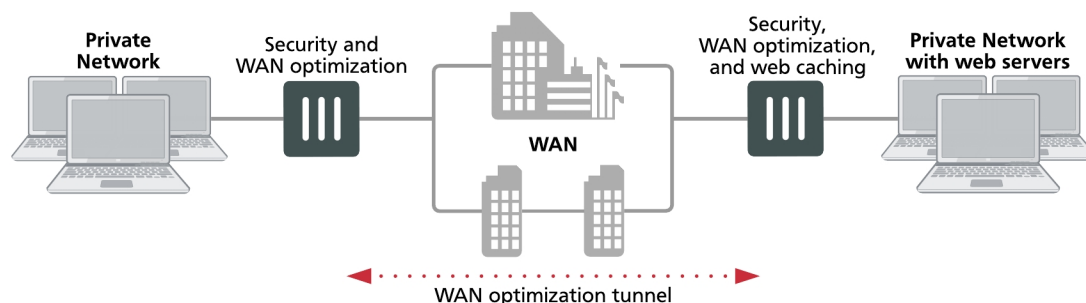

You can also configure WAN optimization between FortiGate units with different roles on the WAN. FortiGate units configured as security devices and for WAN optimization can perform WAN optimization as if they are single-purpose FortiGate units just configured for WAN optimization.

### WAN optimization with web caching

You can add web caching to a WAN optimization topology when users on a private network communicate with web servers located across the WAN on another private network.

#### WAN optimization with web caching topology

The topology above is the same as that shown in [WAN optimization with web caching on page 962](#) with the addition of web caching to the FortiGate unit in front of the private network that includes the web servers. You can also add web caching to the FortiGate unit that is protecting the private network. In a similar way, you can add web caching to any WAN Optimization topology.

## Explicit Web proxy topologies

You can configure a FortiGate unit to be an explicit web proxy server for Internet web browsing of IPv4 and IPv6 web traffic. To use the explicit web proxy, users must add the IP address of the FortiGate interface configured for the explicit web proxy to their web browser proxy configuration.

### Explicit web proxy topology

If the FortiGate unit supports web caching, you can also add web caching to the security policy that accepts explicit web proxy sessions. The FortiGate unit then caches Internet web pages on a hard disk to improve web browsing performance.

### Explicit web proxy with web caching topology

## Explicit FTP proxy topologies

You can configure a FortiGate unit to be an explicit FTP proxy server for FTP users. To use the explicit web proxy, FTP users must connect to and authenticate with the explicit FTP proxy before connecting to an FTP server.

### Explicit FTP proxy topology

You can also configure reverse explicit FTP proxy. In this configuration, users on the Internet connect to the explicit web proxy before connecting to an FTP server installed behind a FortiGate unit.

### Reverse explicit FTP proxy topology

## Web caching topologies

FortiGate web caching can be added to any security policy and any HTTP or HTTPS traffic accepted by that security policy can be cached on the FortiGate unit hard disk. This includes WAN optimization and explicit web proxy traffic. The network topologies for these scenarios are very similar. They involved a FortiGate unit installed between users and web servers with web caching enabled.

A typical web-caching topology includes one FortiGate unit that acts as a web cache server. Web caching is enabled in a security policy and the FortiGate unit intercepts web page requests accepted by the security policy, requests web pages from the web servers, caches the web page contents, and returns the web page contents to the users. When the FortiGate unit intercepts subsequent requests for cached web pages, the FortiGate unit contacts the destination web server just to check for changes.

### Web caching topology

You can also configure reverse proxy web-caching. In this configuration, users on the Internet browse to a web server installed behind a FortiGate unit. The FortiGate unit intercepts the web traffic (HTTP and HTTPS) and caches pages from the web server. Reverse proxy web caching on the FortiGate unit reduces the number of requests that the web server must handle, leaving it free to process new requests that it has not serviced before.

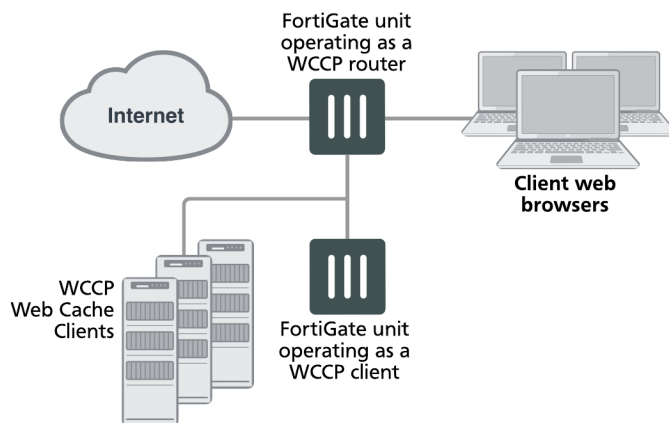

### Reverse proxy web caching topology

## WCCP topologies

You can operate a FortiGate unit as a Web Cache Communication Protocol (WCCP) router or cache engine. As a router, the FortiGate unit intercepts web browsing requests from client web browsers and forwards them to a WCCP cache engine. The cache engine returns the required cached content to the client web browser. If the cache server does not have the required content it accesses the content, caches it and returns the content to the client web browser.

### WCCP topology

FortiGate units can also operate as WCCP cache servers, communicating with WCCP routers, caching web content and providing it to client web browsers as required.

WCCP is transparent to client web browsers. The web browsers do not have to be configured to use a web proxy.

## Inside FortiOS: WAN Optimization

Enterprises deploying FortiOS can leverage WAN optimization to provide fast and secure application responses between locations on a Wide Area Network (WAN). The web caching component of FortiOS WAN optimization extends this protection and performance boost to cloud services.

### Centralize without compromising your WAN performance

Many multi-location enterprise environments reduce costs and consolidate resources by centralizing applications or providing applications in the cloud. Efficient and high-speed communication between applications and their users is critical. Remote sites don't always have access to high bandwidth, but users at all sites expect consistent network performance. Minimizing user impact and improving performance is especially vital when applications designed for local area networks (LANs) are on the cloud.

Even applications that work fine on a local LAN, such as Windows File Sharing (CIFS), email exchange (MAPI), and many others, suffer from bandwidth limitations and latency issues when accessed over a WAN. This results in a loss of productivity and a perceived need for expensive network upgrades. FortiOS's WAN Optimization provides an inexpensive and easy way to deploy a solution to this problem.

FortiOS is commonly deployed in central offices, satellite offices, and in the cloud to provide secure communications across a WAN using IPsec or SSL VPN. This installed infrastructure can be leveraged to add more value by using WAN Optimization to accelerate WAN traffic and web caching to accelerate cloud services.

### FortiOS WAN Optimization

FortiOS includes license-free WAN Optimization on most current FortiGate devices. WAN Optimization is a comprehensive solution that maximizes your WAN performance and provides intelligent bandwidth management and unmatched consolidated security performance. WAN Optimization reduces your network overhead and removes unnecessary traffic for a better overall performance experience. Efficient use of bandwidth and better

application performance will remove the need for costly WAN link upgrades between data centers and other expensive solutions for your network traffic growth.

## Protocol optimization

Protocol optimization is effective for applications designed for the LAN that do not function well on low bandwidth high latency networks. FortiOS protocol optimization improves the efficiency of CIFS, FTP, HTTP, MAPI, and general TCP sessions.

**Regular bandwidth usage**

**Improved bandwidth usage with FortiGate protocol optimization**

For example, CIFS, which is a fairly “chatty” protocol, requires many background transactions to successfully transfer a single file. When transferring the file, CIFS sends small chunks of data and waits sequentially for each chunk’s arrival and acknowledgment before sending the next. This large amount of request/acknowledgement traffic can delay transfers. FortiOS CIFS WAN Optimization removes this chattiness and gets on with the job of transferring the file.

TCP protocol optimization uses techniques such as SACK support, window scaling and window size adjustment, and connection pooling to remove common WAN TCP bottlenecks.

## Web caching

In an enterprise environment, multiple users will often want to get the same content (for example, a sales spreadsheet, a corporate presentation or a PDF from a cloud service, or a software update). With FortiOS Web caching, content from the cloud, from the web or from other sites on the WAN is download once and cached on the local FortiGate device. When other users access the same content they download it from the cache. The result is less bandwidth use and reduced latency for the file requester.

FortiOS web caching also recognizes requests for Windows or MS-Office updates and downloads the new update file in the background. Once downloaded to the cache, the new update file is available to all users and all subsequent requests for this update are rapidly downloaded from the cache.

## Byte caching

Byte caching improves caching by accelerating the transfer of similar, but not identical content. Byte caching accelerates multiple downloads of different email messages with the same corporate disclaimer by downloading the disclaimer over the WAN once and then downloading all subsequent disclaimers from a local FortiGate unit. Byte caching reduces the amount of data crossing the WAN when multiple different emails with the same or similar attachments or different versions of an attachment are downloaded from a corporate email server to different locations over the WAN.

## Dynamic data chunking

Dynamic data chunking detects and optimizes persistent data chunks in changed files or in data embedded in traffic that uses an unknown protocol. For example, dynamic chunking can cache data in Lotus notes traffic and make the data chunks available for email and other protocols.

## Data Deduplication

Byte caching breaks large units of application data, like an email attachment or a file download, into manageable small chunks of data. Each chunk of data is labeled with a hash, and chunks with their respective hashes are stored in a database on the local FortiGate unit. When a remote user request a file, the WAN Optimization sends the hashes, rather than the actual data. The FortiGate unit at the other end of the WAN tunnel reassembles the data from its own hash database, only downloading chunks that it is missing. Deduplication, or the process of eliminating duplicate data, will reduce space consumption. In addition to reducing the amount of data downloaded across the WAN, byte caching is not application specific and assists by accelerating all of the protocols supported by WAN Optimization.

## Server Monitoring and Management

The health and performance of real servers can be monitored from the FortiGate GUI. Virtual servers and their assigned real servers can be monitored for health status, if there have been any monitor events, number of active sessions, round trip time and number of bytes processed. Should a server become problematic and require administration, it can be gracefully removed from the Real Server pool to enable disruption free maintenance. When a removed real server is able to operate it can gracefully be added back to the virtual server.

## SSL acceleration

SSL is used by many organizations to keep WAN communications private. WAN Optimization boosts SSL acceleration properties of FortiGate FortiASIC hardware by accelerating SSL traffic across the WAN. The FortiGate unit handles SSL encryption/decryption for corporate servers providing SSL encrypted connections over the WAN.

## VPN replacement

FortiOS WAN optimization supports secure SSL-encrypted tunnels between FortiGate units on the WAN. Employing secure WAN Optimization tunnels can replace IPsec VPNs between sites. The result is a single, relatively simple configuration that supports optimization and privacy of communication across the WAN and uses FortiGate SSL acceleration to provide high performance.

## Road warriors and home workers

The drive to give employees greater flexibility and reduce operational costs has led to more remote workers, both at home and on the road. Whether accessing the office from a hotel, public wireless hotspot, or home, the problem is the same: low bandwidth and high latency harming application performance. WAN Optimization is integrated into FortiClient, which can be installed on PCs and wireless devices to optimize communication between remote workers and their offices.

### Reduce your...

- **Capital outlay:** Organizations only need to purchase a single device per location.
- **Licensing costs:** WAN Optimization is included with FortiOS. Additional licenses are not needed.
- **Network complexity:** Small offices that may not have the space or power connections for multiple devices do not need to worry: no additional devices are required.

## WAN Optimization Concepts

### Client/server architecture

Traffic across a WAN typically consists of clients on a client network communicating across a WAN with a remote server network. The clients do this by starting communication sessions from the client network to the server network. These communication sessions can be open text over the WAN or they can be encrypted by SSL VPN or IPsec VPN.

To optimize these sessions, you can add **WAN optimization security policies** to the **client-side FortiGate unit** to accept sessions from the client network that are destined for the server network. The client-side FortiGate unit is located between the client network and the WAN. WAN optimization security policies include **WAN optimization profiles** that control how the traffic is optimized.

The client-side FortiGate unit must also include the IP address of the **server-side FortiGate unit** in its WAN optimization **peer** configuration. The server-side FortiGate unit is located between the server network and the WAN. The peer configuration allows the client-side FortiGate unit to find the server-side FortiGate unit and attempt to establish a WAN optimization **tunnel** with it.

For the server-side FortiGate unit you must add a security policy with **wanopt** as the **Incoming Interface**. This security policy allows the FortiGate unit to accept WAN optimization sessions from the client-side FortiGate unit. For the server-side FortiGate unit to accept a WAN optimization connection it must have the client-side FortiGate unit in its WAN optimization peer configuration.

WAN optimization profiles are only added to the client-side WAN optimization security policy. The server-side FortiGate unit employs the WAN optimization settings set in the WAN optimization profile on the client-side FortiGate unit.

---

### Client/server architecture

When both peers are identified the FortiGate units attempt to establish a WAN optimization **tunnel** between them. WAN optimization tunnels use port 7810. All optimized data flowing across the WAN between the client-side and server-side FortiGate units use this tunnel. WAN optimization tunnels can be encrypted using SSL encryption to keep the data in the tunnel secure.

Any traffic can be sent through a WAN optimization tunnel. This includes SSL and IPsec VPN traffic. However, instead of configuring SSL or IPsec VPN for this communication you can add SSL encryption using the WAN optimization tunnel.

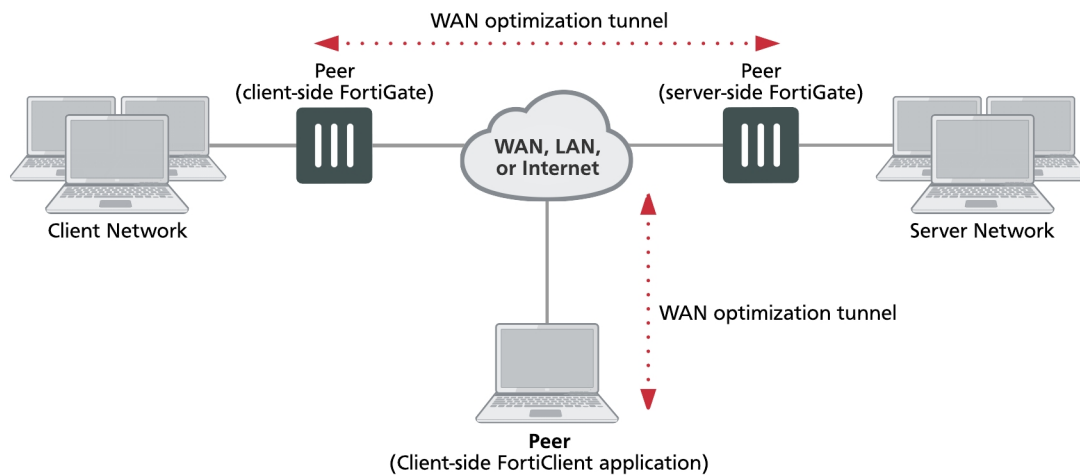

In addition to basic identification by peer host ID and IP address you can configure WAN optimization **authentication** using certificates and pre-shared keys to improve security. You can also configure FortiGate units involved in WAN optimization to accept connections from any identified peer or restrict connections to specific peers.

The FortiClient application can act in the same manner as a client-side FortiGate unit to optimize traffic between a computer running FortiClient and a FortiGate unit.

### WAN optimization peers

The client-side and server-side FortiGate units are called WAN optimization peers because all of the FortiGate units in a WAN optimization network have the same peer relationship with each other. The client and server roles just relate to how a session is started. Any FortiGate unit configured for WAN optimization can be a client-side and a server-side FortiGate unit at the same time, depending on the direction of the traffic. Client-side FortiGate units initiate WAN optimization sessions and server-side FortiGate units respond to the session requests. Any FortiGate unit can simultaneously be a client-side FortiGate unit for some sessions and a server-side FortiGate unit for others.

### WAN optimization peer and tunnel architecture

To identify all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with, you add host IDs and IP addresses of all of the peers to the FortiGate unit configuration. The peer IP address is actually the IP address of the peer unit interface that communicates with the FortiGate unit.

### Protocol optimization

Protocol optimization techniques optimize bandwidth use across the WAN. These techniques can improve the efficiency of communication across the WAN optimization tunnel by reducing the amount of traffic required by communication protocols. You can apply protocol optimization to Common Internet File System (CIFS), FTP, HTTP, MAPI, and general TCP sessions. You can apply general TCP optimization to MAPI sessions.

For example, CIFS provides file access, record locking, read/write privileges, change notification, server name resolution, request batching, and server authentication. CIFS is a fairly “chatty” protocol, requiring many background transactions to successfully transfer a single file. This is usually not a problem across a LAN. However, across a WAN, latency and bandwidth reduction can slow down CIFS performance.

When you select the CIFS protocol in a WAN optimization profile, the FortiGate units at both ends of the WAN optimization tunnel use a number of techniques to reduce the number of background transactions that occur over the WAN for CIFS traffic.

If a policy accepts a range of different types of traffic, you can set **Protocol** to **TCP** to apply general optimization techniques to TCP traffic. However, applying this TCP optimization is not as effective as applying more protocol-specific optimization to specific types of traffic. TCP protocol optimization uses techniques such as TCP SACK support, TCP window scaling and window size adjustment, and TCP connection pooling to remove TCP bottlenecks.

### Protocol optimization and MAPI

By default the MAPI service uses port number 135 for RPC port mapping and may use random ports for MAPI messages. The random ports are negotiated through sessions using port 135. The FortiOS DCE-RPC session helper learns these ports and opens pinholes for the messages. WAN optimization is also aware of these ports and attempts to apply protocol optimization to MAPI messages that use them. However, to configure protocol optimization for MAPI you should set the WAN optimization profile to a single port number (usually port 135). Specifying a range of ports may reduce performance.

## Byte caching

Byte caching breaks large units of application data (for example, a file being downloaded from a web page) into small chunks of data, labeling each chunk of data with a hash of the chunk and storing those chunks and their hashes in a database. The database is stored on a WAN optimization storage device. Then, instead of sending the actual data over the WAN tunnel, the FortiGate unit sends the hashes. The FortiGate unit at the other end of the tunnel receives the hashes and compares them with the hashes in its local byte caching database. If any hashes match, that data does not have to be transmitted over the WAN optimization tunnel. The data for any hashes that does not match is transferred over the tunnel and added to that byte caching database. Then the unit of application data (the file being downloaded) is reassembled and sent to its destination.

The stored byte caches are not application specific. Byte caches from a file in an email can be used to optimize downloading that same file or a similar file from a web page.

The result is less data transmitted over the WAN. Initially, byte caching may reduce performance until a large enough byte caching database is built up.

To enable byte caching, you select **Byte Caching** in a WAN optimization profile.

Byte caching cannot determine whether or not a file is compressed (for example a zip file), and caches compressed and non-compressed versions of the same file separately.

## Dynamic data chunking for byte caching

Dynamic data chunking can improve byte caching by improving detection of data chunks that are already cached in changed files or in data embedded in traffic using an unknown protocol. Dynamic data chunking is available for HTTP, CIFS and FTP.

Use the following command to enable dynamic data chunking for HTTP in the default WAN optimization profile.

```
config wanopt profile
  edit default
    config http
      set prefer-chunking dynamic
    end
```

By default dynamic data chunking is disabled and `prefer-chunking` is set to `fix`.

## WAN optimization transparent mode

WAN optimization is transparent to users. This means that with WAN optimization in place, clients connect to servers in the same way as they would without WAN optimization. However, servers receiving packets after WAN optimization “see” different source addresses depending on whether or not transparent mode is selected for WAN optimization. If transparent mode is selected, WAN optimization keeps the original source address of the packets, so servers appear to receive traffic directly from clients. Routing on the server network should be configured to route traffic with client source IP addresses from the server-side FortiGate unit to the server and back to the server-side FortiGate unit.

Some protocols, for example CIFS, may not function as expected if transparent mode is **not** selected. In most cases, for CIFS WAN optimization you should select transparent mode and make sure the server network can route traffic as described to support transparent mode.

If transparent mode is not selected, the source address of the packets received by servers is changed to the address of the server-side FortiGate unit interface that sends the packets to the servers. So servers appear to receive packets from the server-side FortiGate unit. Routing on the server network is simpler in this case because client addresses are not involved. All traffic appears to come from the server-side FortiGate unit and not from individual clients.

Do not confuse WAN optimization transparent mode with FortiGate transparent mode. WAN optimization transparent mode is similar to source NAT. FortiGate Transparent mode is a system setting that controls how the FortiGate unit (or a VDOM) processes traffic.

## Configuring Transparent mode

You can configure transparent mode by selecting **Transparent** in a WAN Optimization profile. The profile is added to an active WAN Optimization policy.

When you configure a passive WAN Optimization policy you can accept the active policy transparent setting or you can override the active policy transparent setting. From the GUI you can do this by setting the **Passive Option** as follows:

- **default** use the transparent setting in the WAN Optimization profile added to the active policy (client-side configuration).
- **transparent** impose transparent mode (override the active policy transparent mode setting). Packets exiting the FortiGate keep their original source addresses.
- **non-transparent** impose non-transparent mode (override the active policy transparent mode setting). Packets exiting the FortiGate have their source address changed to the address of the server-side FortiGate unit interface that sends the packets to the servers.

From the CLI you can use the following command:

```
config firewall policy
  set wanopt-passive-opt {default | transparent | non-transparent}
end
```

## FortiClient WAN optimization

PCs running the FortiClient application are client-side peers that initiate WAN optimization tunnels with server-side peer FortiGate units. However, you can have an ever-changing number of FortiClient peers with IP addresses that also change regularly. To avoid maintaining a list of such peers, you can instead configure WAN optimization to accept any peer and use authentication to identify FortiClient peers.

Together, the WAN optimization peers apply the WAN optimization features to optimize the traffic flow over the WAN between the clients and servers. WAN optimization reduces bandwidth requirements, increases throughput, reduces latency, offloads SSL encryption/decryption and improves privacy for traffic on the WAN.

For more details, see [FortiClient WAN optimization on page 1](#).

## Operating modes and VDOMs

To use WAN optimization, the FortiGate units can operate in either NAT/Route or Transparent mode. The client-side and server-side FortiGate units do not have to be operating in the same mode.

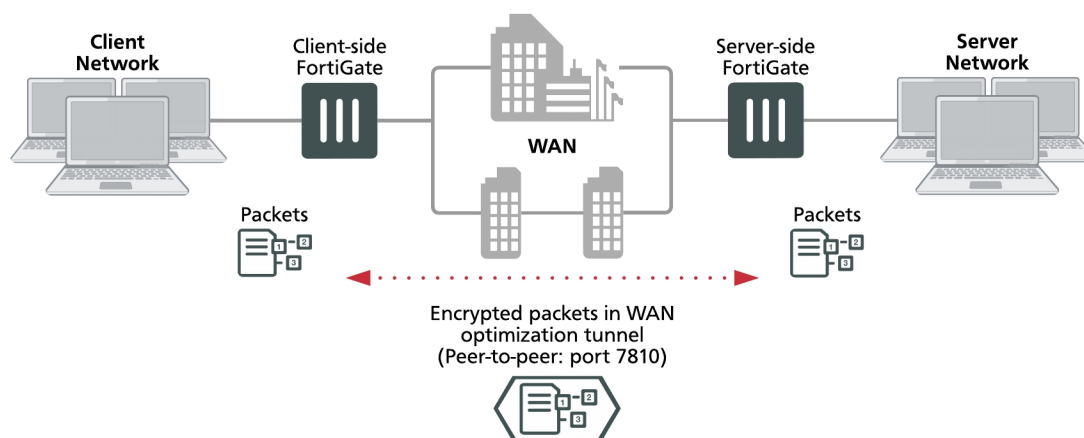

As well, the FortiGate units can be configured for multiple virtual domain (VDM) operation. You configure WAN optimization for each VDM and configure one or both of the units to operate with multiple VDMs enabled.

If a FortiGate unit or VDM is operating in Transparent mode with WAN optimization enabled, WAN optimization uses the management IP address as the peer IP address of the FortiGate unit instead of the address of an interface.

## WAN optimization tunnels

All optimized traffic passes between the FortiGate units over a WAN optimization tunnel. Traffic in the tunnel can be sent in plain text or encrypted using AES-128bit-CBC SSL.

### WAN optimization tunnels

Both plain text and the encrypted tunnels use TCP destination port 7810.

Before a tunnel can be started, the peers must be configured to authenticate with each other. Then, the client-side peer attempts to start a WAN optimization tunnel with the server-side peer. Once the peers authenticate with each other, they bring up the tunnel and WAN optimization communication over the tunnel starts. After a tunnel has been established, multiple WAN optimization sessions can start and stop between peers without restarting the tunnel.

### Tunnel sharing

You can use the `tunnel-sharing` WAN optimization profile CLI keyword to configure tunnel sharing for WAN optimization rules. Tunnel sharing means multiple WAN optimization sessions share the same tunnel. Tunnel sharing can improve performance by reducing the number of WAN optimization tunnels between FortiGate units. Having fewer tunnels means less data to manage. Also, tunnel setup requires more than one exchange of information between the ends of the tunnel. Once the tunnel is set up, each new session that shares the tunnel avoids tunnel setup delays.

Tunnel sharing also uses bandwidth more efficiently by reducing the chances that small packets will be sent down the tunnel. Processing small packets reduces network throughput, so reducing the number of small packets improves performance. A shared tunnel can combine all the data from the sessions being processed by the tunnel and send the data together. For example, suppose a FortiGate unit is processing five WAN optimization sessions and each session has 100 bytes to send. If these sessions use a shared tunnel, WAN optimization combines the packets from all five sessions into one 500-byte packet. If each session uses its own private tunnel, five 100-byte

packets will be sent instead. Each packet also requires a TCP ACK reply. The combined packet in the shared tunnel requires one TCP ACK packet. The separate packets in the private tunnels require five.

Use the following command to configure tunnel sharing for HTTP traffic in a WAN optimization profile.

```
config wanopt profile
  edit default
    config http
      set tunnel-sharing {express-shared | private | shared}
    end
```

Tunnel sharing is not always recommended and may not always be the best practice. Aggressive and non-aggressive protocols should not share the same tunnel. An aggressive protocol can be defined as a protocol that is able to get more bandwidth than a non-aggressive protocol. (The aggressive protocols can “starve” the non-aggressive protocols.) HTTP and FTP are considered aggressive protocols. If aggressive and non-aggressive protocols share the same tunnel, the aggressive protocols may take all of the available bandwidth. As a result, the performance of less aggressive protocols could be reduced. To avoid this problem, rules for HTTP and FTP traffic should have their own tunnel. To do this, set `tunnel-sharing` to `private` for WAN optimization rules that accept HTTP or FTP traffic.

It is also useful to set `tunnel-sharing` to `express-shared` for applications, such as Telnet, that are very interactive but not aggressive. Express sharing optimizes tunnel sharing for Telnet and other interactive applications where latency or delays would seriously affect the user’s experience with the protocol.

Set `tunnel-sharing` to `shared` for applications that are not aggressive and are not sensitive to latency or delays. WAN optimization rules set to `sharing` and `express-shared` can share the same tunnel.

## WAN optimization and user and device identity policies, load balancing and traffic shaping

Please note the following about WAN optimization and firewall policies:

- WAN optimization is not compatible with firewall load balancing.
- WAN optimization is compatible with source and destination NAT options in firewall policies (including firewall virtual IPs). If a virtual IP is added to a policy the traffic that exits the WAN optimization tunnel has its destination address changed to the virtual IPs mapped to IP address and port.
- WAN optimization is compatible with user identity-based and device identity security policies. If a session is allowed after authentication or device identification the session can be optimized.

### Traffic shaping

Traffic shaping works for WAN optimization traffic that is not in a WAN optimization tunnel. So traffic accepted by a WAN optimization security policy on a client-side FortiGate unit can be shaped on ingress. However, when the traffic enters the WAN optimization tunnel, traffic shaping is not applied.

In manual mode:

- Traffic shaping works as expected on the client-side FortiGate unit.
- Traffic shaping cannot be applied to traffic on the server-side FortiGate unit.

In active-passive mode:

- Traffic shaping works as expected on the client-side FortiGate unit.
- If transparent mode is enabled in the WAN optimization profile, traffic shaping also works as expected on the

server-side FortiGate unit.

- If transparent mode is not enabled, traffic shaping works partially on the server-side FortiGate unit.

## WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended best practice HA configuration for WAN optimization is active-passive mode. When the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions.

You can also form a WAN optimization tunnel between a cluster and a standalone FortiGate unit or between two clusters.

In a cluster, only the primary unit stores the byte cache database. This database is not synchronized to the subordinate units. So, after a failover, the new primary unit must rebuild its byte cache. Rebuilding the byte cache can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGate unit that it is participating with in WAN optimization tunnels.

## WAN optimization, web caching and memory usage

To accelerate and optimize disk access and to provide better throughput and less latency FortiOS WAN optimization uses provisioned memory to reduce disk I/O and increase disk I/O efficiency. In addition, WAN optimization requires a small amount of additional memory per session for comprehensive flow control logic and efficient traffic forwarding.

When WAN optimization is enabled you will see a reduction in available memory. The reduction increases when more WAN optimization sessions are being processed. If you are thinking of enabling WAN optimization on an operating FortiGate unit, make sure its memory usage is not maxed out during high traffic periods.

In addition to using the system dashboard to see the current memory usage you can use the `get test wad 2` command to see how much memory is currently being used by WAN optimization. See "get test {wad | wccpd} <test\_level>" for more information.

## WAN Optimization Configuration

This chapter describes FortiGate WAN optimization client server architecture and other concepts you need to understand to be able to configure FortiGate WAN optimization.

### Manual (peer-to-peer) and active-passive WAN optimization

You can create **manual** (peer-to-peer) and **active-passive** WAN optimization configurations.

In reality, because WAN optimization traffic can only be processed by one CPU core, it is not recommended to increase the number of manual mode peers on the FortiGate unit per VDOM.

Note that the maximum number of manual peers are restricted to 256 per VDOM. However, in Active-Passive configurations, there is no hard-limit to the maximum number of manual peers per VDOM.

## Manual (peer to peer) configurations

Manual configurations allow for WAN optimization between one client-side FortiGate unit and one server-side FortiGate unit. To create a manual configuration you add a **manual mode** WAN optimization security policy to the client-side FortiGate unit. The manual mode policy includes the peer ID of a server-side FortiGate unit.

In a manual mode configuration, the client-side peer can only connect to the named server-side peer. When the client-side peer initiates a tunnel with the server-side peer, the packets that initiate the tunnel include extra information so that the server-side peer can determine that it is a peer-to-peer tunnel request. This extra information is required because the server-side peer does not require a WAN optimization policy; however, you need to add the client peer host ID and IP address to the server-side FortiGate unit peer list.

In addition, from the server-side FortiGate unit CLI you must add an Explicit Proxy security policy with `proxy` set to `wanopt` and the destination interface and network set to the network containing the servers that clients connect to over the WAN optimization tunnel. WAN optimization tunnel requests are accepted by the explicit proxy policy and if the client-side peer is in the server side peer's address list the traffic is forwarded to the servers on the destination network.

### Manual mode client-side policy

You must configure manual mode client-side policies from the CLI. From the GUI a manual mode policy has WAN Optimization turned on and includes the following text beside the *WAN optimization* field: *Manual (Profile: <profile-name>. Peer: <peer-name>.*

Add a manual mode policy to the client-side FortiGate unit from the CLI. The policy enables WAN optimization, sets `wanopt-detection` to `off`, and uses the `wanopt-peer` option to specify the server-side peer. The following example uses the default WAN optimization profile.

```
config firewall policy
  edit 2
    set srcintf internal
    set dstintf wan1
    set srcaddr client-subnet
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL
    set wanopt enable
    set wanopt-detection off
    set wanopt-profile default
    set wanopt-peer server
  next
end
```

### Manual mode server-side explicit proxy policy

The server-side explicit proxy policy allows connections from the WAN optimization tunnel to the server network by setting the proxy type to `wanopt`. You must add policies that set `proxy` to `wanopt` from the CLI and these policies do not appear on the GUI. The policy should look like the following:

```
configure firewall proxy-policy
  edit 3
    set proxy wanopt
    set dstintf internal
    set srcaddr all
    set dstaddr server-subnet
```

```
        set action accept
        set schedule always
        set service ALL
    next
end
```

## Active-passive configurations

Active-passive WAN optimization requires an **active** WAN optimization policy on the client-side FortiGate unit and a **passive** WAN optimization policy on the server-side FortiGate unit. The server-side FortiGate unit also requires an explicit proxy policy with `proxy` set to `wanopt`.

You can use the passive policy to control WAN optimization address translation by specifying **transparent mode** or non-transparent mode. See [Manual \(peer-to-peer\) and active-passive WAN optimization on page 975](#). You can also use the passive policy to apply security profiles, web caching, and other FortiGate features at the server-side FortiGate unit. For example, if a server-side FortiGate unit is protecting a web server, the passive policy could enable web caching.

A single passive policy can accept tunnel requests from multiple FortiGate units as long as the server-side FortiGate unit includes their peer IDs and all of the client-side FortiGate units include the server-side peer ID.

## Active client-side policy

Add an active policy to the client-side FortiGate unit by turning on **WAN Optimization** and selecting **active**. Then select a WAN optimization **Profile**. From the CLI the policy could look like the following:

```
config firewall policy
  edit 2
    set srcintf internal
    set dstintf wan1
    set srcaddr client-subnet
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL
    set wanopt enable
    set wanopt-detection active
    set wanopt-profile default
  next
end
```

## Server-side tunnel policy

The server-side requires an explicit proxy policy that sets the `proxy` to `wanopt`. You must add this policy from the CLI and policies with `proxy` set to `wanopt` do not appear on the GUI. From the CLI the policy could look like the following:

```
configure firewall proxy-policy
  edit 3
    set proxy wanopt
    set dstintf internal
    set srcaddr all
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL
  next
```

```
end
```

### Server-side passive policy

Add a passive policy to the server-side FortiGate unit by selecting **Enable WAN Optimization** and selecting **passive**. Then set the **Passive Option** to **transparent**. From the CLI the policy could look like the following:

```
config firewall policy
edit 2
    set srcintf "wan1"
    set dstintf "internal"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set wanopt enable
    set wanopt-detection passive
    set wanopt-passive-opt transparent
next
```

## WAN optimization profiles

Use WAN optimization profiles to apply WAN optimization techniques to traffic to be optimized. In a WAN optimization profile you can select the protocols to be optimized and for each protocol you can enable SSL offloading (if supported), secure tunneling, byte caching and set the port or port range the protocol uses. You can also enable transparent mode and optionally select an authentication group. You can edit the default WAN optimization profile or create new ones.

To configure a WAN optimization profile go to **WAN Opt. & Cache > Profiles** and edit a profile or create a new one.

### Configuring a WAN optimization profile

Edit WAN Optimization Profile

default

Name

default

Comments

default WANopt profile

22/255

☒ Transparent Mode

☒ Authentication Group

Auth-Grp

Protocol	SSL Offloading	Secure Tunneling	Byte Caching	Port
<input checked="" type="checkbox"/> CIFS		<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	445
<input checked="" type="checkbox"/> FTP		<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	21
<input checked="" type="checkbox"/> HTTP	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	80
<input checked="" type="checkbox"/> MAPI		<input type="checkbox"/>	<input checked="" type="checkbox"/>	135
<input checked="" type="checkbox"/> TCP	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	1-65535

From the CLI you can use the following command to configure a WAN optimization profile to optimize HTTP traffic.

```
config wanopt profile
edit new-profile
```

```

config http
    set status enable
end

```

<b>Transparent Mode</b>	<p>Servers receiving packets after WAN optimization “see” different source addresses depending on whether or not you select <b>Transparent Mode</b>.</p> <p>For more information, see <a href="#">WAN optimization profiles on page 978</a>.</p>
<b>Authentication Group</b>	<p>Select this option and select an authentication group so that the client and server-side FortiGate units must authenticate with each other before starting the WAN optimization tunnel. You must also select an authentication group if you select <b>Secure Tunneling</b> for any protocol.</p> <p>You must add identical authentication groups to both of the FortiGate units that will participate in the WAN optimization tunnel. For more information, see <a href="#">Configuring authentication groups on page 1</a>.</p>
<b>Protocol</b>	<p>Select CIFS, FTP, HTTP or MAPI to apply protocol optimization for the selected protocols. See <a href="#">WAN optimization profiles on page 978</a>.</p> <p>Select TCP if the WAN optimization tunnel accepts sessions that use more than one protocol or that do not use the CIFS, FTP, HTTP, or MAPI protocol.</p>
<b>SSL Offloading</b>	<p>Select to apply SSL offloading for HTTPS or other SSL traffic. You can use SSL offloading to offload SSL encryption and decryption from one or more HTTP servers to the FortiGate unit. If you enable this option, you must configure the security policy to accept SSL-encrypted traffic.</p> <p>If you enable SSL offloading, you must also use the CLI command <code>config firewall ssl-server</code> to add an SSL server for each HTTP server that you want to offload SSL encryption/decryption for. For more information, see <a href="#">Turning on web caching for HTTPS traffic on page 1</a>.</p>
<b>Secure Tunneling</b>	<p>The WAN optimization tunnel is encrypted using SSL encryption. You must also add an authentication group to the profile. For more information, see <a href="#">Secure tunneling on page 1</a>.</p>
<b>Byte Caching</b>	<p>Select to apply WAN optimization byte caching to the sessions accepted by this rule. For more information, see <a href="#">“Byte caching”</a>.</p>
<b>Port</b>	<p>Enter a single port number or port number range. Only packets whose destination port number matches this port number or port number range will be optimized.</p>

### Processing non-HTTP sessions accepted by a WAN optimization profile with HTTP optimization

From the CLI, you can use the following command to configure how to process non-HTTP sessions when a rule configured to accept and optimize HTTP traffic accepts a non-HTTP session. This can occur if an application sends non-HTTP sessions using an HTTP destination port.

```
config wanopt profile
  edit default
    config http
      set status enable
      set tunnel-non-http {disable | enable}
    end
```

To drop non-HTTP sessions accepted by the rule set `tunnel-non-http` to `disable`, or set it to `enable` to pass non-HTTP sessions through the tunnel without applying protocol optimization, byte-caching, or web caching. In this case, the FortiGate unit applies TCP protocol optimization to non-HTTP sessions.

### Processing unknown HTTP sessions

Unknown HTTP sessions are HTTP sessions that do not comply with HTTP 0.9, 1.0, or 1.1. From the CLI, use the following command to specify how a rule handles such HTTP sessions.

```
config wanopt profile
  edit default
    config http
      set status enable
      set unknown-http-version {best-effort | reject | tunnel}
    end
```

To assume that all HTTP sessions accepted by the rule comply with HTTP 0.9, 1.0, or 1.1, select `best-effort`. If a session uses a different HTTP version, WAN optimization may not parse it correctly. As a result, the FortiGate unit may stop forwarding the session and the connection may be lost. To reject HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, select `reject`.

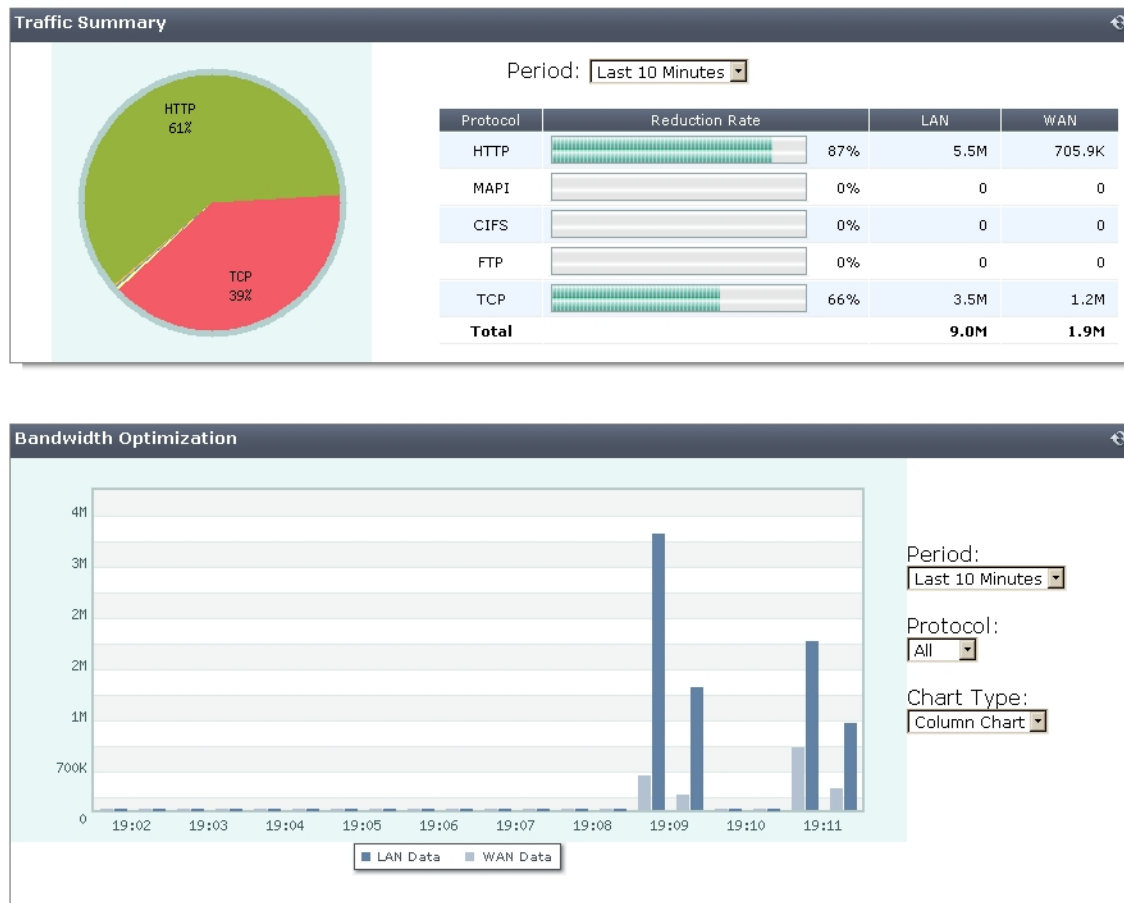

To pass HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, but without applying HTTP protocol optimization, byte-caching, or web caching, you can also select `tunnel`. TCP protocol optimization is applied to these HTTP sessions.

### Monitoring WAN optimization performance

Using WAN optimization monitoring, you can confirm that a FortiGate unit is optimizing traffic and view estimates of the amount of bandwidth saved. The WAN optimization monitor presents collected log information in a graphical format to show network traffic summary and bandwidth optimization information.

To view the WAN optimization monitor, go to **Monitor > WAN Opt. Monitor**.

## WAN optimization monitor

### Traffic Summary

The traffic summary shows how WAN optimization is reducing the amount of traffic on the WAN for each WAN optimization protocol by showing the traffic reduction rate as a percentage of the total traffic. The traffic summary also shows the amount of WAN and LAN traffic. If WAN optimization is being effective the amount of WAN traffic should be lower than the amount of LAN traffic.

You can use the refresh icon to update the traffic summary display at any time. You can also set the amount of time for which the traffic summary shows data. The time period can vary from the last 10 minutes to the last month.

### Bandwidth Optimization

This section shows network bandwidth optimization per time period. A line or column chart compares an application's pre-optimized size (LAN data) with its optimized size (WAN data). You can select the chart type, the monitoring time period, and the protocol for which to display data. If WAN optimization is being effective the WAN bandwidth should be lower than the LAN bandwidth.

## WAN optimization configuration summary

This section includes a client-side and a server-side WAN Optimization configuration summary.:

## Client-side configuration summary

### WAN optimization profile

Enter the following command to view WAN optimization profile CLI options:

```
tree wanopt profile
-- [profile] --*name (36)
  |- transparent
  |- comments
  |- auth-group (36)
  |- <http> -- status
    |- secure-tunnel
    |- byte-caching
    |- prefer-chunking
    |- tunnel-sharing
    |- log-traffic
    |- port (1,65535)
    |- ssl
    |- ssl-port (1,65535)
    |- unknown-http-version
    +- tunnel-non-http
  |- <cifs> -- status
    |- secure-tunnel
    |- byte-caching

    +- ssl-port (1,65535)
```

### Local host ID and peer settings

```
config wanopt settings
  set host-id client
end
```

```

config wanopt peer
    edit server
        set ip 10.10.2.82
    end

```

## Security policies

Two client-side WAN optimization security policy configurations are possible. One for active-passive WAN optimization and one for manual WAN optimization.

### Active/passive mode on the client-side

```

config firewall policy
    edit 2
        set srcintf internal
        set dstintf wan1
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set wanopt enable <<< enable WAN optimization
        set wanopt-detection active <<< set the mode to active/passive
        set wanopt-profile "default" <<< select the wanopt profile
    next
end

```

### Manual mode on the client-side

```

config firewall policy
    edit 2
        set srcintf internal
        set dstintf wan1
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set wanopt enable <<< enable WAN optimization
        set wanopt-detection off <<< sets the mode to manual
        set wanopt-profile "default" <<< select the wanopt profile
        set wanopt-peer "server" <<< set the only peer to do wanopt
                                (required for manual mode)
    next
end

```

with

## server-side configuration summary

### Local host ID and peer settings

```

config wanopt settings
    set host-id server
end
config wanopt peer
    edit client
        set ip 10.10.2.81
    end

```

```
end
```

## Security policies

Two server-side WAN optimization security policy configurations are possible. One for active-passive WAN optimization and one for manual WAN optimization.

### Active/passive mode on server-side

```
config firewall policy
edit 2 <<< the passive mode policy
    set srcintf wan1
    set dstintf internal
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
    set wanopt enable
    set wanopt-detection passive
    set wanopt-passive-opt transparent
end
config firewall proxy-policy
edit 3 <<< policy that accepts wanopt tunnel connections from the server
    set proxy wanopt <<< wanopt proxy type
    set dstintf internal
    set srcaddr all
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL
next
end
```

### Manual mode on server-side

```
config firewall proxy-policy
edit 3 <<< policy that accepts wanopt tunnel connections from the client
    set proxy wanopt <<< wanopt proxy type
    set dstintf internal
    set srcaddr all
    set dstaddr server-subnet
    set action accept
    set schedule always
    set service ALL
next
end
```

## Best practices

This is a short list of WAN optimization and explicit proxy best practices.

- WAN optimization tunnel sharing is recommended for similar types of WAN optimization traffic. However, tunnel sharing for different types of traffic is not recommended. For example, aggressive and non-aggressive protocols should not share the same tunnel. See [Best practices on page 984](#).

- Active-passive HA is the recommended HA configuration for WAN optimization. See [Best practices on page 984](#).
- Configure WAN optimization authentication with specific peers. Accepting any peer is not recommended as this can be less secure. See [Accepting any peers on page 1](#).
- Set the explicit proxy **Default Firewall Policy Action** to **Deny**. This means that a security policy is required to use the explicit web proxy. See [General explicit web proxy configuration steps on page 1](#).
- Set the explicit FTP proxy **Default Firewall Policy Action** to **Deny**. This means that a security policy is required to use the explicit FTP proxy. See [General explicit FTP proxy configuration steps on page 1](#).
- Do not enable the explicit web or FTP proxy on an interface connected to the Internet. This is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you must enable the proxy on such an interface make sure authentication is required to use the proxy. See [General explicit web proxy configuration steps on page 1](#).

## Example Basic manual (peer-to-peer) WAN optimization configuration

In a manual (peer to peer) configuration the WAN optimization tunnel can be set up between one client-side FortiGate unit and one server-side FortiGate unit. The peer ID of the server-side FortiGate unit is added to the client-side WAN optimization policy. When the client-side FortiGate unit initiates a tunnel with the server-side FortiGate unit, the packets that initiate the tunnel include information that allows the server-side FortiGate unit to determine that it is a manual tunnel request. The server-side FortiGate unit does not require a WAN optimization profile; you just need to add the client peer host ID and IP address to the server-side FortiGate unit peer list and from the CLI an explicit proxy policy to accept WAN optimization tunnel connections.

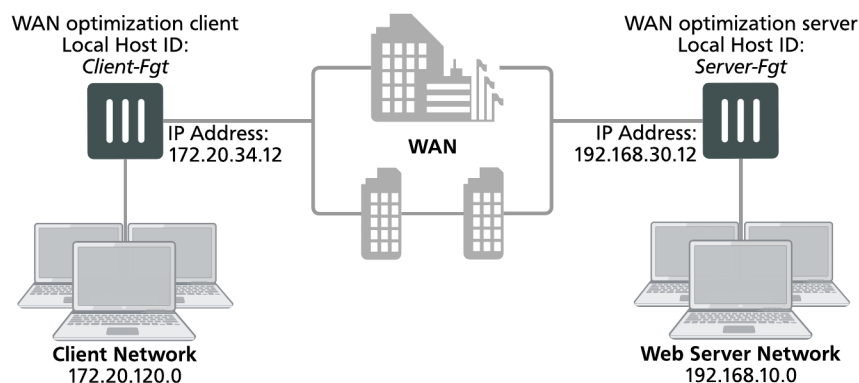

In a manual WAN optimization configuration, you create a manual WAN optimization security policy on the client-side FortiGate unit. To do this you must use the CLI to set `wanopt-detection` to `off` and to add the peer host ID of the server-side FortiGate unit to the WAN optimization security policy.

### Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Client-Fgt with a WAN IP address of 172.20.34.12. This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Server\_Fgt with a WAN IP address of 192.168.30.12. This unit is in front of a web server network with IP address 192.168.10.0.

This example customizes the default WAN optimization profile on the client-side FortiGate unit and adds it to the WAN optimization policy. You can also create a new WAN optimization profile.

### Example manual (peer-to-peer) topology

## General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
  - Add peers.
  - Configure the default WAN optimization profile to optimize HTTP traffic.
  - Add a manual WAN optimization security policy.
2. Configure the server-side FortiGate unit:
  - Add peers.
  - Add a WAN optimization tunnel policy.

## Configuring basic peer-to-peer WAN optimization - web-based manager

Use the following steps to configure the example configuration from the web-based manager.

### To configure the client-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

<b>Local Host ID</b>	Client-Fgt
----------------------	------------

2. Select **Apply**.
3. Select **Create New** and add the server-side FortiGate unit **Peer Host ID** and **IP Address** for the server-side FortiGate:

<b>Peer Host ID</b>	Server-Fgt
<b>IP Address</b>	192.168.30.12

4. Select **OK**.
5. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

<b>Category</b>	Address
<b>Name</b>	Client-Net
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	172.20.120.0/24
<b>Interface</b>	port1

6. Select **Create New** to add a firewall address for the web server network.

<b>Category</b>	Address
<b>Name</b>	Web-Server-Net

<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	192.168.10.0/24
<b>Interface</b>	port2

- Go to **WAN Opt. & Cache > Profiles** and edit the default profile.
- Select **Transparent Mode**.
- Under Protocol, select **HTTP** and for HTTP select **Byte Caching**. Leave the HTTP **Port** set to 80.
- Select **Apply** to save your changes.
- Go to **Policy & Objects > IPv4 Policy** and add a WAN optimization security policy to the client-side FortiGate unit that accepts traffic to be optimized:

<b>Incoming Interface</b>	port1
<b>Source Address</b>	all
<b>Outgoing Interface</b>	port2
<b>Destination Address</b>	all
<b>Schedule</b>	always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT

- Select **Enable WAN Optimization** and configure the following settings:

<b>Enable WAN Optimization</b>	active
<b>Profile</b>	default

- Select **OK**.
- Edit the policy from the CLI to turn off `wanopt-detection`, add the peer ID of the server-side FortiGate unit, and the default WAN optimization profile. The following example assumes the ID of the policy is 5:

```
config firewall policy
  edit 5
    set wanopt-detection off
    set wanopt-peer Server-Fgt
    set wanopt-profile default
  end
```

When you set the detection mode to `off` the policy becomes a manual mode WAN optimization policy. On the web-based manager the WAN optimization part of the policy changes to the following:

<b>Enable WAN Optimization</b>	Manual (Profile: default, Peer: Peer-Fgt-2)
--------------------------------	---

### To configure the server-side FortiGate unit

- Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

<b>Local Host ID</b>	Server-Fgt
----------------------	------------

2. Select **Apply**.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

<b>Peer Host ID</b>	Client-Fgt
<b>IP Address</b>	172.20.34.12

4. Select **OK**.
5. Enter the following CLI command to add an explicit proxy policy to accept WAN optimization tunnel connections.

```
configure firewall proxy-policy
edit 0
    set proxy wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
next
end
```

## Configuring basic peer-to-peer WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

### To configure the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
    set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
    edit Server-Fgt
        set ip 192.168.30.12
    end
```

3. Add a firewall address for the client network.

```
config firewall address
    edit Client-Net
        set type ipmask
        set subnet 172.20.120.0 255.255.255.0
        set associated-interface port1
    end
```

4. Add a firewall address for the web server network.

```
config firewall address
    edit Web-Server-Net
        set type ipmask
```

```
set subnet 192.168.10.0 255.255.255.0
set associated-interface port2
end
```

5. Edit the default WAN optimization profile, select transparent mode, enable HTTP WAN optimization and enable byte caching for HTTP. Leave the HTTP Port set to 80.

```
config wanopt profile
edit default
set transparent enable
config http
set status enable
set byte-caching enable
end
end
```

6. Add a WAN optimization security policy to the client-side FortiGate unit to accept the traffic to be optimized:

```
config firewall policy
edit 0
set srcintf port1
set dstintf port2
set srcaddr all
set dstaddr all
set action accept
set service ALL
set schedule always
set wanopt enable
set wanopt-profile default
set wanopt-detection off
set wanopt-peer Server-Fgt
end
```

### To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
edit Client-Fgt
set ip 192.168.30.12
end
```

3. Add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
edit 0
set proxy wanopt
set dstintf port1
set srcaddr all
set dstaddr all
set action accept
set schedule always
set service ALL
next
```

end

## Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the client network and the web server network. For example, from a PC on the client network browse to the IP address of a web server on the web server network, for example `http://192.168.10.100`. Even though this address is not on the client network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring. If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the client-side FortiGate unit is accepting traffic for the 192.168.10.0 network. You can do this by checking the policy monitor (**Monitor > Firewall User Monitor**). Look for sessions that use the policy ID of this policy.
- Check routing on the FortiGate units and on the client and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the client network must allow packets destined for the web server network to be received by the client-side FortiGate unit, and packets from the server-side FortiGate unit must be able to reach the web servers.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating.

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output for the client-side FortiGate unit shows 10 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to off).

```
diagnose wad tunnel list

Tunnel: id=100 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web-servers id=100 ip=192.168.30.12
  SSL-secured-tunnel=no auth-grp=
  bytes_in=348 bytes_out=384

Tunnel: id=99 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web-servers id=99 ip=192.168.30.12
  SSL-secured-tunnel=no auth-grp=

Tunnel: id=2 type=manual
  vd=0 shared=no uses=0 state=3
  peer name=Web-servers id=2 ip=192.168.30.12
  SSL-secured-tunnel=no auth-grp=
  bytes_in=1228 bytes_out=1264

Tunnels total=10 manual=10 auto=0
```

## Example Active-passive WAN optimization

In active-passive WAN optimization you add an active WAN optimization policy to the client-side FortiGate unit and you add a WAN optimization tunnel policy and a passive WAN optimization policy to the server-side FortiGate unit.

The active policy accepts the traffic to be optimized and sends it down the WAN optimization tunnel to the server-side FortiGate unit. The active policy can also apply security profiles and other features to traffic before it exits the client-side FortiGate unit.

A tunnel explicit proxy policy on the server-side FortiGate unit allows the server-side FortiGate unit to form a WAN optimization tunnel with the client-side FortiGate unit. The passive WAN optimization policy is required because of the active policy on the client-side FortiGate unit. You can also use the passive policy to apply WAN optimization transparent mode and features such as security profiles, logging, traffic shaping and web caching to the traffic before it exits the server-side FortiGate unit.

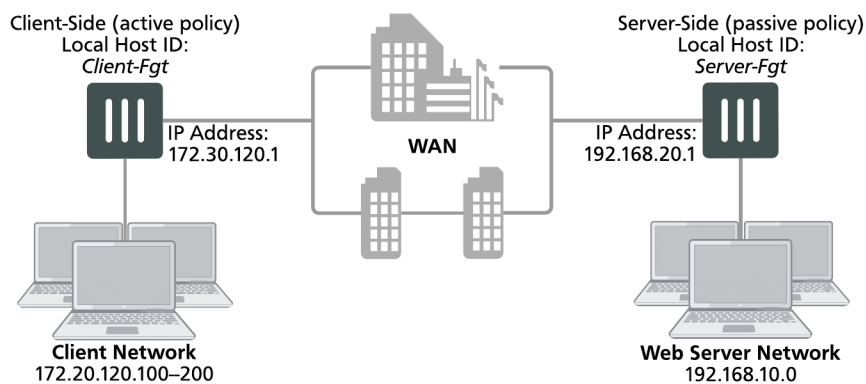

## Network topology and assumptions

On the client-side FortiGate unit this example configuration includes a WAN optimization profile that optimizes CIFS, HTTP, and FTP traffic and an active WAN optimization policy. The active policy also applies virus scanning to the WAN optimization traffic.

On the server-side FortiGate unit, the passive policy applies application control to the WAN optimization traffic.

In this example, WAN optimization transparent mode is selected in the WAN optimization profile and the passive WAN optimization policy accepts this transparent mode setting. This means that the optimized packets maintain their original source and destination addresses. As a result, routing on the client network must be configured to route packets for the server network to the client-side FortiGate unit. Also the routing configuration on the server network must be able to route packets for the client network to the server-side FortiGate unit.

### Example active-passive WAN optimization topology

## General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
  - Add peers.
  - Add a WAN optimization profile to optimize CIFS, FTP, and HTTP traffic.
  - Add firewall addresses for the client and web server networks.
  - Add an active WAN optimization policy.
2. Configure the server-side FortiGate unit by:
  - Add peers.
  - Add firewall addresses for the client and web server networks.
  - Add a passive WAN optimization policy.
  - Add a WAN optimization tunnel policy.

## Configuring basic active-passive WAN optimization - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager.

**To configure the client-side FortiGate unit**

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

<b>Local Host ID</b>	Client-Fgt
----------------------	------------

2. Select **Apply**.
3. Select **Create New** and add a Peer Host ID and the **IP Address** for the server-side FortiGate unit:

<b>Peer Host ID</b>	Server-Fgt
<b>IP Address</b>	192.168.20.1

4. Select **OK**.
5. Go to **WAN Opt. & Cache > Profiles** and select **Create New** to add a WAN optimization profile to optimize CIFS, HTTP, and FTP traffic:

<b>Name</b>	Custom-wan-opt-pro
<b>Transparent Mode</b>	Select

6. Select the **CIFS** protocol, select **Byte Caching** and set the **Port** to 445.
7. Select the **FTP** protocol, select **Byte Caching** and set the **Port** to 21.
8. Select the **HTTP** protocol, select **Byte Caching** and set the **Port** to 80.
9. Select **OK**.
10. Go to **Policy & Objects > Addresses** and select **Create New** to add an address for the client network.

<b>Category</b>	Address
<b>Address Name</b>	Client-Net
<b>Type</b>	IP Range
<b>Subnet / IP Range</b>	172.20.120.100-172.20.120.200
<b>Interface</b>	port1

11. Select **Create New** to add an address for the web server network.

<b>Category</b>	Address
<b>Address Name</b>	Web-Server-Net
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	192.168.10.0/24
<b>Interface</b>	port2

12. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add an active WAN optimization security policy:

<b>Incoming Interface</b>	port1
<b>Source Address</b>	Client-Net
<b>Outgoing Interface</b>	port2
<b>Destination Address</b>	Web-Server-Net
<b>Schedule</b>	always
<b>Service</b>	HTTP FTP SMB
<b>Action</b>	ACCEPT

13. Turn on **WAN Optimization** and configure the following settings:

<b>WAN Optimization</b>	active
<b>Profile</b>	Custom-wan-opt-pro

14. Turn on Antivirus and select the **default** antivirus profile.  
15. Select **OK**.

#### To configure the server-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

<b>Local Host ID</b>	Server-Fgt
----------------------	------------

2. Select **Apply**.  
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

<b>Peer Host ID</b>	Client-Fgt
<b>IP Address</b>	172.30.120.1

4. Select **OK**.  
5. Go to **Policy & Objects > Addresses** and select **Create New** to add an address for the client network.

<b>Category</b>	Address
<b>Address Name</b>	Client-Net
<b>Type</b>	IP Range
<b>Subnet / IP Range</b>	172.20.120.100-172.20.120.200
<b>Interface</b>	port1

6. Select **Create New** to add a firewall address for the web server network.

<b>Category</b>	Address
<b>Address Name</b>	Web-Server-Net
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	192.168.10.0/24
<b>Interface</b>	port2

7. Select **OK**.
8. Select **Policy & Objects > IPv4 Policy** and select **Create New** to add a passive WAN optimization policy that applies application control.

<b>Incoming Interface</b>	port2
<b>Source Address</b>	Client-Net
<b>Outgoing Interface</b>	port1
<b>Destination Address</b>	Web-Server-Net
<b>Schedule</b>	always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT

9. Turn on **WAN Optimization** and configure the following settings:

<b>WAN Optimization</b>	passive
<b>Passive Option</b>	default

10. Select **OK**.
11. From the CLI enter the following command to add a WAN optimization tunnel explicit proxy policy.

```

configure firewall proxy-policy
edit 0
set proxy wanopt
set dstintf port1
set srcaddr all
set dstaddr all
set action accept
set schedule always
set service ALL
next
end

```

## Configuring basic active-passive WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

**To configure the client-side FortiGate unit**

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
  set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
  edit Server-Fgt
  set ip 192.168.20.1
end
```

3. Add a WAN optimization profile to optimize CIFS, HTTP, and FTP traffic.

```
config wanopt profile
  edit Custom-wan-opt-pro
    config cifs
      set status enable
      set byte-caching enable
      set port 445
    end
    config http
      set status enable
      set byte-caching enable
      set port 80
    end
    config ftp
      set status enable
      set byte-caching enable
      set port 21
    end
  end
end
```

4. Add a firewall address for the client network.

```
config firewall address
  edit Client-Net
    set type iprange
    set start-ip 172.20.120.100
    set end-ip 172.20.120.200
    set associated-interface port1
  end
```

5. Add a firewall address for the web server network.

```
config firewall address
  edit Web-Server-Net
    set type ipmask
    set subnet 192.168.10.0 255.255.255.0
    set associated-interface port2
  end
```

6. Add an active WAN optimization security policy that applies virus scanning:

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr Client-net
    set dstaddr Web-Server-Net
    set action accept
    set service HTTP FTP SMB
    set schedule always
```

```
set wanopt enable
set wanopt-detection active
set wanopt-profile Custom-wan-opt-pro
end
```

### To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
edit Client-Fgt
set ip 172.20.120.1
end
```

3. Add a firewall address for the client network.

```
config firewall address
edit Client-Net
set type iprange
set start-ip 172.20.120.100
set end-ip 172.20.120.200
set associated-interface port1
end
```

4. Add a firewall address for the web server network.

```
config firewall address
edit Web-Server-Net
set type ipmask
set subnet 192.168.10.0 255.255.255.0
set associated-interface port2
end
```

5. Add a passive WAN optimization policy.

```
config firewall policy
edit 0
set srcintf port1
set dstintf port2
set srcaddr Client-Net
set dstaddr Web-Server-Net
set action accept
set service ALL
set schedule always
set wanopt enable
set wanopt-detection passive
set wanopt-passive-opt default
end
```

6. Add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
edit 0
set proxy wanopt
set dstintf port1
set srcaddr all
set dstaddr all
set action accept
set schedule always
set service ALL
```

```

    next
end

```

## Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the client network and the web server network. For example, from a PC on the client network browse to the IP address of a web server on the web server network, for example `http://192.168.10.100`. Even though this address is not on the client network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring. If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the Client-Side FortiGate unit is accepting traffic for the 192.168.10.0 network and that this security policy does not include security profiles. You can do this by checking the FortiGate session table from the dashboard. Look for sessions that use the policy ID of this policy.
- Check routing on the FortiGate units and on the client and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the client network must allow packets destined for the web server network to be received by the client-side FortiGate unit, and packets from the server-side FortiGate unit must be able to reach the web servers etc.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output shows 3 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to on).

```

diagnose wad tunnel list

Tunnel: id=139 type=auto
    vd=0 shared=no uses=0 state=1
    peer name= id=0 ip=unknown
    SSL-secured-tunnel=no auth-grp=test
    bytes_in=744 bytes_out=76

Tunnel: id=141 type=auto
    vd=0 shared=no uses=0 state=1
    peer name= id=0 ip=unknown
    SSL-secured-tunnel=no auth-grp=test
    bytes_in=727 bytes_out=76

Tunnel: id=142 type=auto
    vd=0 shared=no uses=0 state=1
    peer name= id=0 ip=unknown
    SSL-secured-tunnel=no auth-grp=test
    bytes_in=727 bytes_out=76

Tunnels total=3 manual=0 auto=3

```

## Example Adding secure tunneling to an active-passive WAN optimization configuration

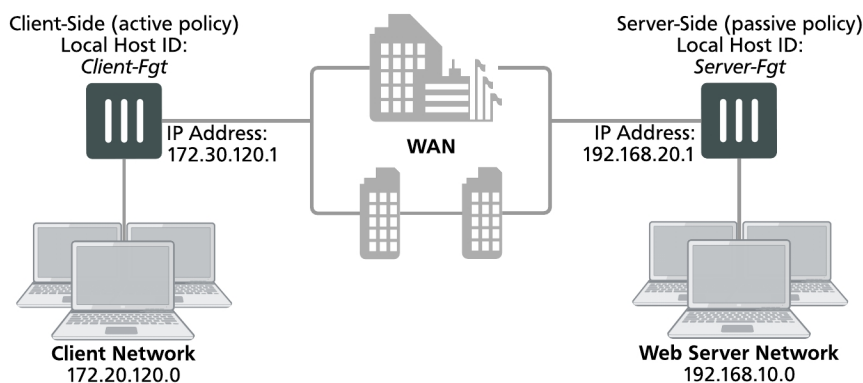

This example shows how to configure two FortiGate units for active-passive WAN optimization with secure tunneling. The same authentication group is added to both FortiGate units. The authentication group includes a password (or pre-shared key) and has **Peer Acceptance** set to **Accept any Peer**. An active policy is added to the client-side FortiGate unit and a passive policy to the server-side FortiGate unit. The active policy includes a profile that performs secure tunneling, optimizes HTTP traffic, and uses Transparent Mode and byte caching.

The authentication group is named **Auth-Secure-Tunnel** and the password for the pre-shared key is **2345678**. The topology for this example is shown below. This example includes web-based manager configuration steps followed by equivalent CLI configuration steps. For information about secure tunneling, see [Secure tunneling on page 1](#).

### Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Client-net with a WAN IP address of 172.30.120.1. This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Web-servers and has a WAN IP address of 192.168.20.1. This unit is in front of a web server network with IP address 192.168.10.0.

### Example active-passive WAN optimization and secure tunneling topology

### General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
  - Add peers.
  - Add an authentication group.
  - Add an active WAN optimization policy.
2. Configure the server-side FortiGate unit.
  - Add peers.
  - Add the same authentication group
  - Add a passive WAN optimization policy that applies application control.
  - Add a WAN optimization tunnel policy.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

### Configuring WAN optimization with secure tunneling - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager. (CLI steps follow.)

#### To configure the client-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the client-side FortiGate unit:

<b>Local Host ID</b>	Client-Fgt
----------------------	------------

2. Select **Apply** to save your setting.
3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the server-side FortiGate unit:

<b>Peer Host ID</b>	Server-Fgt
<b>IP Address</b>	192.168.20.1

4. Select **OK**.
5. Go to **WAN Opt. & Cache > Authentication Groups** and select **Create New** to add the authentication group to be used for secure tunneling:

<b>Name</b>	Auth-Secure-Tunnel
<b>Authentication Method</b>	Pre-shared key
<b>Password</b>	2345678
<b>Peer Acceptance</b>	Accept Any Peer

6. Select **OK**.
7. Go to **WAN Opt. & Cache > Profiles** and select **Create New** to add a WAN optimization profile that enables secure tunneling and includes the authentication group:

<b>Name</b>	Secure-wan-op-pro
<b>Transparent Mode</b>	Select
<b>Authentication Group</b>	Auth-Secure-tunnel

8. Select the **HTTP** protocol, select Secure Tunneling and **Byte Caching** and set the **Port** to 80.
9. Select **OK**.
10. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

<b>Category</b>	Address
-----------------	---------

<b>Name</b>	Client-Net
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	172.20.120.0/24
<b>Interface</b>	port1

11. Select **Create New** to add a firewall address for the web server network.

<b>Category</b>	Address
<b>Address Name</b>	Web-Server-Net
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	192.168.10.0/24
<b>Interface</b>	port2

12. Go to **Policy & Objects > IPv4 Policy** and select **Create New** to add an active WAN optimization security policy:

<b>Incoming Interface</b>	port1
<b>Source Address</b>	Client-Net
<b>Outgoing Interface</b>	port2
<b>Destination Address</b>	Web-Server-Net
<b>Schedule</b>	always
<b>Service</b>	HTTP
<b>Action</b>	ACCEPT

13. Turn on **WAN Optimization** and configure the following settings:

<b>WAN Optimization</b>	active
<b>Profile</b>	Secure-wan-opt-pro

14. Select **OK**.

#### To configure the server-side FortiGate unit

1. Go to **WAN Opt. & Cache > Peers** and enter a **Local Host ID** for the server-side FortiGate unit:

<b>Local Host ID</b>	Server-Fgt
----------------------	------------

2. Select **Apply** to save your setting.  
 3. Select **Create New** and add a **Peer Host ID** and the **IP Address** for the client-side FortiGate unit:

<b>Peer Host ID</b>	Client-Fgt
<b>IP Address</b>	172.30.120.1

4. Select **OK**.
5. Go to **WAN Opt. & Cache > Authentication Groups** and select **Create New** and add an authentication group to be used for secure tunneling:

<b>Name</b>	Auth-Secure-Tunnel
<b>Authentication Method</b>	Pre-shared key
<b>Password</b>	2345678
<b>Peer Acceptance</b>	Accept Any Peer

6. Select **OK**.
7. Go to **Policy & Objects > Addresses** and select **Create New** to add a firewall address for the client network.

<b>Category</b>	Address
<b>Name</b>	Client-Net
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	172.20.120.0/24
<b>Interface</b>	port1

8. Select **Create New** to add a firewall address for the web server network.

<b>Category</b>	Address
<b>Address Name</b>	Web-Server-Net
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	192.168.10.0/24
<b>Interface</b>	port2

9. Select **OK**.
10. Select **Create New** to add a passive WAN optimization policy that applies application control.

<b>Incoming Interface</b>	port2
<b>Source Address</b>	Client-Net
<b>Outgoing Interface</b>	port1
<b>Destination Address</b>	Web-Server-Net

<b>Schedule</b>	always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT

11. Turn on **WAN Optimization** and configure the following settings:

<b>WAN Optimization</b>	passive
<b>Passive Option</b>	default

12. Select **OK**.
13. From the CLI enter the following command to add a WAN optimization tunnel explicit proxy policy.

```
configure firewall proxy-policy
edit 0
    set proxy wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
next
end
```

## Configuring WAN optimization with secure tunneling - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

### To the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
    set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
edit Server-Fgt
    set ip 192.168.20.1
end
```

3. Add a new authentication group to be used for secure tunneling:

```
config wanopt auth-group
edit Auth-Secure-Tunnel
    set auth-method psk
    set psk 2345678
end
```

Leave `peer-accept` at its default value.

4. Add a WAN optimization profile that enables secure tunneling and includes the authentication group, enables HTTP protocol optimization, and enables secure tunneling and byte caching for HTTP traffic:

```
config wanopt profile
edit Secure-wan-op-pro
set auth-group Auth-Secure-Tunnel
config http
set status enable
set secure-tunnel enable
set byte-caching enable
set port 80
end
end
```

5. Add a firewall address for the client network.

```
config firewall address
edit Client-Net
set type ipmask
set subnet 172.20.120.0 255.255.255.0
set associated-interface port1
end
```

6. Add a firewall address for the web server network.

```
config firewall address
edit Web-Server-Net
set type ipmask
set subnet 192.168.10.0 255.255.255.0
set associated-interface port2
end
```

7. Add an active WAN optimization security policy that includes the WAN optimization profile that enables secure tunneling and that applies virus scanning:

```
config firewall policy
edit 0
set srcintf port1
set dstintf port2
set srcaddr Client-Net
set dstaddr Web-Server-Net
set action accept
set service HTTP
set schedule always
set wanopt enable
set wanopt-detection active
set wanopt-profile Secure-wan-opt-pro
end
```

### To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
edit Client-Fgt
set ip 172.20.120.1
```

```
end
```

**3. Add an authentication group to be used for secure tunneling:**

```
config wanopt auth-group
edit Auth-Secure-Tunnel
set auth-method psk
set psk 2345678
end
```

Leave `peer-accept` at its default value.

**4. Add a firewall address for the client network.**

```
config firewall address
edit Client-Net
set type ipmask
set subnet 172.20.120.0 255.255.255.0
set associated-interface port1
end
```

**5. Add a firewall address for the web server network.**

```
config firewall address
edit Web-Server-Net
set type ipmask
set subnet 192.168.10.0 255.255.255.0
set associated-interface port2
end
```

**6. Add a passive WAN optimization policy.**

```
config firewall policy
edit 0
set srcintf port1
set dstintf port2
set srcaddr Client-Net
set dstaddr Web-Server-Net
set action accept
set service ALL
set schedule always
set wanopt enable
set wanopt-detection passive
set wanopt-passive-opt default
end
```

**7. Add a WAN optimization tunnel explicit proxy policy.**

```
configure firewall proxy-policy
edit 0
set proxy wanopt
set dstintf port1
set srcaddr all
set dstaddr all
set action accept
set schedule always
set service ALL
next
end
```

## Peers and authentication groups

All communication between WAN optimization peers begins with one WAN optimization peer (or client-side FortiGate unit) sending a WAN optimization tunnel request to another peer (or server-side FortiGate unit). During this process, the WAN optimization peers identify and optionally authenticate each other.

### Basic WAN optimization peer requirements

WAN optimization requires the following configuration on each peer. For information about configuring local and peer host IDs, see [Basic WAN optimization peer requirements on page 1006](#).

- The peer must have a unique host ID.
- Unless authentication groups are used, peers authenticate each other using host ID values. Do not leave the local host ID at its default value.
- The peer must know the host IDs and IP addresses of all of the other peers that it can start WAN optimization tunnels with. This does not apply if you use authentication groups that accept all peers.
- All peers must have the same local certificate installed on their FortiGate units if the units authenticate by local certificate. Similarly, if the units authenticate by pre-shared key (password), administrators must know the password. The type of authentication is selected in the authentication group. This applies only if you use authentication groups.

### Accepting any peers

Strictly speaking, you do not need to add peers. Instead you can configure authentication groups that accept any peer. However, for this to work, both peers must have the same authentication group (with the same name) and both peers must have the same certificate or pre-shared key.

Accepting any peer is useful if you have many peers or if peer IP addresses change. For example, you could have FortiGate units with dynamic external IP addresses (using DHCP or PPPoE). For most other situations, this method is not recommended and is not a best practice as it is less secure than accepting defined peers or a single peer. For more information, see [Basic WAN optimization peer requirements on page 1006](#).

### How FortiGate units process tunnel requests for peer authentication

When a client-side FortiGate unit attempts to start a WAN optimization tunnel with a peer server-side FortiGate unit, the tunnel request includes the following information:

- the client-side local host ID
- the name of an authentication group, if included in the rule that initiates the tunnel
- if an authentication group is used, the authentication method it specifies: pre-shared key or certificate
- the type of tunnel (secure or not).

For information about configuring the local host ID, peers and authentication groups, see [How FortiGate units process tunnel requests for peer authentication on page 1006](#) and [How FortiGate units process tunnel requests for peer authentication on page 1006](#).

The authentication group is optional unless the tunnel is a secure tunnel. For more information, see [How FortiGate units process tunnel requests for peer authentication on page 1006](#).

If the tunnel request includes an authentication group, the authentication will be based on the settings of this group as follows:

- The server-side FortiGate unit searches its own configuration for the name of the authentication group in the tunnel request. If no match is found, the authentication fails.
- If a match is found, the server-side FortiGate unit compares the authentication method in the client and server authentication groups. If the methods do not match, the authentication fails.
- If the authentication methods match, the server-side FortiGate unit tests the peer acceptance settings in its copy of the authentication group.
- If the setting is **Accept Any Peer**, the authentication is successful.
- If the setting is **Specify Peer**, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the peer name in the server-side authentication group. If the names match, authentication is successful. If a match is not found, authentication fails.
- If the setting is **Accept Defined Peers**, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the server-side peer list. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the tunnel request does not include an authentication group, authentication will be based on the client-side local host ID in the tunnel request. The server-side FortiGate unit searches its peer list to match the client-side local host ID in the tunnel request. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the server-side FortiGate unit successfully authenticates the tunnel request, the server-side FortiGate unit sends back a tunnel setup response message. This message includes the server-side local host ID and the authentication group that matches the one in the tunnel request.

The client-side FortiGate unit then performs the same authentication procedure as the server-side FortiGate unit did. If both sides succeed, tunnel setup continues.

## Configuring peers

When you configure peers, you first need to add the local host ID that identifies the FortiGate unit for WAN optimization and then add the peer host ID and IP address of each FortiGate unit with which a FortiGate unit can create WAN optimization tunnels.

### To configure WAN optimization peers - web-based manager:

1. Go to **WAN Opt. & Cache > Peers**.
2. For **Local Host ID**, enter the local host ID of **this** FortiGate unit and select **Apply**. If you add this FortiGate unit as a peer to another FortiGate unit, use this ID as its **peer** host ID.

The local or host ID can contain up to 25 characters and can include spaces.

3. Select **Create New** to add a new peer.
4. For **Peer Host ID**, enter the peer host ID of the peer FortiGate unit. This is the local host ID added to the peer FortiGate unit.
5. For **IP Address**, add the IP address of the peer FortiGate unit. This is the source IP address of tunnel requests sent by the peer, usually the IP address of the FortiGate interface connected to the WAN.
6. Select **OK**.

**To configure WAN optimization peers - CLI:**

In this example, the local host ID is named `HQ_Peer` and has an IP address of `172.20.120.100`. Three peers are added, but you can add any number of peers that are on the WAN.

1. Enter the following command to set the local host ID to `HQ_Peer`.

```
config wanopt settings
  set host-id HQ_peer
end
```

2. Enter the following commands to add three peers.

```
config wanopt peer
  edit Wan_opt_peer_1
    set ip 172.20.120.100
  next
  edit Wan_opt_peer_2
    set ip 172.30.120.100
  next
  edit Wan_opt_peer_3
    set ip 172.40.120.100
end
```

## Configuring authentication groups

You need to add authentication groups to support authentication and secure tunneling between WAN optimization peers.

To perform authentication, WAN optimization peers use a certificate or a pre-shared key added to an authentication group so they can identify each other before forming a WAN optimization tunnel. Both peers must have an authentication group with the same name and settings. You add the authentication group to a peer-to-peer or active rule on the client-side FortiGate unit. When the server-side FortiGate unit receives a tunnel start request from the client-side FortiGate unit that includes an authentication group, the server-side FortiGate unit finds an authentication group in its configuration with the same name. If both authentication groups have the same certificate or pre-shared key, the peers can authenticate and set up the tunnel.

Authentication groups are also required for secure tunneling.

To add authentication groups, go to **WAN Opt. & Cache > Authentication Groups**.

**To add an authentication group - web-based manager:**

Use the following steps to add any kind of authentication group. It is assumed that if you are using a local certificate to authenticate, it is already added to the FortiGate unit

1. Go to **WAN Opt. & Cache > Authentication Groups**.
2. Select **Create New**.
3. Add a **Name** for the authentication group.

You will select this name when you add the authentication group to a WAN optimization rule.

4. Select the **Authentication Method**.

Select **Certificate** if you want to use a certificate to authenticate and encrypt WAN optimization tunnels. You must select a local certificate that has been added to this FortiGate unit. (To add a local certificate, go to **System > Certificates**.) Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and certificate.

Select **Pre-shared key** if you want to use a pre-shared key or password to authenticate and encrypt WAN optimization tunnels. You must add the **Password** (or pre-shared key) used by the authentication group. Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and password. The password must contain at least 6 printable characters and should be known only by network administrators. For optimum protection against currently known attacks, the key should consist of a minimum of 16 randomly chosen alphanumeric characters.

5. Configure **Peer Acceptance** for the authentication group.

Select **Accept Any Peer** if you do not know the peer host IDs or IP addresses of the peers that will use this authentication group. This setting is most often used for WAN optimization with FortiGate units that do not have static IP addresses, for example units that use DHCP.

Select **Accept Defined Peers** if you want to authenticate with peers added to the peer list only.

Select **Specify Peer** and select one of the peers added to the peer list to authenticate with the selected peer only.

6. Select **OK**.

7. Add the authentication group to a WAN optimization rule to apply the authentication settings in the authentication group to the rule.

**To add an authentication group that uses a certificate- CLI:**

Enter the following command to add an authentication group that uses a certificate and can authenticate all peers added to the FortiGate unit configuration.

In this example, the authentication group is named `auth_grp_1` and uses a certificate named `Example_Cert`.

```
config wanopt auth-group
  edit auth_grp_1
    set auth-method cert
    set cert Example_Cert
    set peer-accept defined
  end
```

**To add an authentication group that uses a pre-shared key - CLI:**

Enter the following command to add an authentication group that uses a pre-shared key and can authenticate only the peer added to the authentication group.

In this example, the authentication group is named `auth_peer`, the peer that the group can authenticate is named `Server_net`, and the authentication group uses `123456` as the pre-shared key. In practice you should use a more secure pre-shared key.

```
config wanopt auth-group
  edit auth_peer
    set auth-method psk
    set psk 123456
    set peer-accept one
    set peer Server_net
  end
```

### To add an authentication group that accepts WAN optimization connections from any peer - web-based manager

Add an authentication group that accepts any peer for situations where you do not have the **Peer Host IDs** or **IP Addresses** of the peers that you want to perform WAN optimization with. This setting is most often used with FortiGate units that do not have static IP addresses, for example units that use DHCP. An authentication group that accepts any peer is less secure than an authentication group that accepts defined peers or a single peer.

The example below sets the authentication method to **Pre-shared key**. You must add the same password to all FortiGate units using this authentication group.

1. Go to **WAN Opt. & Cache > Authentication Groups**.
2. Select **Create New** to add a new authentication group.
3. Configure the authentication group:

<b>Name</b>	Specify any name.
<b>Authentication Method</b>	Pre-shared key
<b>Password</b>	Enter a pre-shared key.
<b>Peer Acceptance</b>	Accept Any Peer

### To add an authentication group that accepts WAN optimization connections from any peer - CLI:

In this example, the authentication group is named `auth_grp_1`. It uses a certificate named `WAN_Cert` and accepts any peer.

```
config wanopt auth-group
  edit auth_grp_1
    set auth-method cert
    set cert WAN_Cert
    set peer-accept any
  end
```

## Secure tunneling

You can configure WAN optimization rules to use AES-128bit-CBC SSL to encrypt the traffic in the WAN optimization tunnel. WAN optimization uses FortiASIC acceleration to accelerate SSL decryption and encryption of the secure tunnel. Peer-to-peer secure tunnels use the same TCP port as non-secure peer-to-peer tunnels (TCP port 7810).

To use secure tunneling, you must select **Enable Secure Tunnel** in a WAN optimization rule and add an authentication group. The authentication group specifies the certificate or pre-shared key used to set up the secure tunnel. The **Peer Acceptance** setting of the authentication group does not affect secure tunneling.

The FortiGate units at each end of the secure tunnel must have the same authentication group with the same name and the same configuration, including the same pre-shared key or certificate. To use certificates you must install the same certificate on both FortiGate units.

For active-passive WAN optimization you can select **Enable Secure Tunnel** only in the active rule. In peer-to-peer WAN optimization you select **Enable Secure Tunnel** in the WAN optimization rule on both FortiGate units. For information about active-passive and peer-to-peer WAN optimization, see [Manual \(peer-to-peer\) and active-passive WAN optimization on page 1](#)

For a secure tunneling configuration example, see [Example: Adding secure tunneling to an active-passive WAN optimization configuration on page 1](#).

## Monitoring WAN optimization peer performance

The WAN optimization peer monitor lists all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with. These include peers manually added to the configuration as well as discovered peers.

The monitor lists each peer's name, IP address, and peer type. The peer type indicates whether the peer was manually added or discovered. To show WAN optimization performance, for each peer the monitor lists the percent of traffic reduced by the peer in client-side WAN optimization configurations and in server-side configurations (also called gateway configurations).

To view the peer monitor, go to **WAN Opt. & Cache > Peer Monitor**.

## Web Cache Concepts

FortiGate web caching is a form of object caching that accelerates web applications and web servers by reducing bandwidth usage, server load, and perceived latency. Web caching supports caching of HTTP 1.0 and HTTP 1.1 web sites. See [RFC 2616](#) for information about web caching for HTTP 1.1.

Web caching supports caching of Flash content over HTTP but does not cache audio and video streams including Flash videos and streaming content that use native streaming protocols such as RTMP.

The first time a file is received by web caching it is cached in the format it is received in, whether it be compressed or uncompressed. When the same file is requested by a client but in a different compression format, the cached file is converted to the new compressed format before being sent to the client.

There are three significant advantages to using web caching to improve HTTP and WAN performance:

- reduced bandwidth consumption because fewer requests and responses go over the WAN or Internet.
- reduced web server load because there are fewer requests for web servers to handle.
- reduced latency because responses for cached requests are available from a local FortiGate unit instead of from across the WAN or Internet.

You can use web caching to cache any web traffic that passes through the FortiGate unit, including web pages from web servers on a LAN, WAN or on the Internet. You apply web caching by enabling the web caching option in any security policy. When enabled in a security policy, web caching is applied to all HTTP sessions accepted by the security policy. If the security policy is an explicit web proxy security policy, the FortiGate unit caches explicit web proxy sessions.

## Turning on web caching for HTTP and HTTPS traffic

Web caching can be applied to any HTTP or HTTPS traffic by enabling web caching in a security policy that accepts the traffic. This includes IPv4, IPv6, WAN optimization and explicit web proxy traffic. Web caching caches all HTTP traffic accepted by a policy on TCP port 80.

You can add web caching to a policy to:

- Cache Internet HTTP traffic for users on an internal network to reduce Internet bandwidth use. Do this by selecting the web cache option for security policies that allow users on the internal network to browse web sites on the Internet.
- Reduce the load on a public facing web server by caching objects on the FortiGate unit. This is a reverse proxy with web caching configuration. Do this by selecting the web cache option for a security policy that allows users on the Internet to connect to the web server.
- Cache outgoing explicit web proxy traffic when the explicit proxy is used to proxy users in an internal network who are connecting to the web servers on the Internet. Do this by selecting the web cache option for explicit web proxy security policies that allow users on the internal network to browse web sites on the Internet.
- Combine web caching with WAN optimization. You can enable web caching in any WAN optimization security policy. This includes manual, active, and passive WAN optimization policies and WAN optimization tunnel policies. You can enable web caching on both the client-side and the server-side FortiGate units or on just one or the other. For optimum performance you can enable web caching on both the client-side and server-side FortiGate units. In this way only uncached content is transmitted through the WAN optimization tunnel. All cached content is access locally by clients from the client side FortiGate unit.

One important use for web caching is to cache software updates (for example, Windows Updates or iOS updates). When updates occur a large number of users may all be trying to download these updates at the same time. Caching these updates will be a major performance improvement and also have a potentially large impact on reducing Internet bandwidth use. You may want to adjust the maximum cache object size to make sure these updates are cached. See [Turning on web caching for HTTP and HTTPS traffic on page 1011](#).

## Turning on web caching for HTTPS traffic

Web caching can also cache the content of HTTPS traffic on TCP port 443. With HTTPS web caching, the FortiGate unit receives the HTTPS traffic on behalf of the client, opens up the encrypted traffic and extracts content to be cached. Then FortiGate unit re-encrypts the traffic and sends it on to its intended recipient. It is very similar to a man-in-the-middle attack.

You enable HTTPS web caching from the CLI in a security policy or an explicit proxy policy that accepts the traffic to be cached using `webcache-https`. For a firewall policy:

```
config firewall policy
  edit 0
    .
    .
    .
    set webcache enable
    set webcache-https enable
    .
    .
    .
  end
```

For an explicit web proxy policy:

```
config firewall proxy-policy
  edit 0
    set proxy explicit-web
    .
    .
    .
```

```

set webcache enable
set webcache-https enable
.
.
.
end

```

The `webcache-https` field is available only if `webcache` is enabled.

Web caching for HTTPS traffic is not supported if WAN optimization or FTP proxy is enabled: i.e., if `srcintf` is `ftp-proxy` or `wanopt`.

The `any` setting causes the FortiGate unit to re-encrypt the traffic with the FortiGate unit's certificate rather than the original certificate. This configuration can cause errors for HTTPS clients because the name on the certificate does not match the name on the web site.

You can stop these errors from happening by configuring HTTPS web caching to use the web server's certificate by setting `webcache-https` to `ssl-server`. This option is available for both firewall policies and explicit web proxy policies.

```

config firewall policy
edit 0
.
.
.
set webcache enable
set webcache-https enable
.
.
.
end

```

The `ssl-server` option causes the FortiGate unit to re-encrypt the traffic with a certificate that you imported into the FortiGate unit. You can add certificates using the following command:

```

config firewall ssl-server
edit corporate-server
set ip <Web-Server-IP>
set port 443
set ssl-mode { full | half}
set ssl-cert <Web-Server-Cert>
end

```

Where:

`Web-Server-IP` is the web server's IP address.

`Web-Server-Cert` is a web server certificate imported into the FortiGate unit.

The SSL server configuration also determines whether the SSL server is operating in half or full mode and the port used for the HTTPS traffic.

You can add multiple SSL server certificates in this way. When web caching processing an SSL stream if it can find a certificate that matches the web server IP address and port of one of the added SSL servers; that certificate is used to encrypt the SSL traffic before sending it to the client. As a result the client does not generate SSL certificate errors.

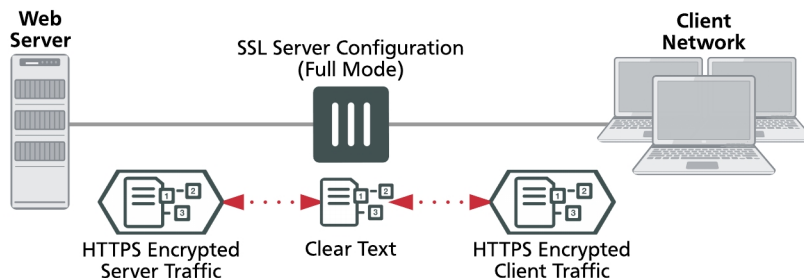

Web caching uses the FortiGate unit's FortiASIC to accelerate SSL decryption/encryption performance.

## Full mode SSL server configuration

The `ssl-mode` option determines whether the SSL server operates in half or full mode. In full mode the FortiGate unit performs both decryption and encryption of the HTTPS traffic. The full mode sequence is shown below.

### Full mode SSL server configuration

In full mode the FortiGate unit is acting as a man in the middle, decrypting and encrypting the traffic. So both the client and the web server see encrypted packets.

Usually the port of the encrypted HTTPS traffic is always 443. However, in the SSL server configuration you can set the port used for HTTPS traffic. This port is not altered by the SSL Server. So for example, if the SSL Server receives HTTPS traffic on port 443, the re-encrypted traffic forwarded to the FortiGate unit to the server or client will still use port 443.

## Half mode SSL server configuration

In half mode, the FortiGate unit only performs one encryption or decryption action. If HTTP packets are received, the half mode SSL server encrypts them and converts them to HTTPS packets. If HTTPS packets are received, the SSL server decrypts them and converts them to HTTP packets.

### Half mode SSL server configuration

In half mode, the FortiGate unit is acting like an SSL accelerator, offloading HTTPS decryption from the web server to the FortiGate unit. Since FortiGate units can accelerate SSL processing, the end result could be improved web site performance.

Usually the port of the encrypted traffic is always 443. However, in the SSL server configuration you can set the port used for HTTPS traffic. No matter what port is used for the HTTPS traffic, the decrypted HTTP traffic uses port 80.

## Changing the ports on which to look for HTTP and HTTPS traffic to cache

By default FortiOS assumes HTTP traffic uses TCP port 80 and HTTPS traffic uses port 443. So web caching caches all HTTP traffic accepted by a policy on TCP port 80 and all HTTPS traffic on TCP port 443. If you want to cache HTTP or HTTPS traffic on other ports, you can enable security profiles for the security policy and configure a proxy options profile to that looks for HTTP and HTTPS traffic on other TCP ports. To configure a proxy options profile go to **Network > Explicit Proxy**.

Setting the HTTP port to **Any** in a proxy options profile is not compatible with web caching. If you set the HTTP port to any, web caching only caches HTTP traffic on port 80.

## Web caching and HA

You can configure web caching on a FortiGate HA cluster. The recommended best practice HA configuration for web caching is active-passive mode. When the cluster is operating, all web caching sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance web caching sessions.

In a cluster, only the primary unit stores the web cache database. The databases is not synchronized to the subordinate units. So, after a failover, the new primary unit must build its web cache.

## Web caching and memory usage

To accelerate and optimize disk access and to provide better throughput and less latency, web caching uses provisioned memory to reduce disk I/O and increase disk I/O efficiency. In addition, web caching requires a small amount of additional memory per session for comprehensive flow control logic and efficient traffic forwarding.

When web caching is enabled you will see a reduction in available memory. The reduction increases when more web caching sessions are being processed. If you are thinking of enabling web caching on an operating FortiGate unit, make sure its memory usage is not maxed out during high traffic periods.

In addition to using the system dashboard to see the current memory usage you can use the `get test wad 2` command to see how much memory is currently being used by web caching. See `get test {wad | wccpd} <test_level>` on page 1 for more information.

## Changing web cache settings

In most cases, the default settings for the WAN optimization web cache are acceptable. However, you may want to change them to improve performance or optimize the cache for your configuration. To change these settings, go to **WAN Opt. & Cache > Settings**.

From the FortiGate CLI, you can use the `config wanopt webcache` command to change these WAN optimization web cache settings.

For more information about many of these web cache settings, see [RFC 2616](#).

---

## Always revalidate

Select to always revalidate requested cached objects with content on the server before serving them to the client.

## Max cache object size

Set the maximum size of objects (files) that are cached. The default size is 512000 KB and the range is 1 to 4294967 KB. This setting determines the maximum object size to store in the web cache. Objects that are larger than this size are still delivered to the client but are not stored in the FortiGate web cache.

For most web traffic the default maximum cache object size is recommended. However, since web caching can also cache larger objects such as Windows updates, Mac OS updates, iOS updates or other updates delivered using HTTP you might want to increase the object size to make sure these updates are cached. Caching these updates can save a lot of Internet bandwidth and improve performance when major updates are released by these vendors.

## Negative response duration

Set how long in minutes that the FortiGate unit caches error responses from web servers. If error responses are cached, then subsequent requests to the web cache from users will receive the error responses regardless of the actual object status.

The default is 0, meaning error responses are not cached. The content server might send a client error code (4xx HTTP response) or a server error code (5xx HTTP response) as a response to some requests. If the web cache is configured to cache these negative responses, it returns that response in subsequent requests for that page or image for the specified number of minutes.

## Fresh factor

Set the fresh factor as a percentage. The default is 100, and the range is 1 to 100%. For cached objects that do not have an expiry time, the web cache periodically checks the server to see if the objects have expired. The higher the **Fresh Factor** the less often the checks occur.

For example, if you set the **Max TTL** value and **Default TTL** to 7200 minutes (5 days) and set the **Fresh Factor** to 20, the web cache check the cached objects 5 times before they expire, but if you set the **Fresh Factor** to 100, the web cache will check once.

## Max TTL

The maximum amount of time (Time to Live) an object can stay in the web cache without the cache checking to see if it has expired on the server. The default is 7200 minutes (120 hours or 5 days) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

## Min TTL

The minimum amount of time an object can stay in the web cache before the web cache checks to see if it has expired on the server. The default is 5 minutes and the range is 1 to 5256000 minutes (5256000 minutes in a year).

## Default TTL

The default expiry time for objects that do not have an expiry time set by the web server. The default expiry time is 1440 minutes (24 hours) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

## Proxy FQDN

The fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server. This field is for information only can be changed from the explicit web proxy

configuration.

### Max HTTP request length

The maximum length of an HTTP request that can be cached. Larger requests will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

### Max HTTP message length

The maximum length of an HTTP message that can be cached. Larger messages will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

### Ignore

Select the following options to ignore some web caching features.

<b>If-modified-since</b>	By default, if the time specified by the if-modified-since (IMS) header in the client's conditional request is greater than the last modified time of the object in the cache, it is a strong indication that the copy in the cache is stale. If so, HTTP does a conditional GET to the Overlay Caching Scheme (OCS), based on the last modified time of the cached object. Enable ignoring if-modified-since to override this behavior.
<b>HTTP 1.1 conditionals</b>	HTTP 1.1 provides additional controls to the client over the behavior of caches toward stale objects. Depending on various cache-control headers, the FortiGate unit can be forced to consult the OCS before serving the object from the cache. For more information about the behavior of cache-control header values, see <a href="#">RFC 2616</a> . Enable ignoring HTTP 1.1 Conditionals to override this behavior.
<b>Pragma-no-cache</b>	Typically, if a client sends an HTTP GET request with a pragma no-cache (PNC) or cache-control no-cache header, a cache must consult the OCS before serving the content. This means that the FortiGate unit always re-fetches the entire object from the OCS, even if the cached copy of the object is fresh. Because of this behavior, PNC requests can degrade performance and increase server-side bandwidth utilization. However, if you enable ignoring Pragma-no-cache, then the PNC header from the client request is ignored. The FortiGate unit treats the request as if the PNC header is not present.
<b>IE Reload</b>	Some versions of Internet Explorer issue Accept / header instead of Pragma no-cache header when you select <b>Refresh</b> . When an Accept header has only the / value, the FortiGate unit treats it as a PNC header if it is a type-N object. Enable ignoring IE reload to cause the FortiGate unit to ignore the PNC interpretation of the Accept / header.

### Cache Expired Objects

Applies only to type-1 objects. When this option is selected, expired type-1 objects are cached (if all other conditions make the object cacheable).

### Revalidated Pragma-no-cache

The pragma-no-cache (PNC) header in a client's request can affect how efficiently the FortiGate unit uses bandwidth. If you do not want to completely ignore PNC in client requests (which you can do by selecting to

ignore Pragma-no-cache, above), you can nonetheless lower the impact on bandwidth usage by selecting **Revalidate Pragma-no-cache**.

When you select **Revalidate Pragma-no-cache**, a client's non-conditional PNC-GET request results in a conditional GET request sent to the OCS if the object is already in the cache. This gives the OCS a chance to return the 304 Not Modified response, which consumes less server-side bandwidth, because the OCS has not been forced to otherwise return full content.

By default, **Revalidate Pragma-no-cache** is disabled and is not affected by changes in the top-level profile.

Most download managers make byte-range requests with a PNC header. To serve such requests from the cache, you should also configure byte-range support when you configure the **Revalidate pragma-no-cache** option.

## Web Cache Configuration

### Forwarding URLs to forwarding servers and exempting web sites from web caching

You can go to **Network > Explicit Proxy** and use the URL match list to forward URL patterns to forwarding servers and create a list of URLs that are exempt from web caching.

#### Forwarding URLs and URL patterns to forwarding servers

As part of configuring the explicit web proxy you can configure proxy chaining by adding web proxy forwarding servers. See [Proxy chaining \(web proxy forwarding servers\)](#).

You can then use the URL match list to always forward explicit web proxy traffic destined for configured URLs or URL patterns to one of these forwarding servers. For example, you might want to forward all traffic for a specific country to a proxy server located in that country.

To forward traffic destined for a URL to a forwarding server that you have already added, go to **Network > Explicit Proxy** and select **Create New**. Add a name for the URL match entry and enter the URL or URL pattern. You can use wildcards such as \* and ? and you can use a numeric IP address. Select **Forward to Server** and select a web proxy forwarding server from the list.

You can also exempt the URL or URL pattern from web caching.

Use the following command to forward all .ca traffic to a proxy server and all .com traffic to another proxy server.

```
config web-proxy url-match
  edit "com"
    set forward-server "server-commercial"
    set url-pattern "com"
  next
  edit "ca"
    set forward-server "server-canada"
    set url-pattern "ca"
  next
  edit "www.google.ca"
    set cache-exemption enable
    set url-pattern "www.google.ca"
  next
end
```

## Exempting web sites from web caching

You may want to exempt some URLs from web caching for a number of reasons. For example, if your users access websites that are not compatible with FortiGate web caching you can add the URLs of these web sites to the web caching exempt list. You can add URLs and numeric IP addresses to the web cache exempt list.

You can also add URLs to the web cache exempt list by going to **Network > Explicit Proxy**, going to the **URL Match List**

Name	URL Pattern	Cache Exemption	Forward Server	Status	Comments
No matching entries found					

and selecting **Create New**. Add a URL pattern to be exempt and select **Exempt from Cache**.

You can also add URLs and addresses to be exempt from caching using the CLI. Enter the following command to add `www.example.com` to the web cache exempt list:

```
config web-proxy url-match
  set cache-exemption enable
  set url-pattern www.example.com
end
```

## Exempting specific files from caching

You can exempt files from being cached, so long as you specify its full URL. Enter the following command to add the URL, with the file extension (in this example, `.exe`), to the web cache exempt list:

```
config web-proxy url-match
  edit "exe"
    set url-pattern "iavs9x.u.avast.com/custom/iavs9x/20160613t1237z/avast_free_
      antivirus_setup_online.exe"
    set cache-exemption enable
```

next  
end

You cannot use wildcards to exempt file extensions in general from caching.

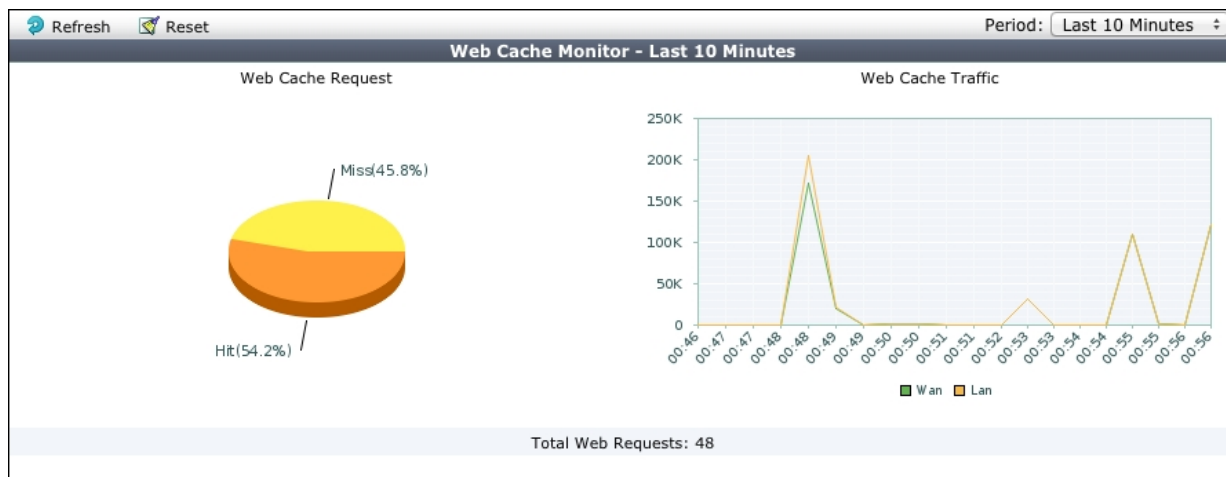

## Monitoring Web caching performance

The web cache monitor shows the percentage of web cache requests that retrieved content from the cache (hits) and the percentage that did not receive content from the cache (misses). A higher the number of hits usually indicates that the web cache is being more effective at reducing WAN traffic.

The web cache monitor also shows a graph of web traffic on the WAN and LAN. A lower WAN line on the graph indicates the web cache is reducing traffic on the WAN. The web cache monitor also displays the total number of web requests processed by the web cache.

To view the web cache monitor, go to **Monitor > Cache Monitor**.

### Web cache monitor

## Example Web caching of HTTP and HTTPS Internet content for users on an internal network

This example describes how to configure web caching of HTTP and HTTPS for users on a private network connecting to the Internet.

### Network topology and assumptions

This example includes a client network with subnet address 10.31.101.0 connecting to web servers on the Internet. All of the users on the private network access the Internet through a single general security policy on the FortiGate unit that accepts all sessions connecting to the Internet. Web caching for HTTP and HTTPS traffic is added to this security policy.

Since users on the private network have unrestricted access to the Internet and can be accessing many web servers the `webcache-https` is set to `any` and users may see error messages on their web browsers when accessing HTTPS content.

The GUI is less versatile than the CLI so the example instructions for the GUI give settings for one port for each protocol, while the CLI example shows how to use multiple ports.

The example also describes how to configure the security policy to cache HTTP traffic on port 80 and 8080 in the CLI, by adding a proxy options profile that looks for HTTP traffic on TCP ports 80 and 8080. The example also describes how to configure the security policy to cache HTTPS traffic on port 443 and 8443 using the same proxy options profile.

### Example web caching topology

### General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:
